THE COMPLETE

DICTIONARY

OF

ARTS and SCIENCES.

IN WHICH THE WHOLE CIRCLE OF

HUMAN LEARNING

IS EXPLAINED.

And the DIFFICULTIES attending the Acquisition of EVERY ART, Whether LIBERAL or MECHANICAL, are Removed,

IN THE MOST EASY AND FAMILIAR MANNER.

Among the various Branches of LITERATURE explained in this WORK are the following, viz.

AGRICULTURE	ETHICS	HYDROGRAPHY	PAINTING
ALGEBRA	FLUXIONS	HYDROSTATICS	PERSPECTIVE
ANATOMY	FORTIFICATION	LAW	PHARMACY
ARCHITECTURE	GARDENING	LEVELLING	PHILOLOGY
ARITHMETIC	GAUGING	LOGIC	PHILOSOPHY
ASTRONOMY	GEOGRAPHY	MARITIME AND	PHYSIC
BOTANY	GEOMETRY	MILITARY AFFAIRS	PNEUMATICS
CATOPTRICS	GRAMMAR	MATHEMATICS	RHETORIC
CHEMISTRY	GUNNERY	MECHANICS	SCULPTURE
CHRONOLOGY	HANDICRAFTS	MERCHANDIZE	SERIES
COMMERCE	HERALDRY	METAPHYSICS	STATICS
CONICS	HISTORY	METEOROLOGY	STATUARY
COSMOGRAPHY	HORSEMANSHIP	MUSIC	SURGERY
DIALLING	HUSBANDRY	NAVIGATION	SURVEYING
DIOPTRICS	HYDRAULICS	OPTICS	THEOLOGY, &c.

The THEOLOGICAL, PHILOLOGICAL, and CRITICAL BRANCHES, by

The Rev. TEMPLE HENRY CROKER, A. M.

Chaplain to the Right Honourable the Earl of HILLSBOROUGH.

The MEDICINAL, ANATOMICAL, and CHEMICAL,

By THOMAS WILLIAMS, M. D.

The MATHEMATICAL

By SAMUEL CLARK,

Author of an Easy Introduction to the Theory and Practice of Mechanics.

AND THE OTHER PARTS BY

Several GENTLEMEN particularly conversant in the Arts or Sciences they have undertaken to explain.

VOL. II.

BRITISH MUSEUM

THE COMPLETE DICTIONARY OF ARTS and SCIENCES.

EAG EAR

E, The ſecond vowel, and fifth letter of the alphabet. The letter E is moſt evidently derived from the old character ∃ in the ancient Hebrew and Phœnician alphabets, inverted by the Greeks to this poſition E, and not from the Hebrew He ה. From the ſame origin is alſo derived the Saxon *e*, which is the firſt letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are uſed nearly in the ſame manner as in that letter.

It has a long and ſhort ſound in moſt languages: the ſhort ſound is audible in *bed*, *fret*, *den*, and other words ending in conſonants: its long ſound is produced by a final *e*, or an *e* at the end of words, as in *glebe*, *here*, *hire*, *ſcene*, *ſphere*, *interfere*, *revere*, *ſincere*, &c. in moſt of which it ſounds like *ee*; as alſo in ſome others by coming after *i*, as in *believe*, *chief*, *grief*, *reprieve*, &c. and ſometimes this long ſound is expreſſed by *ee*, as in *bleed*, *beer*, *creed*, &c. Sometimes the final *e* is ſilent, and only ſerves to lengthen the ſound of the preceding vowel, as in *rag*, *rage*, *ſtag*, *ſtage*, *hug*, *huge*, &c. The ſound of *e* is obſcure in the following words, *oxen*, *heaven*, *bounden*, *fire*, *aire*, *maſſacre*, *maugre*, &c.

The Greeks have their long and ſhort *e*, which they call Epſilon and Eta. The French have at leaſt ſix kinds of *e*'s: the Latins have alſo a long and ſhort *e*; they alſo write *e* inſtead of *a*, as *dicem* for *dicam*, &c. and this is, no doubt, the reaſon why *a* is ſo often changed into *e*, in the præter tenſe, as, *ago*, *egi*; *facio*, *feci*, &c. E was alſo a numeral letter ſtanding for 250, according to the verſe,

E *quoque ducentos et quinquaginta tenebit.*

EAGLE, *Aquila*, in ornithology, the Engliſh name of ſeveral ſpecies of the falcon kind. See the article FALCON.

In heraldry, the eagle is accounted one of the moſt noble bearings in armoury, and according to the learned in this ſcience, ought to be given to none but ſuch as greatly excel in the virtues of generoſity and courage, or for having done ſingular ſervices to their ſovereigns; in which caſes they may be allowed a whole eagle, or an eagle naiſſant, or only the head or other parts thereof, as may be moſt agreeable to their exploits.

Among the ancients, the eagle was held ſacred to Jupiter, and on that account placed on his ſcepter. Philoſtratus, in his Themiſtocles, ſays, the Medes and Lacedæmonians took it for their enſign of royalty: and it is well known that the Romans had the greateſt reſpect for it, looking upon it as the taliſman of their ſtate, and taking it for their principal enſign. It was either of gold or ſilver, borne ſingle on the point of a pike, till the time of Conſtantine, when the empire being divided into the eaſtern and weſtern, the eagle was afterwards repreſented with two heads.

EAGLE, *Aquila*, in aſtronomy. See AQUILA.

EAGLE, in architecture, a figure of that bird anciently uſed as an attribute of Jupiter, in the capitals and friezes of the columns of the temples conſecrated to that god.

EAGLE-STONE, *Ætites*, in natural hiſtory. See the article ÆTITES.

Black EAGLE, an order of knighthood, inſtituted by the elector of Brandenburgh, in 1701, on his being crowned king of Pruſſia.

The knights of this order wear an orange-coloured ribbon, ſuſpending a black eagle.

White EAGLE, a like order in Poland, inſtituted in 1325, by Uladiſlaus V. on occaſion of the marriage of his ſon Caſimir to the daughter of the great duke of Lithuania.

The knights of this order wear a chain of gold, ſuſpending a ſilver eagle, crowned.

White EAGLE is alſo a term uſed by chemiſts for mercurius dulcis.

EAGLET, a diminutive of eagle, properly ſignifying a young eagle. In heraldry, when there are ſeveral eagles on the ſame eſcutcheon, they are termed eaglets.

EALDERMAN, or EALDORMAN, the ſame with alderman. See ALDERMAN.

EAR, *Auris*, in anatomy, the organ of hearing.

Anatomiſts generally diſtinguiſh the ear into external and internal; the greateſt part of the external ear conſiſts of

of a large cartilage, which is the baſis of all the other parts. There are two portions, the one large and ſolid, called pinna, which is the ſuperior part; the other ſmall and ſoft, called the lobe, which makes the lower part. We may likewiſe conſider two ſides in the outward ear, one turned obliquely forward, and irregularly concave; the other turned obliquely backward, and unequally convex; the foreſide is divided into four eminences and as many cavities; the firſt eminence is in the helix, which is the large folded border, or circumference of the great portion of the ear: the ſecond is the anthelix, which is the large oblong eminence ſurrounded by the helix: the third is the tragus, which is the ſmall anterior protuberance below the anterior extremity of the helix: the fourth is the antitragus, which is the poſterior tubercle below the inferior extremity of the anthelix.

The firſt cavity is the hollow of the helix; the ſecond is the depreſſion at the ſuperior extremity of the anthelix, called foſſa navicularis; the third is the concha, or great double cavity, that lies under the anthelix, the upper bottom of which is divided from the lower by a continuation of the helix, like a tranverſe criſta; and, laſtly, the meatus of the external ear at the bottom of the concha.

The backſide of the ear has only one conſiderable eminence, which is a portion of the convex ſide of the concha, the other portion being hid by the adheſion of the ear to the os temporis.

The external ear is fixed to the cranium by muſcles, or rather ligaments. The ſkin is a continuation of that which covers the neighbouring parts of the temporal region. The arteries of the external ear come anteriorly from the arteria temporalis, and poſteriorly from the occipitalis. The veins are branches of the jugularis externa. The portio dura of the auditory nerve gives off a branch which runs up behind the ear, to the backſide of which it ſends ſeveral filaments; and the trunk of the branch ſends likewiſe filaments to the meatus and foreſide of the ear. The ſecond vertebral pair ſends alſo a branch to the ear, the ramifications of which communicate with thoſe of the other.

The internal ear conſiſts chiefly of ſeveral bony pieces, which may be divided into four general parts; the external meatus auditorius; the tympanum, or barrel of the ear; the labyrinth; and the internal meatus auditorius; or it may be divided into immoveable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called incus, malleus, ſtapes, and os orbiculare, or lenticulare.

The external auditory paſſage is about half an inch in length, running obliquely from behind forward: its cavity is almoſt oval, wider at the entry than at the middle, after which it widens again by degrees: it terminates inwardly by an even circular edge, the upper part being outward, and the lower part inward. The concave ſide of this edge is grooved quite round.

The tympanum is an irregularly hemiſpherical cavity, the bottom of it being turned inward, and the mouth joined to the circular groove. It has three remarkable eminences; the firſt is a large tuberoſity lying in the very bottom of the barrel; a ſmall irregular pyramid ſituated about the tuberoſity, the apex of which is perforated, and on one ſide of the baſis two ſmall bony filaments are often found parallel. In the third eminence is a cavity ſhaped like the mouth of a ſpoon, ſituated a little towards the anterior part of the bottom of the barrel; and at a very ſmall diſtance from its point is a little bony ridge. The principal cavities in the tympanum are the opening of the maſtoid cells, the opening of the Euſtachian tube, the bony half-canal, the feneſtra ovalis and rotunda, and the ſmall hole in the pyramid.

The incus or anvil may be divided into body and branches; the body is a large ſubſtance turned forward; the branches are two; one long turned downward, the other ſhort turned backward. The malleus is a long bone with a large head, a ſmall neck, and two apophyſes, one in the neck, the other in the handle. The ſtapes is a ſmall bone, ſo denominated from its reſemblance to a ſtirrup; it is divided into the head, legs, and baſis. The orbicular or lenticular bone lies between the head of the ſtapes and extremity of the long leg of the incus, being articulated with each of theſe.

The labyrinth is divided into three parts; the anterior, called cochlea; the middle, termed veſtibulum; and the poſterior; the labyrinth, in particular, comprehends the three ſemi-circular canals: the cochlea is a ſort of ſpiral ſhell, with two ducts, formed in the anterior part of the apophyſis petroſa, like the ſhell of a ſnail. The parts to be diſtinguiſhed in it are the baſis, the apex, the ſpiral lamina, or half-ſeptum, by which its cavity is divided into two half-canals, the ſpindle round which the cochlea turns, and, laſtly, the orifice and union of the two ducts. The veſtibulum is an irregularly round cavity, leſs than the tympanum, and ſituated more inward, and a little more forward. The ſemi-circular canals are three in number; one vertical and ſuperior; one vertical and poſterior; and one horizontal.

The internal auditory hole is the backſide of the apophyſis petroſa, in ſome meaſure behind the veſtibulum and baſis of the cochlea. It is a kind of blind hole, divided into two foſſulæ; one large, the other ſmall. The large one lies loweſt, and ſerves for the portio mollis of the auditory nerve: the ſmall one is uppermoſt, and is the opening of a ſmall duct, through which the portio dura of the ſame nerve paſſes. To this latter duct Fallopius gave the name of aqueduct.

The other parts of the ear are principally the membrana tympani, the perioſteum of the barrel, the membrana maſtoidæa interna, the muſcles of the officula, the parts which complete the formation of the Euſtachian tube, the arteries, veins, and nerves.

To begin with the Euſtachian tube, otherwiſe called ductus auris palatinus, and in France generally the aqueduct, which is not to be confounded with the aquæductus Fallopii: this duct reaches from the cavity of the barrel to the root of the internal ala of the apophyſis pterygoides; it is made up of two portions, one entirely bony, and the other partly bony, partly cartilaginous, and partly membranous. The Euſtachian tube is furniſhed with three muſcles, according to Valſalva; the pterygoſtaphylinus, the ſphenopterygopalatinus, and the palatoſalpingæus, ſince called by ſome, muſculus tubæ novus Valſalvæ; its uſe is to dilate and keep open this channel, as Valſalva firſt has moſt ingeniouſly obſerved.

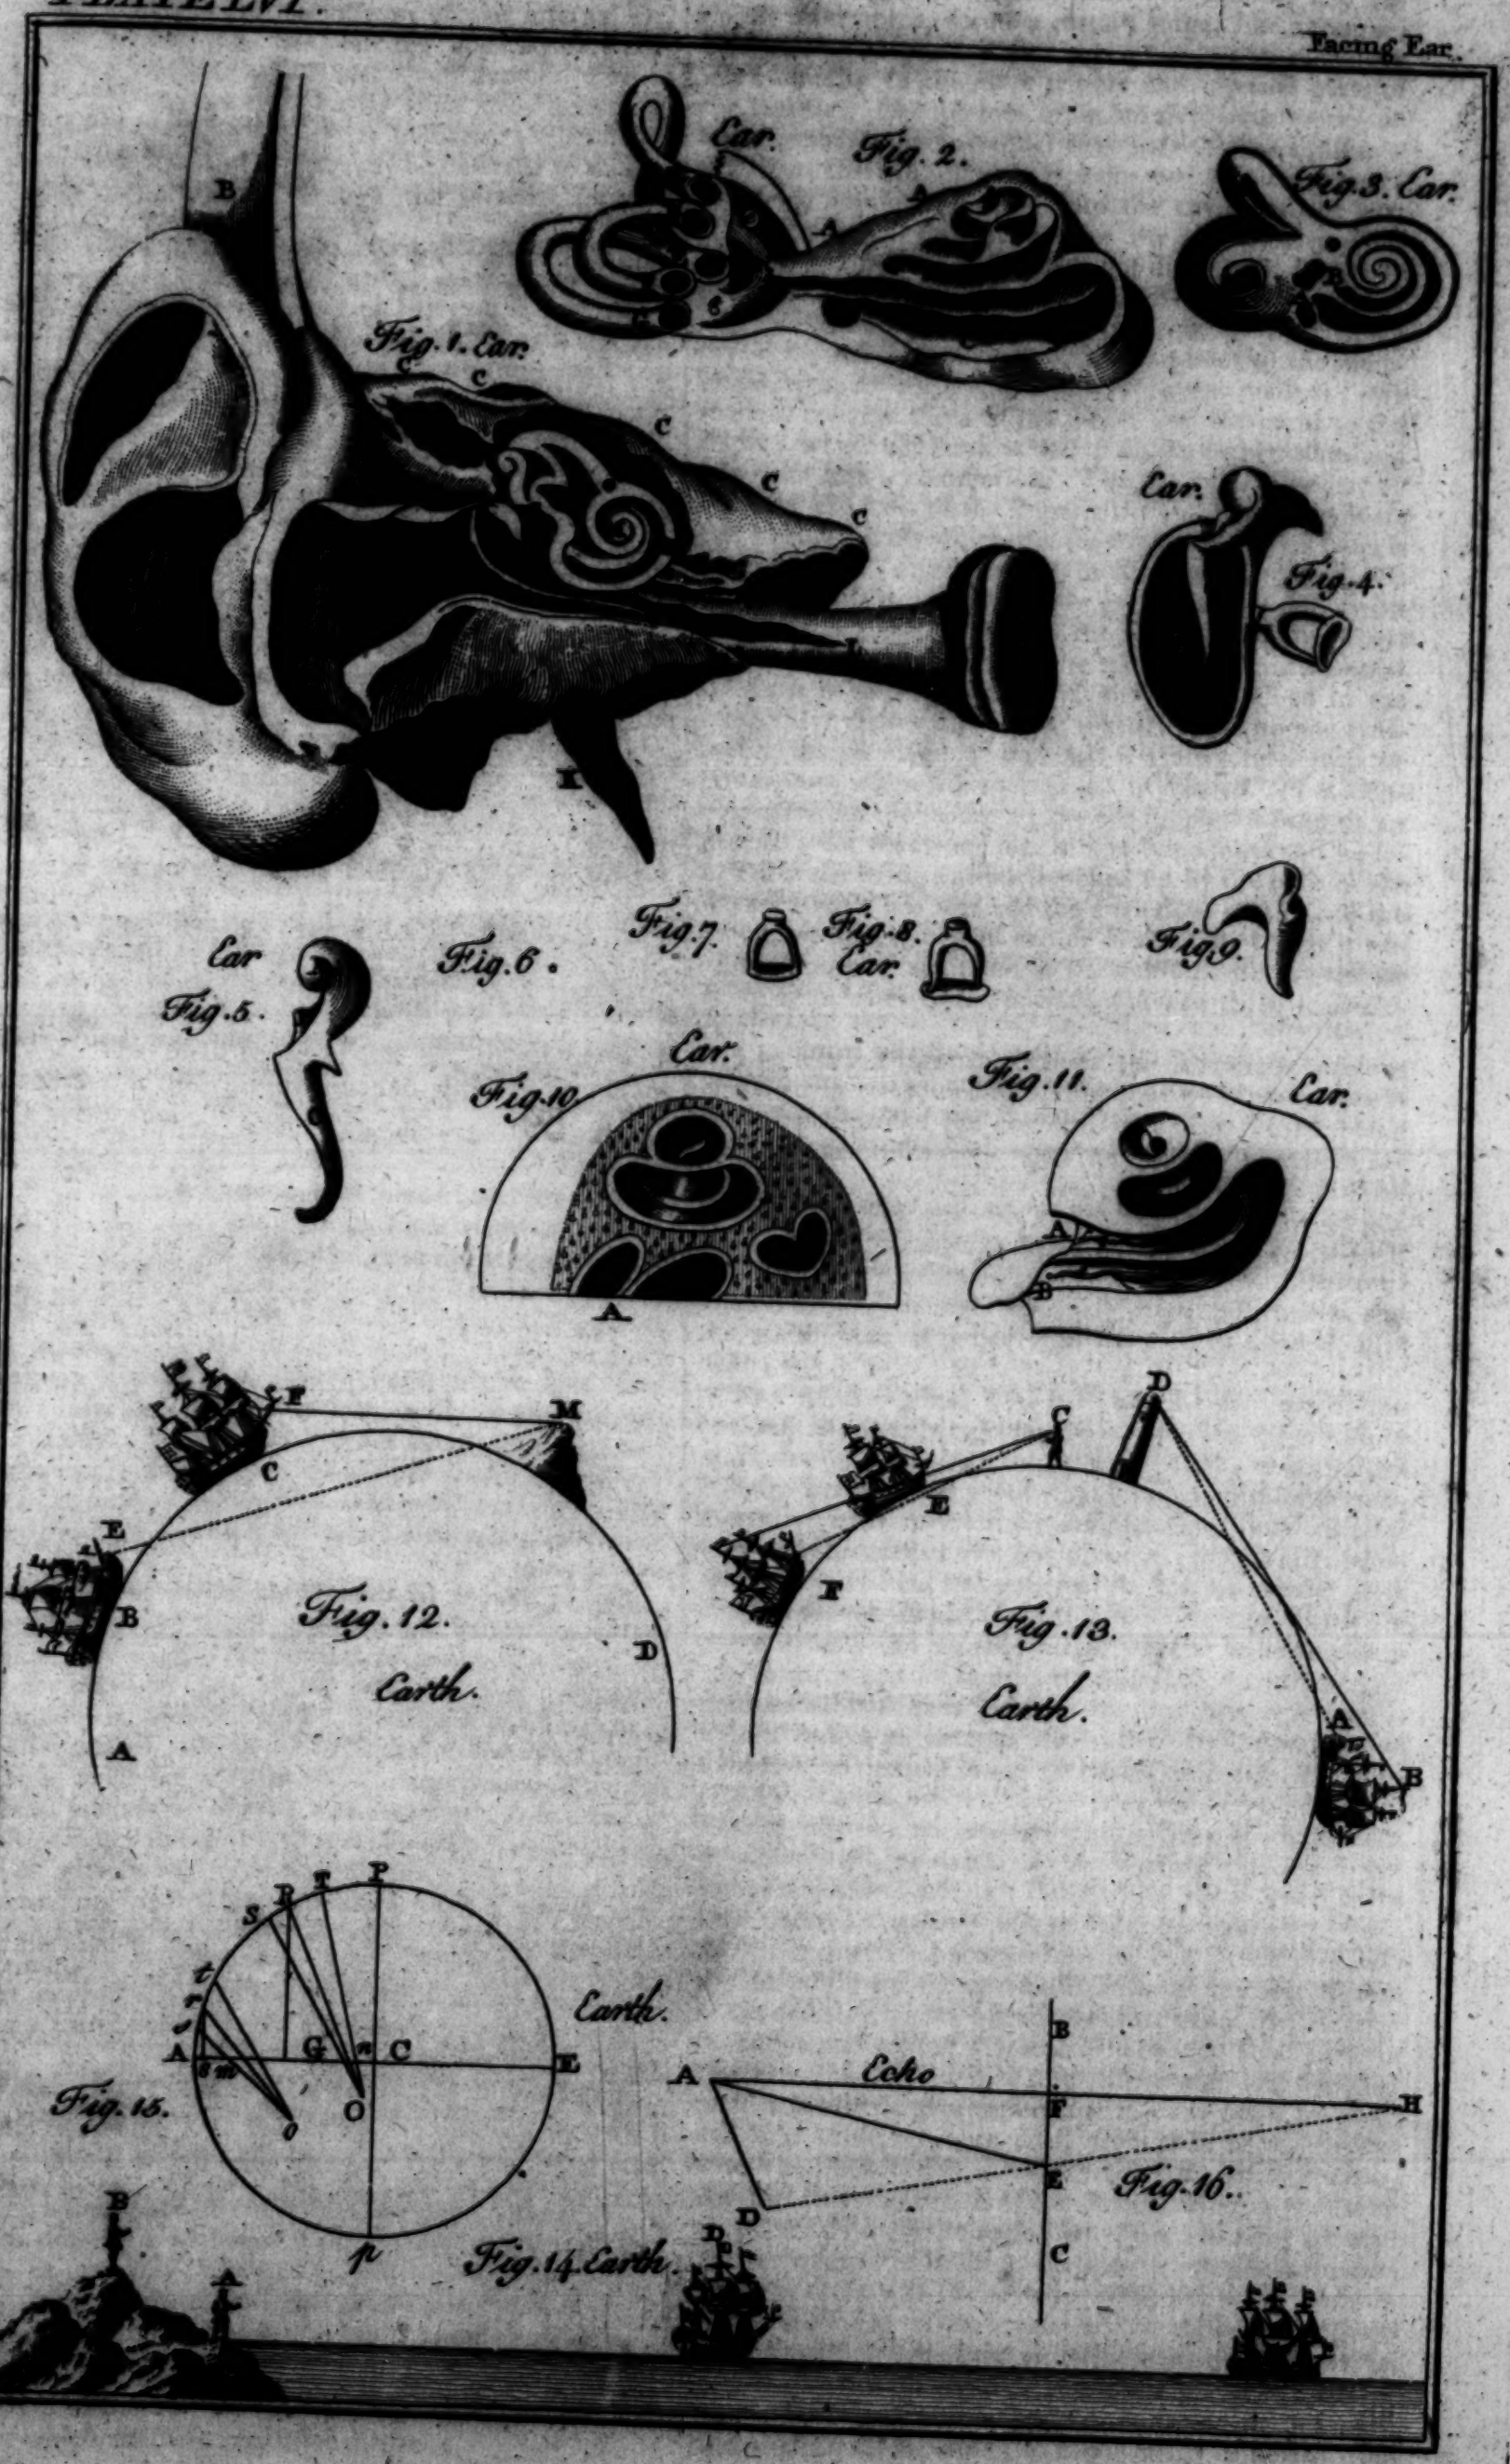
The membrana tympani is a thin, tranſparent, flattiſh pellicle, whoſe edge is round, and ſtrongly fixed in the orbicular tube. The perioſteum of the tympanum produces that of the ſmall bones; it is likewiſe continued over the two feneſtræ, and enters the Euſtachian tube. The cellulæ maſtoidææ are very irregular cavities in the ſubſtance of the maſtoid apophyſis, which communicate with each other, and have a common opening towards the inſide, and a little above the poſterior edge of the orbicular groove.

The ligaments of the officula come next in order: the incus is tied by a ſtrong ſhort ligament fixed in the point of the ſhort branch to the edge of the maſtoid opening. Between the incus and malleus we find a ſmall ſhort cartilage. The malleus is connected through the whole length of its handle, to the inſide of the membrana tympani. The malleus has three muſcles; one external, attributed to Caſſerius, and mentioned by Fabricius ab Aquapendente, is a thin faſciculus of fleſhy fibres, lying along the upper-part of the meatus auditorius, between the perioſteum and other integuments. The ſecond muſcle of the malleus is the anterior, called by Du Verney the external; it is fleſhy, long, and thin. It adheres very cloſely throughout to the Euſtachian tube; it is partly accompanied by a nerve which forms what is called the chorda tympani.

The third muſcle of the malleus is internal; it is very fleſhy and diſtinct, lying partly on the cartilaginous, and partly on the bony portion of the Euſtachian tube, and fixed by one extremity in the apophyſis petroſa; afterwards it runs along the cavity of the bony half-canal of the tympanum, where it is inveſted by a portion of the membranous or ligamentary vagina. The muſcle of the ſtapes is ſhort and thick, and lies concealed within the ſmall bony pyramid at the bottom of the tympanum. The three parts of the labyrinth are lined by a fine perioſteum, which is continued over all the ſides of their cavities,

PLATE LVI.

Facing Ear.



5 1A 59

and ſhuts the two feneſtræ of their tympanum. Through the whole extent of the perioſteum of the internal ear, eſpecially the officula, ſemi-circular canals, and half-canals of the cochlea, we diſcover a vaſt number of blood veſſels. The arteries come partly from the internal carotid, and partly from the arteria baſilaris, the ſmall capillary ramifications of which may be obſerved to accompany the auditory nerve through the internal foramen auditorium. *Winſlow.*

In order to render the foregoing deſcription of this organ the eaſier to be conceived, we have added a perſpective view of its ſeveral parts in plate LVI. where *fig.* 1. repreſents a general plan of the organ ſomewhat bigger than nature, from Le Cat. A, the external ear. B, the thin or ſquamous part of the temporal bone. C, C, C, &c. the os petroſum. D, ſemi-lunar canals. E, the maſtoid, or mamillary ſinus. F, the paſſage from the external to the internal ear. G, the ſmall bones, as the malleus, incus, and ſtapes. H, the tympanum. I, the extremity of the maſtoid proceſs. K, the ſtyloid proceſs. L, the Euſtachian tube. M, the cochlea. N, the canal of the hard portion of the auditory nerve.

Fig. 2. The labyrinth, &c. ſeveral times bigger than nature, from Du Verney. A, A, the cochlea. B, the cochlea opening into the veſtibulum. C, the cochlea opening into the tympanum. D, the veſtibulum. E, E, E, the poſterior three ſemilunar canals. F, the middle canal. G, the anterior canal. *e*, *e*, openings where the ſoft portion of the auditory nerve enters the veſtibulum.

Fig. 3. The cochlea, from Le Cat, almoſt as large again as the life. A, the ſpiral canal of the cochlea, leading to the tympanum. B, a ſpiral canal, leading to the veſtibulum.

Fig. 4. The ſmall bones of the ear, articulated with one another in their proper ſituation with the membrane of the tympanum.

Fig. 5. The malleus. A, its head. B, its neck. C, its handle.

Fig. 6. The os orbiculare.

Fig. 7. The inferior part of the ſtapes.

Fig. 8. The ſuperior back part of the ſtapes.

Fig. 9. The inner face of the incus.

Fig. 10. A ſection of the cochlea, comprehending the foramen of the auditory nerve. A, the double bottom of the internal auditory foramen.

Fig. 11. A ſection of the cochlea with the blood veſſels, the membraneous part of the ſpiral lamina being deſtroyed, except at the top; from Caſſebohm. A, the ſpiral winding of the cochlea, leading to the veſtibulum. B, the ſpiral canal, leading to the tympanum.

As to the uſes of the different parts of the ear, Du Verney tells us, that we may juſtly conſider the external ear as a kind of natural horn, the clean and ſmooth cavity of which ſerves to collect ſounds, and conſequently render their impreſſion on the other organs of hearing ſtronger. Some are of opinion that the direct lines of ſound, whilſt inſinuating themſelves into the ſinuſes of the ear, are there ſeveral times reflected, before they reach the concha; and that theſe ſinuſes and repeated reflections ſerve to augment the impreſſion. The motion of the muſcles of the external ear is a matter attended with a good deal of obſcurity; but yet it ſeems probable that the concha muſt, by their action, be either contracted or dilated, according to the impetus or faintneſs of the tremulous motions of the air. The meatus of the ear, by redoubling the reflexions, renders the vibrations more briſk; and the obliquity of its ſtructure not only guards the membrana tympani againſt the injuries of the air, but is alſo the reaſon why the ſurface of the meatus itſelf is larger than it would otherwiſe be. That ſpecies of wax, in the cartilaginous part of the meatus, retains any extraneous ſubſtances, or inſects, which might poſſibly convey themſelves into the ear, and injure the membrana tympani: but nevertheleſs it is often productive of great inconveniences; for, unleſs the ear were frequently cleanſed, this viſcid ſubſtance would be accumulated in too large a quantity, and at laſt hinder the tremulous motions of the air from reaching the membrana tympani; from which deafneſs very often happens.

The cartilaginous meatus, which is winding and variouſly interrupted, forms a certain ridge, like a tongue, before the concha. This ridge propels the reflexions more directly to the more remote and internal parts of the meatus. The nervous branches diſtributed upon the cartilaginous meatus render that part of ſo exquiſite a ſenſation, that we inſtantly feel the moſt minute extraneous body inſinuating itſelf into the cavity of the ear. The membrana tympani receives the various tremulous motions of the air, and, when not diſordered, faithfully conveys them to the other parts of the internal ear; but it performs theſe functions in conſequence of its being dry, thin, and diaphanous. The agitations of the membrana tympani are communicated to the malleus; the malleus conveys them to the incus, and the incus to the ſtapes; whoſe agitation at laſt puts the os petroſum and labyrinth into a commotion. The muſculus ſtapedis, by drawing the baſis of the ſtapes a little outwards, renders the pellicle, with which the ſuperior part of this baſis is covered, tenſe; and according as it renders it more or leſs ſo, it gives it a proportionably greater or leſs diſpoſition for receiving the tremulous motions of the membrana tympani. On the ſides of the tympanum are two meatuſes; it is not improbable that the air contained in the tympanum retires into theſe, when the membrana tympani is drawn inwards; and that it again returns into the tympanum, when this membrane is relaxed. The conveyance from the palate to the ear ſupplies a fund of air neceſſary for renewing that in the tympanum. The feneſtra ovalis being entirely blocked up by the baſis of the ſtapes, after it has received the tremulous motions of the other two bones, and of the air in the tympanum, it can eaſily communicate them to the veſtibulum, and the air in it, and thence to the cochlea and the three ſemi-circular ducts.

The feneſtra rotunda receives the tremulous motions of the air in the tympanum, and conveys them to that in the inferior part of the cochlea, in which the air being ſtrongly compreſſed, for want of an exit, is excellently calculated for putting the lamina ſpiralis into commotions; and thus the tremulous motions of the air are conveyed to the immediate organ of hearing itſelf; which is comprehended under the general name labyrinth, which conſiſts of two principal parts, the cochlea and the veſtibulum, together with their three ſemi-circular ducts.

The ſpiral lamina, which is a principal part of the cochlea, is not only calculated for receiving the vibratory motions of the air, but its ſtructure ought to be looked upon as a convincing proof, that it is qualified for accommodating itſelf to all their different modifications; for ſince it is broader at the beginning of its firſt circumvolution, than at the extremity of its laſt, its broader parts are adapted to languid vibrations, which are productive of grave tones; and *vice verſa*, that, when its narrow parts are ſtruck, their vibrations are lively, and conſequently produce acute ſounds: ſuch is the ſtructure of the veſtibulum and ſemi-circular ducts that the impreſſion of ſounds is heightened in their winding meanders, and conſequently better qualified for putting the nerves, diſperſed in theſe places, into a commotion. Each of theſe ducts reſembles two trumpets, whoſe narrow extremities are joined together; and the ſame thing holds good as to theſe ducts, as has been ſaid of the ſpiral lamina.

The connection between hearing and ſpeech is uſually accounted for by the communication of the ſoft portion of the auditory nerve, with thoſe branches of the fifth pair of nerves, which are diſtributed to the parts deſtined for the formation of the voice: for this reaſon it is ſaid that men and birds can mutually incite each other to ſing; and that thoſe who are deaf, from their birth, muſt of courſe be likewiſe dumb. Anatomiſts are alſo of opinion, that the communication of the ſecond vertebral pair with the external ear, is the reaſon why, upon hearing the leaſt noiſe, we turn our heads to the quarter whence it comes; and why the whole of the body is diſpoſed to various motions, according as the cauſes of the noiſe are imagined to be hurtful or beneficial to itſelf; and ſince theſe nerves communicate with thoſe of the lungs and heart, we become ſenſible of proportionable alterations in our pulſe and reſpiration, according to the diverſity of noiſes. But

all are not agreed, with regard to the effects of theſe different communications.

EAR, among gardeners, a name given to the leaves that firſt appear from the ſeed, which differ conſiderably from other leaves.

EAR-WIG, *Forficula*, in zoology. See the article FORFICULA.

EARL, a Britiſh title of nobility, next below a marquis, and above a viſcount. Earls were anciently called comites, becauſe they were wont *comitari regem*, to wait upon the king for counſel and advice.

EARL *Marſhal of England*, is a great officer who had anciently ſeveral courts under his juriſdiction, as the court of chivalry, and the court of honour. Under him is alſo the herald's office or college of arms. He hath ſome pre-eminence in the court of Marſhalſea, where he may ſit in judgment againſt thoſe who offend within the verge of the king's court. This office is of great antiquity in England, and anciently of greater power than now; and has been for ſeveral ages hereditary in the moſt noble family of Howard.

EARNEST, *Antiæ*, money advanced to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain loſes his earneſt; and if the perſon who received the earneſt give back, he is to return the earneſt double. But with us, the perſon who gave it is, in ſtrictneſs, obliged to abide by his bargain; and in caſe he decline it, is not diſcharged upon forfeiting his earneſt, but may be ſued for the whole money ſtipulated.

EARTH, in geography, this terraqueous globe whereon we live, conſiſting of land and water.

That the earth is nearly ſpherical may be ſhewn by the following obſervations. 1. When we are at ſea on board a ſhip, we may be out of ſight of land, when the land is near enough to be viſible, if it were not hid from our eye by the convexity of the water; thus let ABCD (plate LVI. *fig.* 12.) repreſent part of the globe of the earth; let M be the top of a mountain; this cannot be ſeen by a perſon on board a ſhip at B, becauſe a line drawn from M to his eye at E is intercepted by the convexity of the water: but let the ſhip come to C, and then the mountain will be viſible, becauſe a line may be drawn from M to his eye at F. 2. The higher the eye is, the farther will the view be extended: it is very common for ſailors from the top of the maſt of a ſhip to diſcover land or ſhips at a greater diſtance than they can do when they ſtand upon deck: thus (*fig.*13.) the top of the tower D may be ſeen from B, the top of the maſt, when it cannot be ſeen from A, by reaſon of its being hid by the convexity of the water. 3. When we ſtand upon the ſhore, the higheſt part of a ſhip is viſible at the greateſt diſtance: if a ſhip is going from us out to ſea, we ſhall continue to ſee the maſt, after the hull or body of the ſhip diſappears, and the top of the maſt will continue to be ſeen longeſt; if a ſhip be coming towards us, the top of the maſt comes firſt into view, and we ſee more and more of it, till at laſt the hull appears: thus let the eye be at C, when a ſhip is as far off as at F, only the top of the maſt is viſible, the hull is hid behind the water; when the ſhip is nearer, as at E, the hull may alſo then be ſeen. If the ſurface of the ſea were a flat, (*fig.*14.) a line might be drawn from any object ſituated upon it, as the ſhip D, to the eye, whether placed high or low, at A or B: in this caſe, any object upon the earth or ſea would be viſible at any diſtance which was not ſo great as to make the appearance of it too faint, or the angle under which it appears too ſmall, to be ſeen by us: an object would be viſible at the ſame diſtance, whether the eye were high or low: not the higheſt but the largeſt objects would be viſible to the greateſt diſtance, ſo that we ſhould be able to ſee the hull of a ſhip further off than the maſt: all which is contrary to experience. 4. The convexity of the water may be ſeen upon any ſtill water, as upon a river which is extended in a ſtraight line, a mile or two in length; a little boat upon the water may be ſeen, at a mile diſtance, by a man whoſe eye is any height above the water: but if he ſtoops down and lays his eye near the water, he will find the ſurface thereof riſing up in ſuch a manner as to cover the boat, and intercept his view of it. 5. Several navigators have ſailed quite round the globe; not in an exact circle, for this the winding of the ſhores, the land running out in many places into the ſea, would not admit of; but going in and out, as the ſhores happen to lie, they have held on the ſame courſe, and come home on a different ſide from that they firſt ſet out from: thus, Ferdinand Magellan, ſetting out on the weſt-ſide of Spain, continued ſailing weſtward till he returned home on the eaſt-ſide of Spain; our Sir Francis Drake, Capt. Dampier, Lord Anſon, and others, have done the like; the courſe they have ſome of them run is marked upon ſeveral maps and globes: theſe proofs are ſufficient to evince the roundneſs of the water. That the earth is alſo round is evident, if we conſider that the ocean is diffuſed all over the globe, ſo as to divide the earth as it were into large iſlands; and that the ſurface of the earth is not very much higher than the ſea, is evident from the courſe of rivers, which at a moderate eſtimate are computed to have not above one mile fall in running a thouſand miles, and have their ſhores pretty much of the ſame height; as alſo from the height of mountains, which are none of them found to be above three or four miles higher than the ſurface of the ſea: theſe experiments prove the earth and ſea to have a convex ſurface every-where. 6. All the appearances of the heaven, both at land and ſea, are the ſame as they would be if the earth were a globe, which proves it to be of that ſhape; and laſtly in eclipſes of the moon, which are cauſed by the ſhadow of the earth falling upon the moon, as will appear under the aricle ECLIPSE. This ſhadow is always circular, whatever ſituation the earth is in at that time: now a body can be no other than a globe, which in all ſituations caſts a circular ſhadow: it is true the ſurface of the earth is not an exact geometrical globe, becauſe it ſinks into vallies in ſome places, and riſes into mountains in others; but theſe inequalities upon its ſurface are as inconſiderable, when compared with the magnitude of the earth, as the little aſperities upon the rind of an orange are to the bulk of the orange; and accordingly we find that mountains and vallies upon the ſurface of the earth cauſe no irregularities in its ſhadow, in a lunar eclipſe, but the circumference thereof is even and regular, as if it were caſt by a body exactly globular: the diameter of the earth is about 8000 Engliſh miles; the higheſt mountain is not four miles higher than the ſurface of the ſea, which is about a 2000th part of the earth's diameter: thus it appears that the higheſt mountain bears no greater proportion to the bulk of the earth than a grain of duſt does to a common globe.

But, though the earth be ſpherical, yet it is not a true ſphere, but an oblate ſpheroid, flatted towards the poles; that is, the axis of the earth is not ſo long as the diameter of the equator. This was diſcovered by the following accident:

In 1672, M. Richer, going to Cayenne, in order to make aſtronomical obſervations, found, that his pendulum clock, which at Paris had been regulated to the mean motion of the ſun, when carried to this iſland, which is about five degrees diſtant from the equator, loſt every day two minutes and twenty-eight ſeconds. At his return he reported this experiment, and, as it ſeemed to be of ſome importance, it immediately engaged the attention of the greateſt mathematicans.

But they preſently preceived that the ſlowneſs of the pendulum muſt proceed from a diminution of the preſſure of gravity; and, conſequently, that the preſſure of gravity was leſs at Cayenne than at Paris: for, when a pendulum of a clock departs in its motion from the perpendicular, the force which cauſes it to return is gravity; whence it follows, that the greater the degree of gravity is, the quicker its motion will be, and *vice verſa*: and, as the motion of the pendulum was ſlower at Cayenne than at Paris, the preſſure of gravity muſt be leſs. Indeed, in warm climates all rods of metal will lengthen, whence the rod of the pendulum muſt be ſomewhat longer at Cayenne than at Paris; and, conſequently, its oſcillations ſlower. But as we know in what proportion heat will lengthen pendulums, and, conſequently, how much it retards their motion, we are ſatisfied that the heats of Cayenne are not ſufficient to ſolve this phænomenon; but it muſt, in general, flow from a diminution in the preſſure of gravity.

But from whence could proceed the cauſe of this diminution of gravity? Undoubtedly from this: every body, or particle of matter, that deſcribes a circle round a center, makes a continual effort to recede from that center. It is this force that ſtrains a ſling with a ſtone in it, while you whirl it round, and were its force ſtrong enough, would even break the ſling; this effort is called the centrifugal force; to this all revolving bodies are ſubject, and if they perform their revolution in the ſame time, it is proportional to the greatneſs of the circle they deſcribe.

Now, ſince the earth revolves round its own axis in twenty-four hours, all the bodies or particles of matter which compoſe it will deſcribe circles; and conſequently each will, more or leſs, partake of this centrifugal force, in proportion to the circle it deſcribes. And, becauſe the particles under the equator deſcribe the greateſt circle, therefore they will have the greateſt degree of centrifugal force; and the nearer the poles a particle is ſituated, the leſs will be its degree of centrifugal force; becauſe the circle it deſcribes will be ſmaller. The whole effect of this force tends to make bodies recede from the center of the circles they deſcribe, and a part of it is oppoſite to that of gravity, whoſe force every-where impels bodies towards the center of the earth. This part of the centrifugal force continually increaſes the nearer you approach to the equator, becauſe under the circle, not only the centrifugal force is directly contrary to that of gravity, but alſo the circles deſcribed by the revolving bodies are there the greateſt. The great Sir Iſaac Newton and M. Huygins carried their calculations ſo far as to compare the quantity of the centrifugal force with gravity, and found that under the equator it was $= \frac{1}{289}$ part of gravity; that is, a body under the equator loſt the 289th part of its weight: then, conſidering that the waters of the ſea are in æquilibrio all over the earth, and ſuppoſing the earth to be formed of a homogeneous and fluid matter, or that had originally been ſo, they undertook to determine its figure by the laws of hydroſtratics.

That this fluid matter might be at reſt, and the waters continue equal on each ſide, the weight of a column of water, continued from the center to the equator, muſt of conſequence be equal to that of a column of water continued from the center to the pole; for otherwiſe they would not continue in æquilibrio; but, as the matter which formed the column continued from the center to the equator, was rendered lighter by the centrifugal force than that which compoſed the column which was continued from the center of the pole; it follows that the column at the equator muſt be longer than at the poles, and conſequently the earth is flattened at the poles.

This theory was greatly confirmed by the figure of the planet Jupiter; for as this planet is much greater than the earth, his diameter being 81155 miles, whereas the earth's is only 7964 miles; and as the revolution of this planet about its own axis is performed in 9 hours, 56 min. it follows, that the equatorial parts of his ſurface muſt have a prodigious velocity, which muſt conſequently cauſe him to be a ſpheroidical figure. Accordingly the ingenious Mr. Pound diſcovered that the axis of the equator was to that of the poles, as 12 to 13.

Here the queſtion might have reſted, and had probably never been accurately ſolved, had it not been for the oppoſition it met with from M. Caſſini, though he afterwards ingeniouſly owned his miſtake. This gentleman, having meaſured the meridian of France from Dunkirk to Colliours, in Rouſſillon, declared, contrary to the opinion of all the mathematicians, that the earth, inſtead of being flattened, was lengthened towards the poles; that is, inſtead of being an oblate, it was a prolate ſpheroid, higher at the poles by about 95 miles. Sir Iſaac Newton remonſtrated, that, if this was the figure of the earth, bodies muſt be lighter, and a pendulum longer at the equator than in France, about half an inch; and that the diameter of the earth's ſhadow from ſouth to north muſt exceed its diameter from eaſt to weſt by 2 min. 46 ſec. a twelfth part of the moon's diameter; all which was manifeſtly contrary to fact and obſervation: but even this from ſo great a man could not intirely remove all the ſcruples of ſome mathematicians, as they were ſupported by the obſervations and experiments of ſo diligent an artiſt as M. Caſſini.

At length the king of France, at an expence becoming a monarch who delighted in cultivating the ſciences, ſent two companies of mathematicians, the one to the equator, and the other to the arctic circle, in order to decide this affair, and accurately determine the true figure of the earth.

Problem. Let APEpA (*fig.* 15.) be a meridian of the earth, Pp its axis and the height of the pole, in any two places on that meridian, as S and T at a given diſtance, but not very far from each other, to be truly determined; and the ſame thing to be done at two other places, s, t, a conſiderable diſtance from the former, either on the ſame or any other meridian: it is required from thence to find the ratio of the earth's equatorial and polar diameters, and the length of each of them, allowing the form of the earth to be ſpheroidical.

Solution. Let R and r be mean latitudes, between ST and st; RG, rg, ordinates to the axis AE; and RO, ro, the radius of curvature at R and r; then it is plain the angles AnR, Amr, expreſſing thoſe latitudes will be given; as alſo the little angles SOT, $ſot$, equal to the difference of latitudes at ST and st, exceeding near, becauſe the curvature in the elliptical arch ST, by reaſon of the ſmallneſs of the arch, can no where ſenſibly differ from the mean curvature at R; and the ſame may be ſaid in reſpect of the arch st. Therefore, putting AC$=b$, PC$=c$, GG$=u$, ST$=$D; angle TOS$=$E, ſine of AnR$=$S, radius $=1$, and $p=3{,}14159$, &c. we have $E : 180^\circ :: D : \frac{180\,D}{E}$, the length of a ſemi-circle, whoſe radius is equal to RO; $p : 1 : \frac{180\,D}{E} : \frac{180\,D}{Ep} =$ RO, which from hence is given. But it is proved by the writers on fluxions, that this radius RO is alſo equal to $\frac{\overline{b^4+u^2\times cc-bb}^{\frac{3}{2}}}{cb^4}$; wherefore, putting $\frac{180\,D}{pE}$, or RO$=$G$^{\frac{3}{2}}$, we have $b^4+u^2\times\overline{cc-bb}=c^{\frac{2}{3}}b^{\frac{8}{3}}\times$G: but now to exterminate u^2, from the nature of the curve, we have RG $=\frac{c\sqrt{bb-uu}}{b}$, and G$n=\frac{ccu}{bb}$; therefore as $\frac{c\sqrt{bb-uu}}{b}$ to $\frac{ccu}{bb}$:: S the ſine of GnR to $\sqrt{1-SS}$ its coſine; hence $u^2=\frac{\overline{1-SS}\times b^4}{\overline{1-SS}\times bb+SScc}$, which, ſubſtituted in the other equation, brings it to $\frac{b^4c^2}{\overline{1-SS}\times bb+SScc}=Gc^{\frac{2}{3}}b^{\frac{8}{3}}$, or $\overline{1-SS}\times bbG+ccSSG=\overline{c^4b^4}^{\frac{1}{3}}$. Therefore, if st be put $=d$, angle $tos=e$, ſine of the angle A$mr=s$, and $\frac{180\,d}{ep}=g^{\frac{1}{2}}=r$; it is manifeſt that $\overline{c^4b^4}^{\frac{1}{3}}$ will alſo be equal to $\overline{1-ss}\times bbg+ccssg$; hence by comparing theſe two values of $\overline{c^4b^4}^{\frac{1}{3}}$ we get $\frac{c}{b}=1-\frac{\overline{G-g}^{\frac{1}{2}}}{S^2G-s^2g}$ for the ratio required; which when E and e, the two differences of latitudes, are equal, will become $\frac{c}{b}=1-\frac{\overline{D^{\frac{2}{3}}-d^{\frac{2}{3}}}^{\frac{1}{2}}}{S^2d^{\frac{2}{3}}-s^2d^{\frac{2}{3}}}$ becauſe then G is to g, as $D^{\frac{2}{3}}$ is to $d^{\frac{2}{3}}$. But now, in order to find the values of b and c from hence, put f inſtead of $\frac{G-g}{S^2G-s^2g}$, or $\frac{D^{\frac{2}{3}}-d^{\frac{2}{3}}}{S^2D^{\frac{2}{3}}-s^2d^{\frac{2}{3}}}$, then will $\frac{c}{b}=\sqrt{1-f}$, and $cc=b^2\times\overline{1-f}$; whence, by ſubſtituting theſe values in the equation $\overline{1-ss}\times bbg+ccssg=\overline{c^4b^4}^{\frac{1}{3}}$ (above found) there comes out $b=\frac{g^{\frac{2}{3}}\times\overline{1-fss}^{\frac{2}{3}}}{1-f}=\frac{r\times\overline{1-fss}^{\frac{2}{3}}}{1-f}$, becauſe $g^{\frac{2}{3}}=r$: therefore $c=r\times\frac{\overline{1-fss}^{\frac{2}{3}}}{\overline{1-f}^{\frac{1}{2}}}$. Now if f be ſmall, in reſpect of unity, then $r\times\overline{\frac{1-fss}{1-f}}^{\frac{1}{2}}$ or b, will be nearly

nearly $= r + rf \times \frac{1-3ss}{2}$; but when this is ſo, it is evident, in caſe $E = e$, that $D^{\frac{2}{3}} - d^{\frac{2}{3}}$, muſt alſo be very ſmall; therefore, putting $\frac{D-d}{d} = m$, or $\frac{D}{d} = 1 + m$, we ſhall have $D^{\frac{2}{3}} - d^{\frac{2}{3}} = \frac{2md}{3}$ very nearly, and therefore (by ſubſtitution) $\frac{c}{b} = 1 - \frac{m}{3 \times SS - ss}$, $b = r + \frac{mr \times 2 - 3ss}{3 \times S^2 - s^2}$, and $b - c = \frac{mr}{3 \times SS - ss}$ very nearly.

By obſervations made under the artic circle, by Meſſrs. de Maupertuis, Clairaut, Camus, Le Monier, the Abbé Outhier, and M. Celſius of Upſal; the length of a degree in whoſe middle the pole was elevated 66° 31′ was found to be 57437 toiſes (a toiſe is = 6,408 Engliſh feet): but by thoſe of Mr. Picard, as corrected by the ſaid gentlemen, the length of one near Paris, where the mean latitude was 48° 50′ appears to be only 56925 toiſes, differing from the former by 512 toiſes. Now, to determine the earth's true dimenſions by the foregoing theorems applied to theſe obſervations, let S = Nat. ſine of 66° 31′ s = that of 48° 50′ D = 57437, d = 56925, and E = e = 1; then r = 3261600, $\frac{D-d}{d} = m = ,009$ $\frac{c}{b}$ $(= 1 - \frac{m}{3 \times SS - ss})$ = .9892, b = 3272300, c = 3236500, and $b - c$ = 35800 toiſes; wherefore it appears, that the length of the earth's axis, from pole to pole, is 6473000 toiſes, or 7863,2 Engliſh miles; and that the difference between it and the equatorial diameter is about $\frac{1}{572}$ part of the former, or 86,8 miles.

EARTH, in gardening and huſbandry, if good ſhould be of a blackiſh colour, gravelly, fat, pliant, or eaſy to be digged; it ſhould be neither cold nor light, it ought to have no ill ſmell or taſte, and it ſhould be of the ſame quality three or four feet deep for trees, which if they have not that depth, will languiſh and decay after they have been planted ſix years. Fruit trees will thrive in a leſs depth, and they generally produce the moſt generous fruits, when their roots ſpread near the ſurface of the earth.

Huſbandmen call that new earth which lying three or more feet deep, never ſerved to the nouriſhment of any plant; or earth that has been a long time built upon, though it had formerly bore; earth likewiſe of a ſandy loamy nature, where cattle have been a long time fed, may be accounted ſuch, and be of excellent uſe for moſt ſorts of plants, eſpecially if it has been thrown up in heaps to grow richer.

EARTH, in chemiſtry, the fourth of the chemical elements, or principles, into which bodies are reſolvable by fire.

Magnetiſm of the EARTH. Dr. Knight thinks the earth may be conſidered as a great load-ſtone, whoſe magnetical parts are diſpoſed in a very irregular manner, and that the ſouth-pole of the earth is analogous to the north-pole in magnets; that is, the pole by which the magnetical ſtream enters. He obſerves, that the earth might become magnetical by the iron-ores it contains; and notwithſtanding it might have remained unmagnetical, unleſs ſome cauſe had exiſted capable of making that excellent matter, producing magnetiſm, move in a ſtream thro' the earth; yet he thinks that ſuch a cauſe does really exiſt. For if the earth revolves round the ſun in an ellipſis, and the ſouth-pole of the earth is directed towards the ſun at the time of its deſcent, a ſtream of repellent matter will thereby be made to enter at the ſouth-pole, and come out at the north. And he ſuggeſts, that the earth's being in its perihelion in the winter, may be one reaſon why magnetiſm is ſtronger in this ſeaſon than in ſummer. Hence alſo the doctor imagines it probable, that the earth's magnetiſm has been improving ſince the creation, and that this may be one reaſon why the uſe of the compaſs was not diſcovered ſooner. See the article MAGNET.

Theory of the EARTH. The earth in its natural and original ſtate Des Cartes, Burnet, Woodward, and Whiſton, ſuppoſe to have been perfectly round, ſmooth, equable; and they account for its preſent rude and irregular form principally from the great deluge. See the article DELUGE.

Mr. de Buffon, arguing from the ſpheroidical figure of the earth, and the laws of hydroſtatics, ſuppoſes that the earth, as well as the other planets, are parts ſtruck off from the body of the ſun by the colliſion of comets, and conſequently, when the earth aſſumed its form, it was in a ſtate of liquefaction by fire. Of this, ſays he, we ſhall be the more eaſily convinced, when we conſider the nature of the matter contained in the body of the earth, the greateſt part of which, as ſand and clays, are vitrified, or vitrifiable ſubſtances; and, on the other hand, when we reflect upon the impoſſibility of the earth's being ever in a ſtate of fluidity produced by water, ſince there is infinitely more land than water; and beſides, water has not the power of diſſolving ſand, ſtones, and other ſubſtances, of which the earth is compoſed. How far the inequalities in the face of the earth, the beds of rivers, lakes, &c. and the various ſtrata in its internal parts, ſerve to confirm this hypotheſis, may be ſeen in Hiſtoire Naturelle, &c. tom. i. by M. de Buffon, and in the articles MOUNTAIN, RIVER, STRATA, &c.

EARTH-BANKS, in huſbandry, &c. are a very common fence about London, and in ſeveral other parts of England. Where ſtones are not to be had cheap, theſe are to be preferred to all other fences, both for ſoundneſs and laſting.

The beſt manner of making them is this: dig up ſome turf in a graſſy place, a ſpit deep, or nearly the breadth of the ſpade, and about four or five inches thick; lay theſe turfs, with the graſs outward, even by a line on one ſide, and on the back-ſide of theſe lay another row of turf, having a foot ſpace of ſolid ground on the outſide to prevent the bank from ſlipping in, if it ſhould be any ways faulty. On the outſide of this make a ditch, or elſe let the ſides be lowered both ways with a ſlope two feet deep. and there will be no paſture loſt by the fence, becauſe it will bear graſs on both ſides.

The earth that is dug out of the ditches, or from the ſlope, muſt be thrown in between the two rows of turf, till the middle is made level with the reſt: then lay on two more rows of turf in the ſame manner; and with more of the earth fill up and make level as before. Let this method be continued till the bank is raiſed four feet high, or more, if neceſſary, only obſerving, that the higher it is to be carried, the wider the foundation muſt be made. As the bank is carried up, the ſides muſt not be raiſed perpendicular, but ſloping, inward both ways, ſo that at the top it may be about two feet and a half wide. This ſort of fence, when made with leſs care, and faced with clay, is left naked, and ſerves very well in ſome places; but, when it is thus managed with the turf, the joinings of the ſeveral pieces are hid in a little time, by the growth of the graſſy part of the turf on each ſide, and it makes a beautiful fence, of as green and pleaſant a colour as the reſt of the field.

The great improvement upon this plan is the planting quickſets, or young white-thorn plants, in the middle of the top of the bank. The earth on each ſide of theſe may be raiſed up with a ſort of wall, and the rain that falls all preſerved for the plants. This plenty of water, and depth of fine earth, makes the young plants grow quicker and more vigorouſly than any other way; and the moſt beautiful of all hedges is propagated this way. When this ſort of hedge is young, there muſt be placed on each ſide of it a ſhort dry fence, of about a foot high, to keep the ſheep from cropping theſe young plants, but this may be taken away after a little time.

There is one caution neceſſary in regard to the making theſe banks, which is, that they muſt never be made in a very dry ſeaſon, becauſe, if much rain ſhould follow, the earth of the bank would ſwell aud burſt out, or ſpoil the ſhape of the bank; but, if this ſhould happen, it is eaſily repaired. This beautiful fence may be made at a ſmaller price than thoſe unaccuſtomed to theſe things may imagine. In good digging ground, where men work at about fourteen pence per day, it may be made and planted with quick for two ſhillings a pole. It may be made proper for the keeping in of deer, only by the ſmall addition of planting, at every eight or ten feet diſtance, a poſt a little ſlanting, with a mortiſe in it; let this ſtand about two feet above the bank, and into the mortiſes, all along, put a rail made of a bough of any tree; no deer

will ever go over this, nor can they creep under it, as they often do, when a pale tumbles down. The quick, on the top of this bank, may be kept clipped, and will grow very thick, and afford the beſt ſhelter for cattle of any fence in uſe with us.

EARTHING, in agriculture and gardening, ſignifies the covering of ſhrubs and plants, as vines, celery, &c. with earth.

EARTHQUAKE, in natural hiſtory, a violent agitation, or trembling of ſome conſiderable part of the earth, generally attended with a terrible noiſe like thunder, and ſometimes with an eruption of fire, water, winds, &c.

Earthquakes are allowed to be the greateſt and moſt terrible phœnomena of nature, there being no ſecurity againſt their effects, when they come with the laſt degree of violence.

There are two ſorts of earthquakes; the one cauſed by the action of ſubterraneous fires and the exploſion of the volcanos, which are not felt but at ſmall diſtances, and at the times that the volcanos are agitated, or before they begin to open: and the other from air. When the materials that form ſubterraneous fires come to be fermented, heated, and inflamed, the fire makes efforts on all ſides; and if it does not naturally find an outlet, it raiſes the earth, and makes a paſſage for itſelf by throwing it off, by which means a volcano is produced, the effects of which are repeated, and they laſt in proportion to the quantity of inflammable matter it contains: if this matter be inconſiderable, there may happen a raiſing of the ground, a commotion, and an earthquake, without any volcano being formed by that means: the air, produced and rarefied by the ſubterraneous fire, may likewiſe find ſmall outlets by which it may eſcape; and in this caſe there will only happen an earthquake without any eruption or volcano. But when there is a large quantity of inflammable matter, and when it is locked up and confined by ſolid and compact ſubſtances, there happens a commotion and a volcano too: but all theſe commotions cauſe no more than the firſt ſort of earthquakes, and can only ſhake a ſmall ſpace of ground. A very violent eruption, for inſtance, of Mount Ætna, will cauſe an earthquake over the whole iſland of Sicily; but it will never extend to three or four hundred leagues diſtance. When ſome new vents of fire have been formed in Mount Veſuvius, there are felt at the ſame time earthquakes at Naples, and in the neighbourhood of the volcano; but theſe concuſſions have never ſhaken the Alps, nor been communicated to France, or other countries remote from Veſuvius: in this manner earthquakes, produced by means of volcanos, are confined to a narrow ſpace; which is properly the effect of the re-action of the fire, and they ſhake the earth, juſt as the exploſion of a powder magazine cauſes a ſenſible concuſſion at ſeveral leagues diſtance.

But there is another ſort of earthquakes very different as to their effects, and, probably, as to their cauſes; and theſe are ſuch as are felt at conſiderable diſtances, and which ſhake a long tract or ſlip of ground without any volcano or eruption appearing. We have inſtances of earthquakes which are felt at the ſame time in England, France, Germany, and even in Hungary; and theſe always extend a great deal more in length than in breadth; they ſhake a tract of ground with more or leſs violence in different places; and they are almoſt always accompanied with a dull noiſe, much like that of a large carriage that rolls along ſwiftly.

In order to underſtand thoroughly what may be the cauſes of this kind of earthquake, we muſt remember that all inflammable matters capable of exploſion, ſuch as gun-powder, generate a large quantity of air; that this air, produced by the fire, is in a ſtate of very great rarefaction; and that by means of this compreſſion, in which it finds itſelf in the bowels of the earth, it muſt produce very violent effects. Let us, therefore, ſuppoſe that at a very conſiderable depth, as a hundred or two hundred fathoms, there be found pyrites and other ſulphureous ſubſtances, and that by the fermentation produced by the filtering of the waters, or other cauſes, theſe happen to take fire, let us ſee what will be the reſult; in the firſt place, theſe ſubſtances are not regularly diſpoſed in horizontal ſtrata; on the contrary, they are contained in the perpendicular fiſſures, in the caverns at the foot of theſe fiſſures, and in other places where the water can act, and into which they can penetrate: theſe ſubſtances, coming to take fire, will generate a large quantity of air, whoſe ſpring being compreſſed in a little room, as in that of a cavern, will not only ſhake the ſuperior ground, but ſeek for paſſages to eſcape by and to extricate itſelf. The paſſages that preſent themſelves, are the caverns and canals formed by the ſubterraneous waters and rivulets; the rarefied air will violently precipitate into all the paſſages that are open, and form a furious wind in theſe ſubterraneous cavities, the noiſe of which ſhall be heard at the ſurface of the earth, accompanied with concuſſions thereof; this ſubterraneous wind produced by the fire will extend as far as theſe cavities, and cauſe an earthquake more or leſs violent, in proportion as it is remote from the fire, and finds paſſages more or leſs narrow: this motion being performed lengthwiſe, the concuſſion will be in the ſame direction, and the earthquake felt in a long zone or tract of ground. This air will cauſe no eruption, or volcano, becauſe it will find ſufficient room to dilate itſelf, or, rather, becauſe it will find outlets, and iſſue out in form of wind or vapour: and even ſhould it be denied, that there are actually any ſubterraneous paſſages by which this air and theſe vapours can eſcape, we may eaſily conceive, that in the very place where the firſt exploſion happens, the ground being raiſed up to a conſiderable height, the adjoining place muſt be divided and rent aſunder horizontally, in order to correſpond with the primary motion, which is ſufficient to make paſſages that may communicate the motion to a very great diſtance. This explication agrees with all the phœnomena. An earthquake is not felt in the very ſame inſtant in two diſtant places, for inſtance, a hundred or two hundred leagues; there is no external eruption of fire cauſed by theſe earthquakes that reach to ſome diſtance, and the noiſe that accompanies them, almoſt always points out the progreſſive motion of the ſubterraneous fire.

What has been ſaid may be farther confirmed by connecting it with other facts. It is well known, that mines exhale vapours independently of the winds produced by the current of the waters, and that there are often obſerved in them currents of unwholeſome air and ſuffocating exhalations; and beſides, there are holes, abyſſes, and deep lakes on the earth, that produce winds, as the Lake of Boleſlaw, in Bohemia.

Earthquakes, it is true, are a great deal more frequent in places where volcanos are than elſewhere; as in Sicily and Naples; and it is well known from obſervations made at different times, that the moſt violent earthquakes happen at the time of the greateſt eruptions of volcanos. *Buffon's Hiſtoire Naturelle.*

Earthquakes may be produced artificially, by mixing equal quantities of ſulphur and the filings of iron, and beating them together, with an addition of water, into a kind of paſte; and burying the whole three or four feet under the ſurface of the earth; and in ſeven or eight hours time the earth will begin to tremble, crack, and ſmoke, and burſt out into flames.

EASEL-PIECES, a denomination given by painters to ſuch pieces as are contained in frames, in contradiſtinction from thoſe painted on cielings, &c.

EASEMENT, in law, a privilege or convenience which one neighbour has of another, whether by charter or preſcription, without profit: ſuch are paſſages thro' his lands, a ſink, or the like. Theſe, in many caſes, may be claimed.

EAST, one of the four cardinal points of the world; being that point of the horizon where the ſun is ſeen to riſe when in the equinoctial. See COMPASS, HORIZON, EQUINOCTIAL, &c.

EAST is alſo frequently compounded with other words, as Eaſt-Indies, eaſt-dial, eaſt-wind, &c. to ſignify their being ſituated towards the eaſt. See the articles INDIES, DIAL, WIND, &c.

EASTER is the great feſtival of the anniverſary commemoration of our Saviour's reſurrection; which, for its antiquity and excellence, challenges the precedence of all others.

The Greeks and Latins call it *paſcha*, originally an Hebrew word, ſignifying a paſſage, applied to the feaſt of

the paſſover held by the Jews much about the ſame time. In Engliſh it is called Eaſter, from a goddeſs of that name, worſhipped by the Saxons in the month of April.

It was in conformity to the cuſtom of the Jews, who were commanded by God himſelf to celebrate the paſſover in the firſt month, and on the fourteenth day of that month in the even, that the primitive fathers ordered that the fourteenth day of the moon from the calendar new moon, which immediately follows after the twenty-firſt of March, at which time the vernal equinox happened upon that day, ſhould be deemed the Paſchal full-moon, and that the Sunday after, becauſe our Saviour roſe on the day after the Jewiſh paſſover, ſhould be Eaſter-day; and it is upon this account that our Rubric has appointed it upon the firſt Sunday after the firſt full-moon immediately following the twenty-firſt day of March, upon which day, at that time, the vernal equinox happened: whence it appears that the true time of celebrating Eaſter, according to the original inſtitution of the feaſt of the paſſover, as well as according to the intent of the council of Nice, was to be the firſt Sunday after the firſt full-moon immediately following the vernal equinox, or when the ſun entered into the firſt point of Aries: and this was the principal view pope Gregory had, when he reformed the calendar, to celebrate Eaſter according to the intent of the Nicene council: and as the new-ſtyle has been ordered by act of parliament to be uſed in Great-Britain for the future, it will be neceſſary to ſhew the method of finding Eaſter, according to this method of computation, which may be performed by the following rule.

Find the epact for the year propoſed, and, if it be leſs then 24, ſubtract it from 74; but if it be 24, it muſt be taken from 73; alſo, if the epact be 25, and the golden number between 12 and 19, both numbers incluſive, the epact muſt be taken from 73, and the remainder will be Eaſter limit, or the day of the Paſchal full-moon. If the limit do not exceed 31, the day of the full-moon will be in March; but if it exceeds 31, it will be in April, the Sunday after which full-moon will be Eaſter-day.

But to ſave the trouble of calculation, we ſhall inſert the following table, by which Eaſter-day may be found by inſpection from the preſent time, till the year 1899 incluſive, according to the Gregorian method.

A TABLE to find EASTER till the year 1899 incluſive.

SUNDAY LETTERS.							
G.Numb.	A.	B.	C.	D.	E.	F.	G.

To make uſe of the preceding table, find the Sunday letter for the year in the uppermoſt line, and the golden number, or prime, in the firſt column; and in the common angle of meeting, you have the day of the month on which Eaſter falleth that year. But note, that the name of the month is ſet on the left hand, or juſt with the figure, and followeth not, as in other tables, by deſcent, but collateral.

EASTERN, an appellation given to whatever relates to the eaſt: thus we ſay, eaſtern amplitude, eaſtern church, &c. See AMPLITUDE, CHURCH, &c.

EAVES, in architecture, the margin or edge of the roof of an houſe; being the loweſt tiles, ſlates, or the like, that hang over the walls, to throw off water to a diſtance from the wall. See the articles WALL and ROOF.

EAVES LATH, a thick feather-edged board, generally nailed round the eaves of a houſe for the lowermoſt tiles, ſlates, or ſhingles, to reſt on.

EBDOMARIUS, in eccleſiaſtical writers, an officer formerly appointed weekly to ſuperintend the performance of divine ſervice in cathedrals, and preſcribe the duties of each perſon attending in the choir, as to reading, ſinging, praying, &c.

EBENUS, the ebony-tree. See the article EBONY.

EBIONITES, in church hiſtory, heretics of the firſt century, ſo called from their leader Ebion.

They held the ſame errors with the Nazarenes, united the ceremonies of the Moſaic inſtitution with the precepts of the Goſpel, obſerved both the Jewiſh Sabbath and Chriſtian Sunday, and in celebrating the euchariſt, made uſe of unleavened bread. They abſtained from the fleſh of animals, and even from milk. In relation to Chriſt, ſome of them held that he was born, like other men, of Joſeph and Mary, and acquired ſanctification only by his good works. Others of them allowed, that he was born of a virgin, but denied he was the word of God, or had any exiſtence before his human generation. They ſaid he was, indeed, the only true prophet, but yet a mere man, who by his virtue had arrived at being called Chriſt, and the Son of God. They alſo ſuppoſed, that Chriſt and the devil were two principles, which God had oppoſed to each other. Of the New Teſtament, they only received the Goſpel of St. Matthew, which they called the Goſpel according to the Hebrews.

EBONY, *Ebenus*, in botany, a tree ſuppoſed to be of the palm-kind, the wood of which is imported from different countries of the Eaſt and Weſt-Indies.

Its wood is extremely ſolid, and capable of a fine poliſh; and, therefore, much uſed in toys and marquetry.

EBRBUHARITES, a kind of Mahometan monks, ſo called from their founder Ebrbuhar.

EBRILLADE, in the manege, a check of the bridle given to the horſe by a jerk of one rein, when he refuſes to turn. Some confound the ebrillade with the ſaccade.

EBULLITION, the ſame with boiling. See BOILING.

EBULLITION is alſo uſed in a ſynonymous ſenſe with effervеſcence. See the article EFFERVESCENCE.

ECCHYMOSIS, a livid, brown, or dark ſpot in the ſkin, cauſed by extravaſated fluids, when the capillaries are broken by a contuſion.

The word is formed from the Greek εκχυω, to pour out, and αιμα, blood; or perhaps from εξ, out, and χυμος, juice or humour.

ECCLESIA, in law, ſignifies a church or parſonage. See the articles CHURCH and PARSONAGE.

ECCLESIASTES, a canonical book of the Old Teſtament, the deſign of which is to ſhew the vanity of all ſublunary things.

It was compoſed by Solomon, who enumerates the ſeveral objects on which men place their happineſs, and then ſhews the inſufficiency of all worldly enjoyments.

The Talmudiſts make king Hezekiah to be the author of it; Grotius aſcribes it to Zorobabel, and others to Iſaiah; but the generality of commentators believe this book to be the produce of Solomon's repentance, after having experienced all the follies and pleaſures of life.

ECCLESIASTICAL, an appellation given to whatever belongs to the church: thus we ſay, eccleſiaſtical polity, juriſdiction, hiſtory, &c.

ECCLESIASTICUS, an apocryphal book, generally bound up with the Scriptures, ſo called from its being read in the church, *eccleſia*, as a book of piety and inſtruction, but not of infallible authority.

The author of this book was a Jew, called Jeſus the ſon of Sirach. The Greeks call it the wiſdom of the ſon of Sirach.

ECCOPE, in ſurgery, the ſame with amputation.

ECCOPROTICS, in pharmacy, the ſame with gentle cathartics and evacuants. See CATHARTICS and EVACUANTS.

ECHARPE, in the military art. See the article BATTERY.

ECHEVIN, *Scabinus*, in the French and Dutch polity, a magiſtrate elected by the inhabitants of a city or

town, to take care of their common concerns, and the decoration and cleanlineſs of the city.

ECHINITES, in natural hiſtory, the name by which authors call the foſſile centronia, frequently found in our chalk pits.

ECHINOPS, or ECHINOPUS, glove thiſtle, in botany, a genus of plants, the flower of which is compound; conſiſting of a great number of floſcules or ſmall flowers, divided into ſeveral acute ſegments: there is no pericarpium: the ſeed, which is ſingle, is of an ovato-oblong figure, narrower at the baſe, with an obtuſe hairy apex.

The roots and ſeeds of this plant are ſaid to be attenuant and diuretic.

ECHINUS, in zoology, a name frequently uſed for the erinaceus, or common hedge-hog. See ERINACEUS.

ECHINUS, in architecture, a member or ornament near the bottom of the Ionic, Corinthian, and Compoſite capitals.

ECHIUM, viper's bugloſs, in botany, a genus of plants, the flower of which conſiſts of a ſingle petal, the tube being very ſhort, and the limb erect, growing gradually wider at the extremity, where it is divided into five unequal ſegments; the two upper-ſegments are longer than the reſt, and the loweſt one is ſmall, acute, and reflex; there is no pericarpium, inſtead of which the cup becomes rigid, and contains in it four roundiſh and obliquely acuminated ſeeds.

A powder of the root of this plant is recommended againſt epilepſies: it is alſo a ſudorific, vulnerary, and preſcribed againſt the eryſepilas.

ECHO, a ſound reverberated, or reflected to the ear from ſome oppoſing body.

The word is formed from the Greek ηχεω, to ſound.

In order to account for the nature of echoes, we muſt conſider, that ſound is perceived as coming from that place, from which, as a center, the pulſes are propagated. This is well known by experience: but to illuſtrate this matter, let A (plate LVI. *fig.* 16.) be the center from whence any ſound is directly propagated, and ſtrikes againſt any plain obſtacle C B, ſufficiently large; draw A F perpendicular to B C, and produce it to H, ſo that it may be A F = F H; the ſound reflected will be perceived as coming from the point H.

For let A E be the incident ray impinging againſt the obſtacle B C in the point E; from E draw the ray E D, in ſuch a manner that the angle C E D may be equal to the angle F E A, or that the angle of incidence may be equal to the angle of reflection; then will E D be the reflected ray of ſound; and, if produced, will paſs thro' the point H; for the angle F E H = C E D = F E A: therefore in the triangles A F E and E F H, ſince the angles of one are reſpectively equal to the ſides of the other, and the ſide F E is common to both, the ſides of one triangle will be reſpectively equal to the ſides of the other; and therefore H F = A F; wherefore the reflex ſound will be heard by a perſon at D, as coming from the point H.

As the place of the auditor, or point D, approaches towards A, the caſe will conſtantly be the ſame with reſpect to the center of ſound H; the triangles will ſtill be equal, and all their angles and ſides reſpectively; therefore, when D coincides with A, the reflex ſound, or echo, will be heard from the point H, which was to be demonſtrated.

The ſame ſound therefore is heard twice by an auditor at D; firſt by the direct ray at A D; and ſecondly by the reflex ray A E D; provided the difference between A D and A E D be ſufficiently great, that the direct and reflex ſound do not in the ſame ſenſible moment of time affect the ear: for if the reflex ſound arrive at the ear before the impreſſion of the direct ſound ceaſes, the ſound will not be double, only rendered more intenſe.

We know by experience, if more than 9 or 10 ſyllables be produced in a ſecond, the ſounds will not be diſtinct and articulate; therefore, that the reflex ſound may not be confounded with the direct ſound, there ought to be at leaſt the ninth part of a ſecond between the times of their appulſe to the ear. But in the ninth part of a ſecond the ſound runs through the ſpace of $\frac{1142}{9} = 127$ feet; the difference therefore between A D and A E D muſt not be leſs than 127 feet, for the echo to be diſtinctly heard at D.

Hence alſo it follows, that a perſon ſpeaking or uttering a ſentence in A aloud, in order to obſerve the echo by reflection from the obſtacle B C, ought to ſtand at leaſt 73 or 74 feet from it, that is, A F = 74; and ſince, at the common rate of ſpeaking, we pronounce not above 3 and $\frac{1}{2}$ ſyllables per ſecond, or read more than twenty lines of Engliſh poetry per minute; therefore, that the echo may return juſt as ſoon as the three ſyllables are expreſſed, we muſt have twice A F equal to about 1000 feet; or the ſpeaker muſt ſtand about 500 feet from the obſtacle B C; and ſo in proportion for any other number of ſyllables.

ECHO, in architecture, is applied to certain vaults and arches, generally of elliptical or parabolical figures, erected to produce artificial echoes.

ECHO, in poetry, a kind of compoſition, wherein the laſt words or ſyllables of each verſe contain ſome meaning, which, being repeated apart, anſwer to ſome queſtion or other matter contained in the verſe, as in this beautiful one from Virgil:

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

The elegance of an echo conſiſts in giving a new ſenſe to the laſt words; which reverberate, as it were, the motions of the mind, and by that means affect it with ſurprize and admiration.

ECHOMETER, in muſic, a kind of ſcale, having ſeveral lines divided on it, to find the intervals and ratios of ſounds.

The word is derived from the Greek ηχω, ſound, and μετρεω, to meaſure.

ECLECTICS, *Eclectici*, ancient philoſophers, who, without attaching themſelves to any particular ſect, ſelected whatever appeared to them the beſt and moſt rational.

Potamon of Alexandria was the firſt of the eclectics: he lived in the reigns of Auguſtus and Tiberius; and being tired with the ſcepticiſm of the Pyrrhonians, he reſolved upon a ſcheme that would allow him to believe ſomething, but without being ſo implicit as to ſwallow any entire hypotheſis.

ECLECTOS, the ſame with what is more uſually called linctus. See LINCTUS.

ECLIPSE, in aſtronomy, a privation of the light of ſome luminary, by the interpoſition of an opaque body, either between it and the eye, or between it and the ſun.

The word is derived from the Greek εκλειπω, to leave or forſake.

All dark bodies, expoſed to the direct light of the ſun, caſt a ſhadow behind them; which is nothing but the privation of light in the ſpace oppoſite to the ſun, by reaſon of the ſun's rays being intercepted by the opaque body: and as the globes of the earth and moon are both opaque bodies, which borrow all their light from the ſun, when either interpoſes, the other muſt in ſome meaſure be obſcured, as the earth (plate LVII. *fig.* 1.) at A, and the moon in B.

Hence it appears, that a ſolar eclipſe is cauſed by the interpoſition of the moon betwixt the ſun and the earth; and a lunar one, by that of the earth betwixt the ſun and moon.

Let S repreſent the ſun, D the earth, M the moon, and E her ſhadow, by which it is evident there can be no line drawn from any part of the ſun to any point in the ſpace I H, upon the earth's ſurface, but will fall upon the globe of the moon; and, ſince the moon is a dark body, it will not ſuffer any ray to paſs through or illuminate the ſpace I H; therefore that part of the earth muſt be deprived of the ſun's light. It is to be noted, that this can never happen but when the moon is in conjunction with the ſun; for at no other time is her ſhadow caſt upon the earth.

The moon being leſs than the earth, her ſhadow can never cover the whole globe, only a part of it, ſuch as I H; and a total darkneſs happens only to thoſe inhabitants on whom the ſhadow falls. The circumjacent places will be illuminated with ſome of the ſun's beams, called

called the penumbra, or a lucid partial ſhadow; which will have different degrees of illumination, according to the diſtance from the center of the real ſhadow. The inhabitants where this penumbra falls will only ſee a part of the ſun's diſk obſcure, which will appear to be more or leſs, in proportion as they are ſituated nearer or farther remote from the center: without this penumbra all the ſun's body will be ſeen at the ſame time, and no eclipſe perceived at all.

Let S (*fig.* 2.) repreſent the ſun in the equinoctial, and E the earth; then will A be the moon conjoined with the ſun to the ſouth pole; B a true conjunction at the earth's center, or in the equator; and C the moon conjoined with the ſun at the north pole.

Now it is manifeſt, when the moon is at B, her ſhadow falls in the torrid zone; and conſequently muſt take away the ſun's light from that part of the globe; when at the ſame time to the north and ſouth poles only part of the ſun's body will be darkened: and when the moon is centrally conjoined at C, the ſun may be totally eclipſed at the north pole, when at the ſame time to the ſouth part of the world he is free from the leaſt obſcuration. Hence the penumbral cone is determined in this manner:

Let A (*fig.* 3.) repreſent the ſun, E the moon, D the earth, C the moon's opaque ſhadow, and AED a right line joining the three centers; draw the line FG, from the ſuperior limb of the ſun to the earth's ſurface, touching the inferior limb of the moon; and the line HI from the inferior limb of the ſun, touching the ſuperior limb of the moon; and they will interſect each other in the point K; which point will be the vertex, and the line KN the axis of the penumbral cone. About which, if the line KG or KI be made to revolve, it will deſcribe the limits of the penumbra upon the earth's ſurface, and is here repreſented by the faint ſhadow LM.

To know how much of the earth's ſurface can be involved in this penumbra, firſt, let us ſuppoſe the angle of the cone, as demonſtrated by Dr. Keill in his Aſtronomical Lectures, page 116, without ſenſible error, equal to the apparent diameter of the ſun; then in the triangle KOE, right-angled at O, is given the ſemi-diameter of the moon OE, and the ſemiangle of the cone OKE, to find the diſtance of the moon's center from the vertex K; which when known, added to the moon's diſtance from the earth, will give the whole height of the ſaid cone from the earth's center: then in the oblique triangle DKI are given the ſides DK and DI, together with the angle DKI; hence will be found the angle NDI, whoſe meaſure is the arch IN, the ſemi-diameter of the penumbra upon the earth.

After the ſame manner may be found the quantity of the earth involved in the real ſhadow. But if the apparent diameter of the ſun exceed that of the moon, the real ſhadow will not reach the earth: in this caſe there may be a central eclipſe of the ſun, but not a total one. This is called an annular eclipſe; the moon's body appears in the ſun's diſk, ſurrounded by a bright luminous circle. Such a one was obſerved by Clavius at Rome, April the 9th, 1567; and ſuch another paſſed over the city of Edinburgh on February 18, 1736-7, in the evening.

As it is evident there can be no eclipſe of the ſun, but when the moon is in the change; for then only the moon is in oppoſition to the ſun, and near the earth's ſhadow: ſo there can be no eclipſe of the moon but at the time of the full. And ſince there is a new and a full moon every month, it will be proper to give a reaſon, why there is not alſo an eclipſe at thoſe times every month. If the moon's orbit lay in the plane of the earth's orbit, that is, if thoſe two planes were to coincide in a plane paſſing through the ſun, there would be a total eclipſe of the moon at every full, and conſequently a central eclipſe of the ſun at every change. This is improperly attributed to the ſun, becauſe it is really an eclipſe of the earth; for all the time the ſun retains his own light without the leaſt diminution, and only thoſe inhabitants of the earth that are under the ſhadow of the moon, or of the penumbra, are truly eclipſed.

But the orbs of the earth and moon, being placed obliquely, and not both in the ſame plane, interſect each other in two points, called nodes, where the moon's orbit is found to be inclined to the ecliptic in an angle of about five degrees; therefore the moon may be in ſuch a poſition from the nodes, as to paſs the oppoſition or conjunction, either too high or too low to fall into the earth's ſhadow, or to have her ſhadow or penumbra fall upon the earth. Hence it is very poſſible every full and new moon may not be eclipſed. And it will farther appear, that no eclipſe can happen but when the moon is near one of her nodes; conſequently the quantity of the eclipſe depends upon the diſtance from it: and of both kinds it may be either total, partial, or central.

Let E (*fig.* 4.) repreſent the earth, S, S, S, three different poſitions of the ſun, and M, M, M, M, M, M, various places of the moon in her orbit; let us now ſuppoſe a conjunction or an oppoſition to be made at B or C, at both which places the moon happens to be exactly in the nodes; conſequently, in either of them there will be a central eclipſe. Again, let us imagine the true ſyzigy at D or E; in both thoſe points the moon has conſiderable latitude, and can only produce a partial eclipſe. Farther, if the moon be removed to G or H, there will be no eclipſe at all. Thus, in any part of the moon's orbit, by knowing the moon's diſtance from either node, the limits of eclipſes, both ſolar and lunar, may be eaſily determined; that of the ſun will be found nearly 18°, and that of the moon 12°. Hence it is that eclipſes of the ſun, in general, are more frequent than thoſe of the moon; although in any particular place they are much fewer.

Now from the horizontal parallaxes of the ſun and moon, and their apparent ſemi-diameters, the poſſibility of a ſolar eclipſe is thus determined:

Let A *fig.* 5. repreſent the ſun, B the earth, and C the moon; then the angle HEG will be the apparent diameter of the ſun, ſeen from the earth's center; and QER the apparent diameter of the moon ſeen from the ſame place; and conſequently her ſhadow: hence, LKM will be the penumbral cone, limiting the utmoſt extent of ſuch an eclipſe, and WZ the quantity of the earth's ſurface involved in the real ſhadow at the ſame time. Now to find the apparent diameter of the penumbra in the moon's orbit, we have given the points L and M, upon the earth's ſuperficies; in which, when the moon is at C, the circles XQ and RT will repreſent the ſun's apparent diſk free from obſcuration.

To the inhabitants at L the moon's north limb will juſt touch the ſun's ſouth one, and may here repreſent the beginning of an eclipſe; when, at the ſame time, to the people at M the moon's upper limb will juſt go off the ſun's lower limb, repreſenting to them the end of an eclipſe.

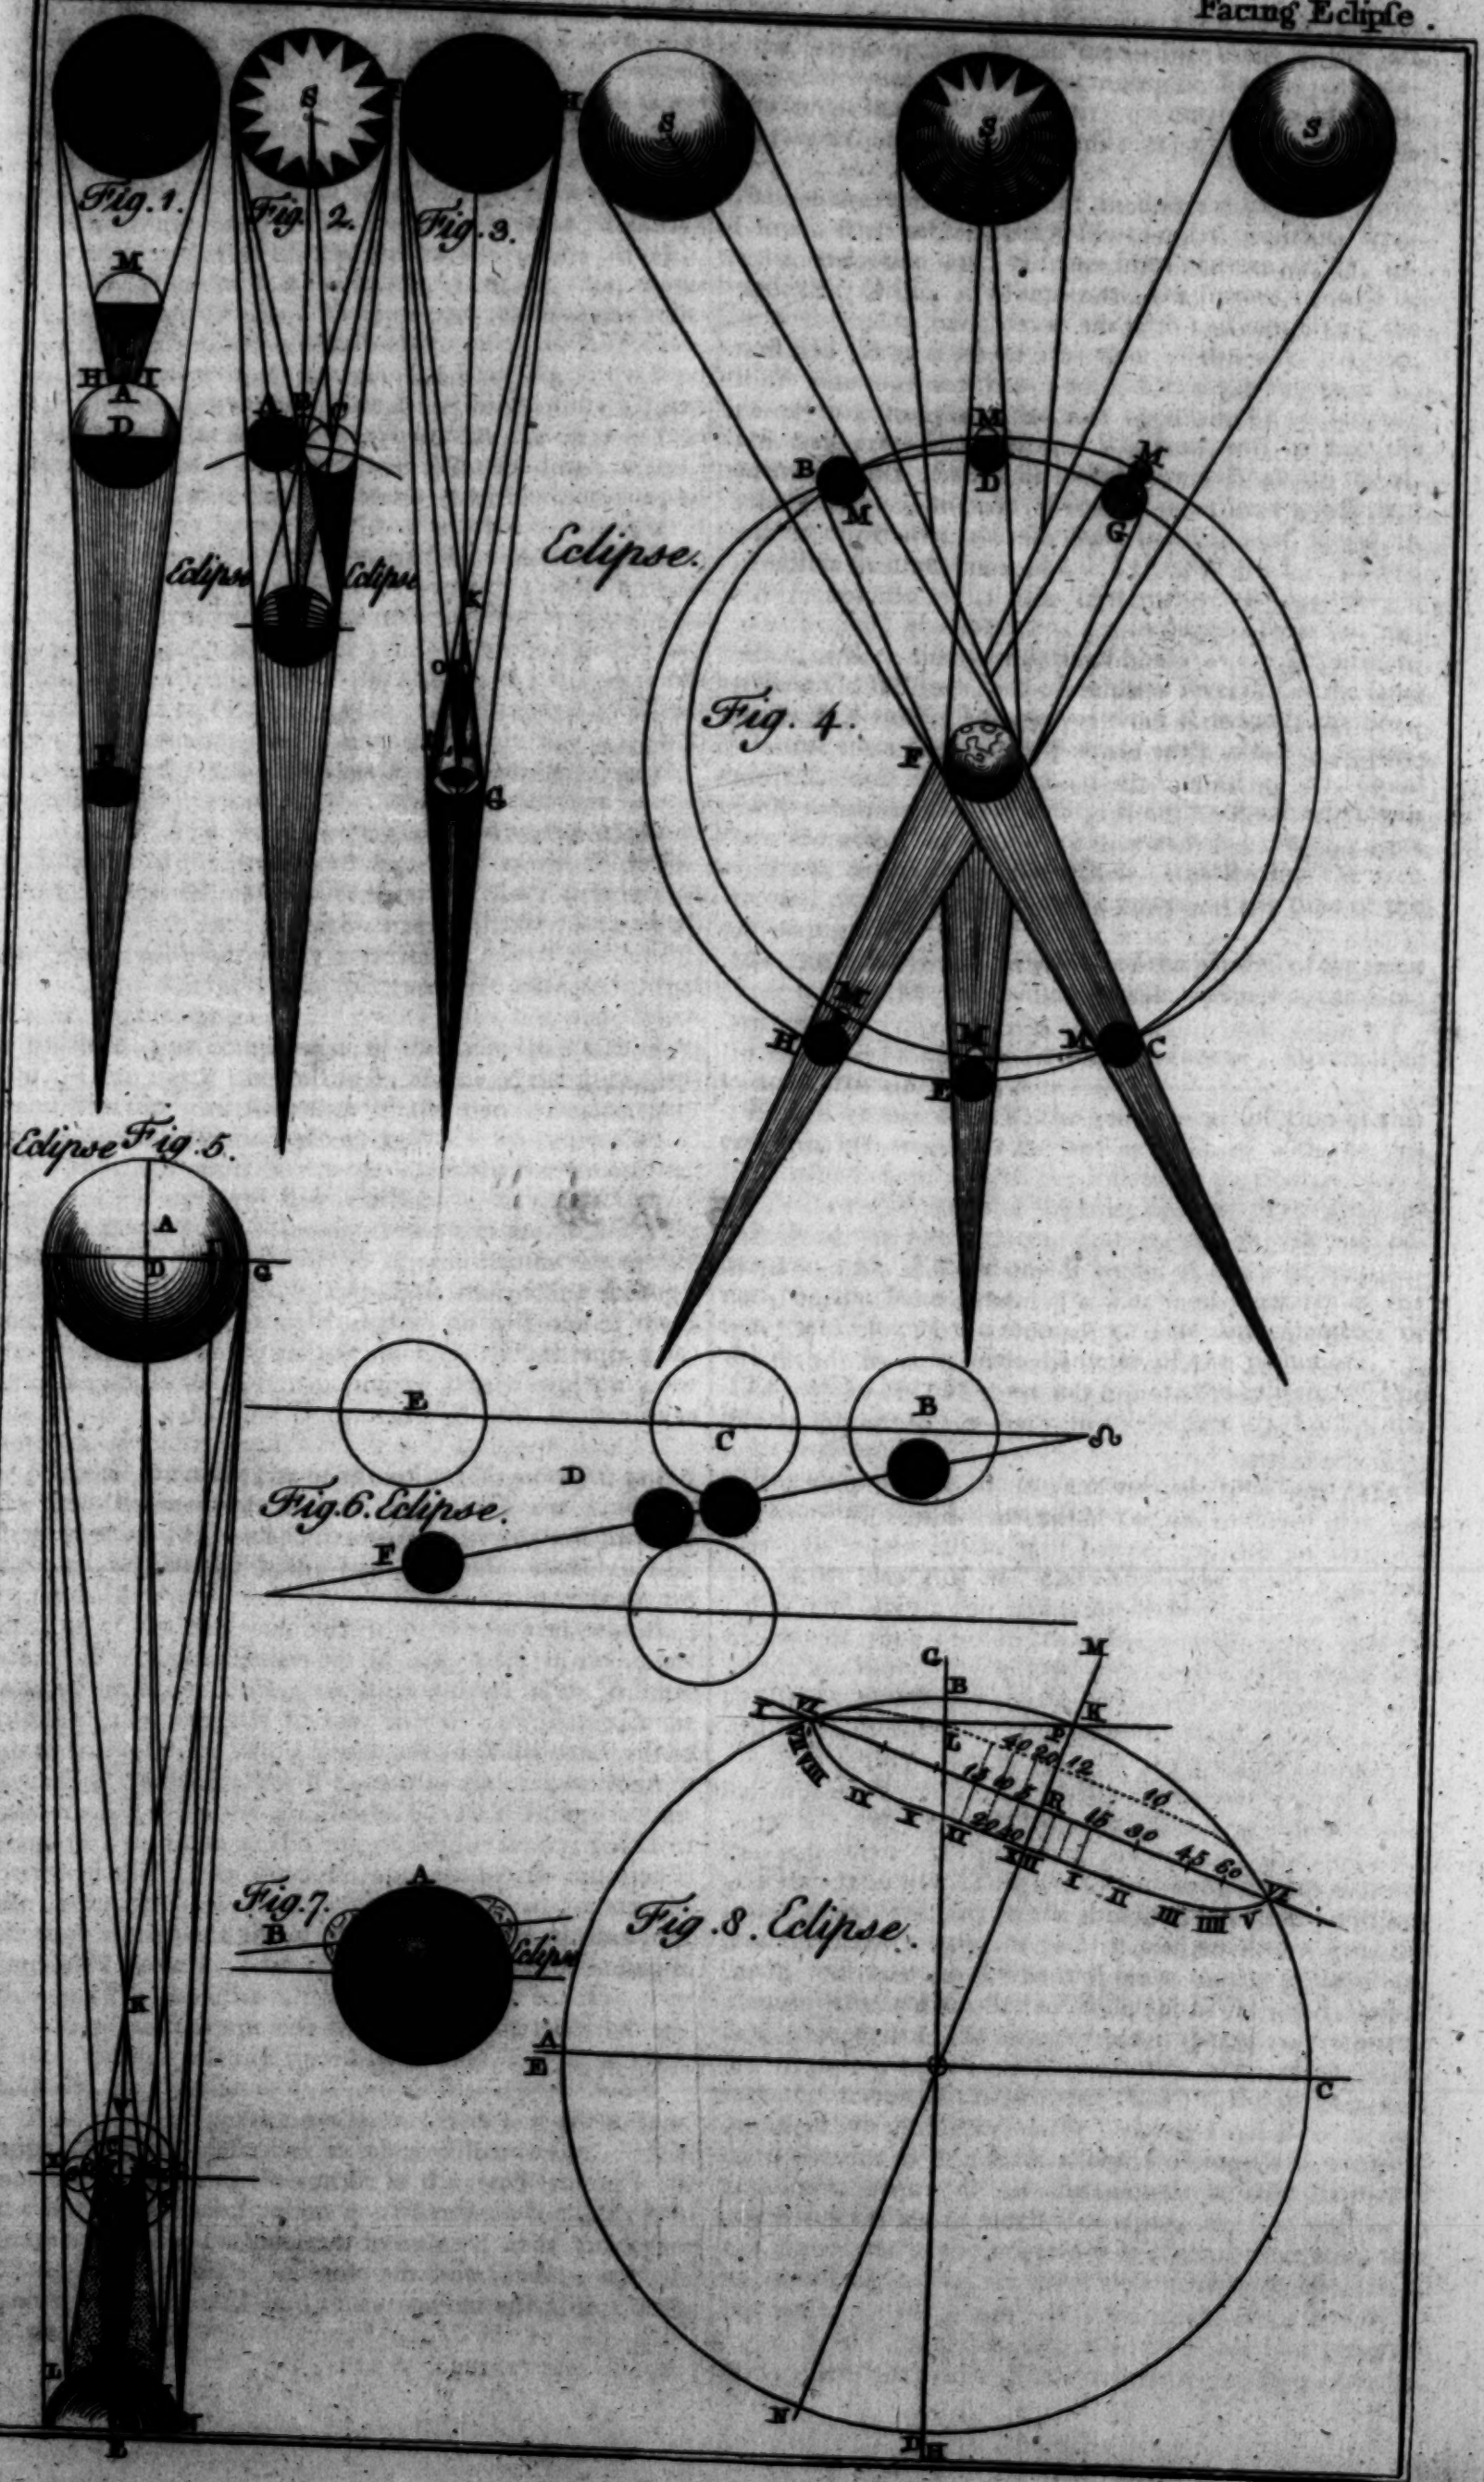
Thus it appears, that the diſtance of the two centers, S and Y, is equal to the apparent diameter of the penumbra; wherefore upon F, with the ſum of the ſemi-diameters of the ſun and moon, equal to the angle FMY, deſcribe the circle SYP, and it will repreſent the penumbra in the moon's orb.

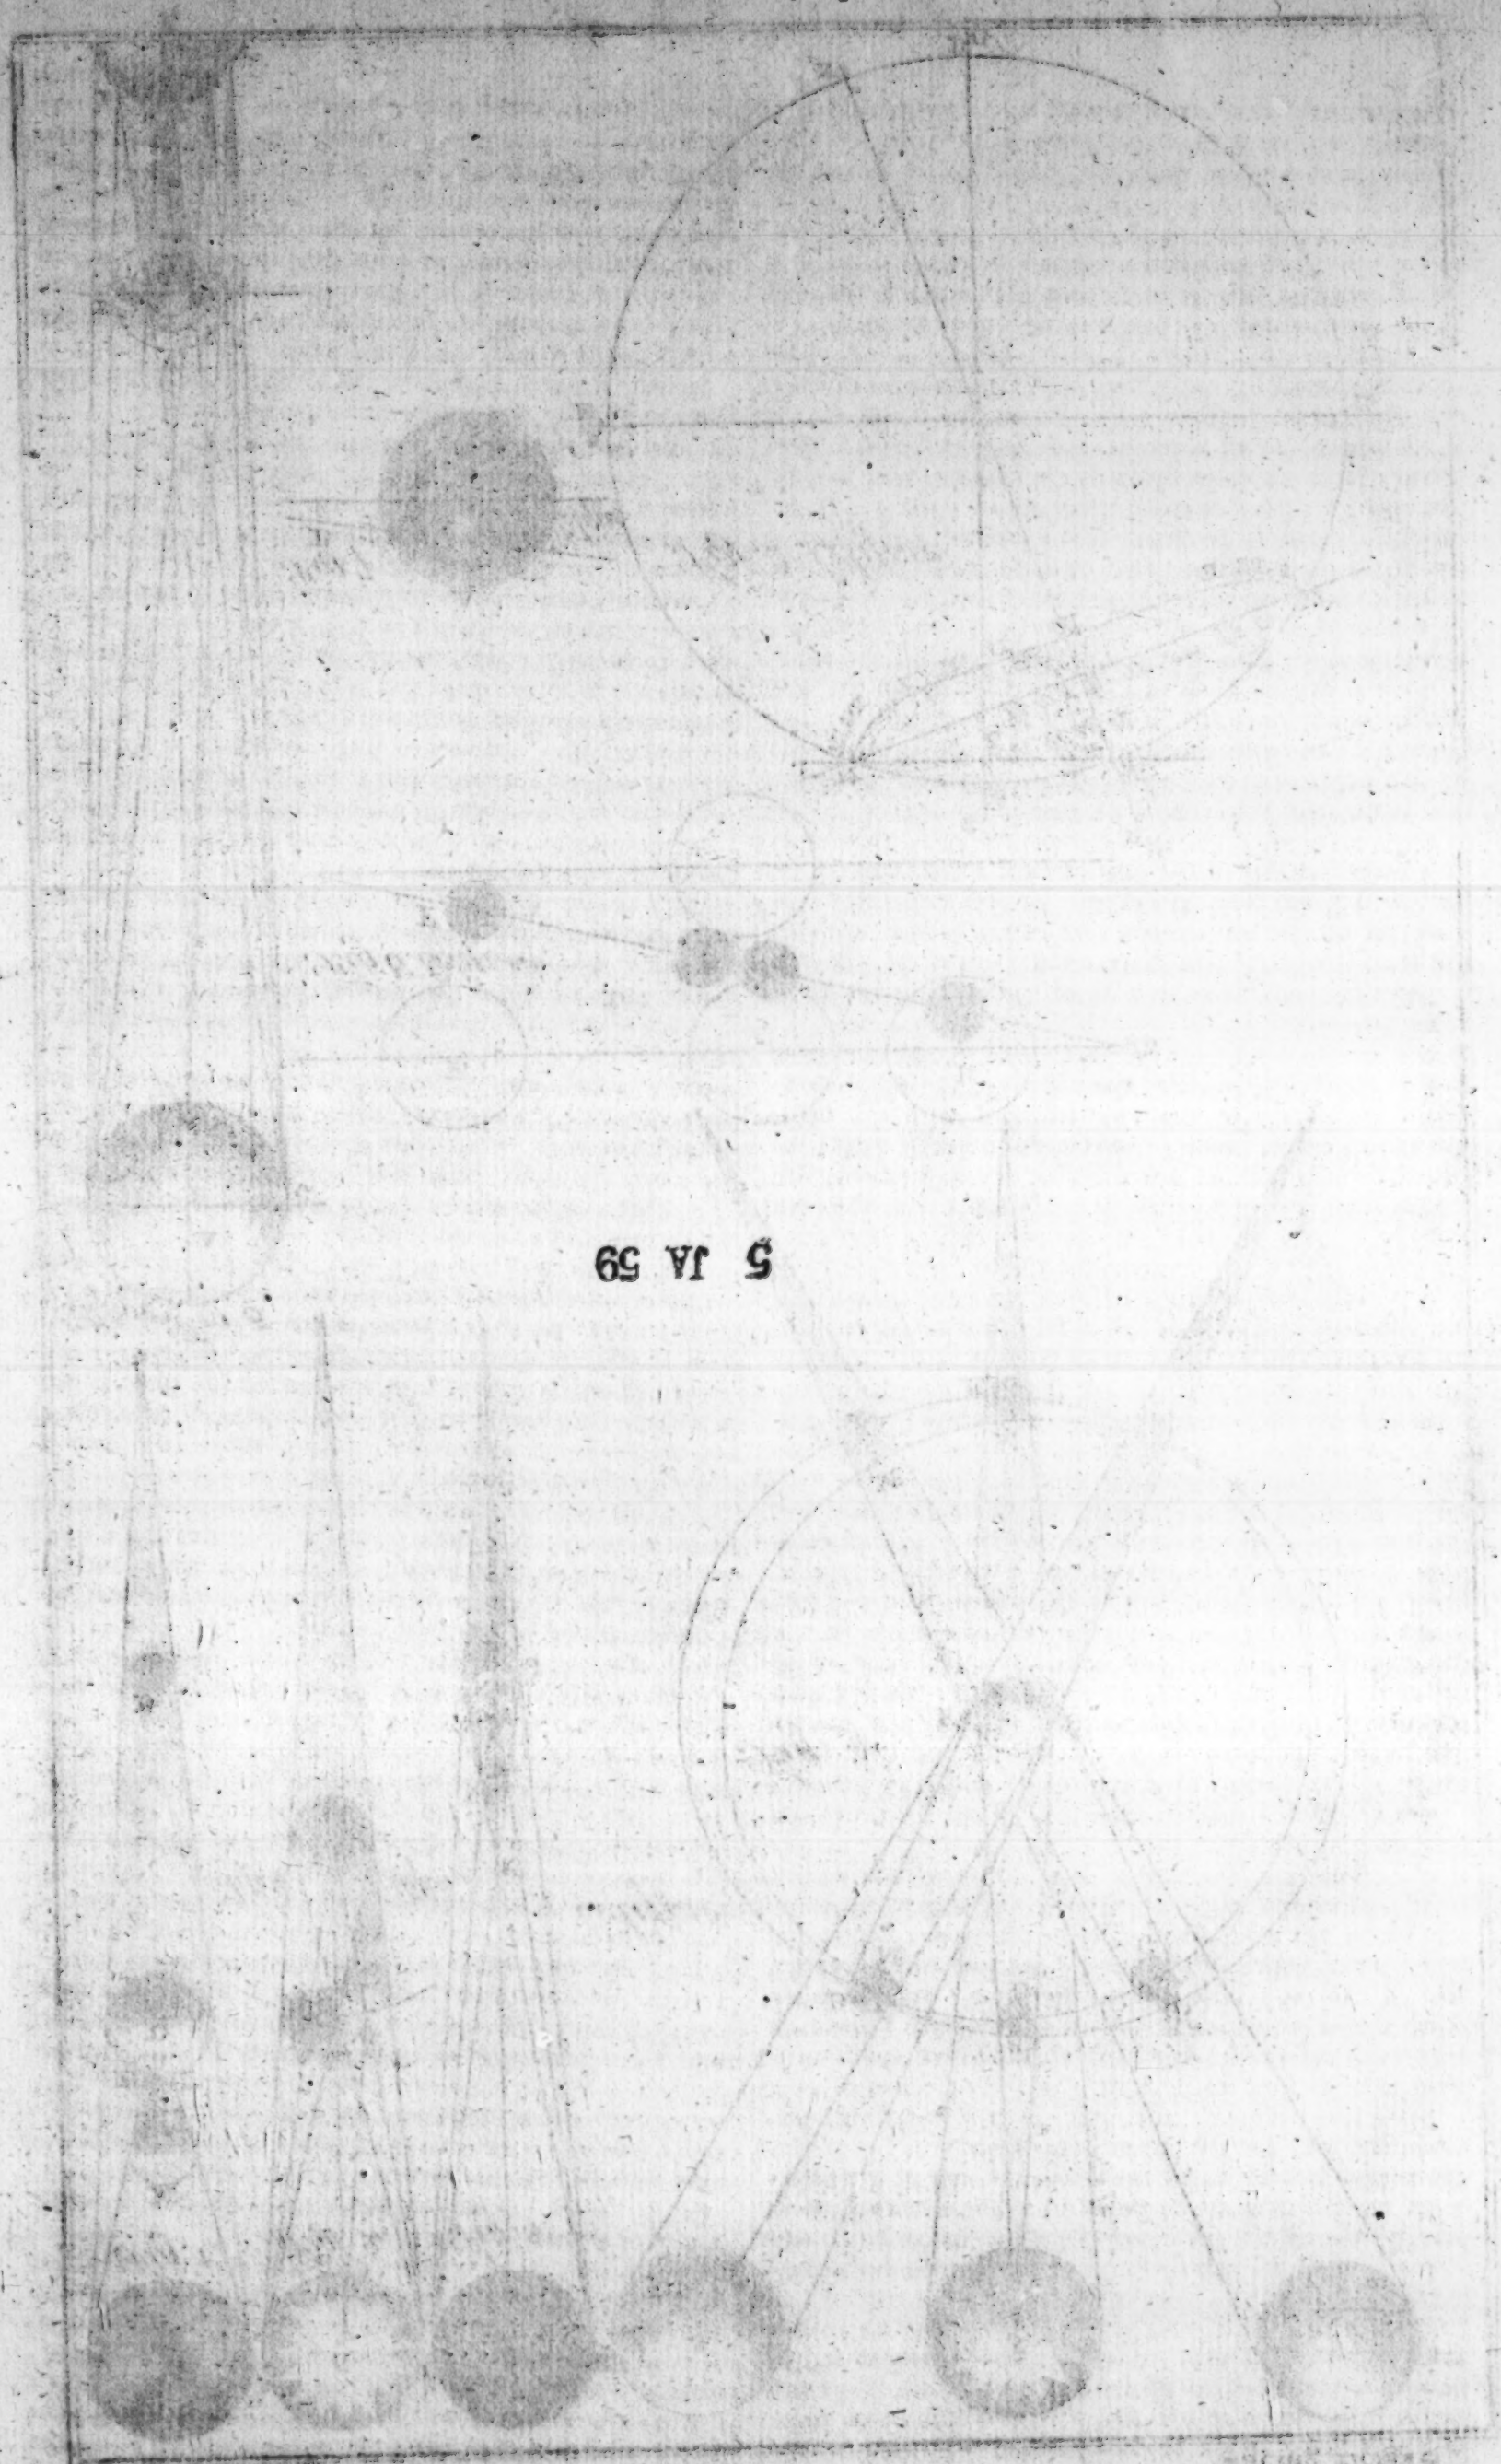
It is to be obſerved, if in the above figure C repreſents the moon perpendicular to the equator, and N the north pole, M will be the north limit, and L the ſouth limit of the ſaid eclipſe. Again, to find the apparent diameter of the earth's diſk in the moon's orb, you have given the horizontal parallax of the ſun NDE, and EFN, the horizontal parallax of the moon; draw the line IO parallel to DKE, then will the angles EDN and DNI be equal. Therefore out of the angle FNO, equal to the moon's horizontal parallax, take the angle TNO, that of the ſun, and there will remain the angle ENT equal to the apparent ſemi-diameter of the earth's diſk in the moon's orb. Hence upon the center F, with the difference of the horizontal parallaxes of the ſun and moon ENT, deſcribe XVT, and it will repreſent the ſame.

Now, as was ſaid before, if none of this penumbra fall within the ſaid diſk, there can be no eclipſe: for let E (*fig.* 6.) be the diſk in the ecliptic, and F the penumbra in the moon's orbit, F & is the diſtance of the luminaries from the node: here it is plain that the moon's latitude is greater than the ſum of the ſemi-diameters of the diſk and penumbra, and therefore no eclipſe can happen to that part of the moon's orbit: but if the ſum of the ſemi-diameters of the diſk and penumbra be greater than the moon's true latitude, as at C, then an eclipſe muſt unavoidably

PLATE LVII.

Facing Eclipse.





5 JA 59

avoidably happen to ſome place: and if the moon's latitude be leſs than the ſemi-diameter of the diſk; as at B, the eclipſe will be central, and ſomewhere may be total. And further, if all the penumbra fall within the diſk, as at A, *fig.* 7. the ſame for ſome time may be general. It is to be noted that in partial eclipſes the center of the penumbra falls without the diſk.

The geometrical conſtruction of ſolar eclipſes for particular places of the earth.

Lemma I. To an obſerver in the ſun the earth's enlightened hemiſphere would appear a ſuperficial diſk: to him the ſeveral parts of land and water would directly appear as if projected on a plane; conſequently, if circular lines, ſuch as the meridians, parallels, &c. were drawn or imagined upon it, there may be conceived an orthographical projection of the ſphere.

II. Every place upon the earth's ſurface, to the eye as above, in each diurnal revolution, apparently deſcribes an elliptical path, or otherwiſe a right line, parallel to the equator; the axis of which, at different times of the year, is variouſly inclined to the right, or to the left, from the axis of the ecliptic; that is,

III. During the ſun's progreſs through the ſummer and autumn ſigns, to wit ♋, ♌, ♍, ♎, ♏, and ♐, the axis of the earth projected on the above plane lies to the left of the axis of the zodiac; but if the ſun be in any of the other oppoſite ſigns, it will on the contrary be thrown to the right. If the ſun's place be in any of the north ſigns, that is, ♈, ♉, ♊, &c. the north pole will be enlightened; but if otherwiſe, to the ſouth, it will be obſcure.

Corollary. The conjugate diameter of every elliptical path apparently increaſes and decreaſes, as the ſun's declination doth increaſe or decreaſe. If the ſun is in the equinoctial, the path of each vertex will then be a right line, but at all other times orbicular.

It is to be obſerved, that the tranſverſe diameter of the ellipſis, repreſenting the path of any place, is always equal to twice the ſine complement of the reſpective latitude; and the conjugate one to the difference of the ſines, betwixt the ſum and difference of the two complements, latitude and the ſun's declination.

Prob. I. To repreſent the path of any vertex on the earth's diſk, as viewed from the ſun.

The general rule.—Having drawn a circle as ABCD, (plate LVII. *fig.* 8.) let it be ſuppoſed to be the earth's enlightened diſk; then, by two right lines paſſing through the center, croſs it at right angles; ſo will one of them repreſent a part of the ecliptic, as EC; the other its axis, as GH; ⊙ is the vertex point, or where the ſun is in the zenith; and B and D the ecliptic pole in the ſolar horizon.

Now, as the obliquity of the ecliptic is nearly 23° 30′, ſet this diſtance from B both ways to I and K; then draw the line IK, and ſomewhere in it you will find the elevated pole thus: Make half this line, namely, IL, equal to the radius of a line of ſines, and upon it ſet off the ſine of the ſun's diſtance from the ſolſtitial colures; which is here repreſented by the axis BD, from L, towards I or K, according to what quarter of the ecliptic the ſun is in; that is to ſay, if the ſun's longitude be given in ♑, ♒, ♓, ♈, ♉, or ♊, the ſaid diſtance will be from L towards K; but if in any of the others, from L towards I. Thus let the ſun be ſuppoſed in the beginning of Taurus, or at the end of Aquarius, the pole will be found at P; if in the former, it will be viſible; if in the latter, inviſible, being then remote and obſcure; through which, and the center of the diſk, if you draw the line MN, it will repreſent the axis of the world; and in this caſe P will be the north pole.

When the ſouth pole is elevated, it may eaſily be conceived, every plane lying in oppoſition, that the above rule will be reverſed.

Again, to delineate the ellipſis which any given place upon the earth deſcribes in twenty-four hours; if in north latitude, and the ſun be in the northern ſigns (or the latitude and declination be of the ſame kind) or if in ſouthern (or the latitude and declination be of a different kind) the difference of the ſun's declination and the pole's elevation will be the diurnal interſection, or the ſign of the ſun's meridional diſtance that day from the path of the ſaid place; and for the nocturnal interſection of the ſame, the direct contrary, that is, if their ſum be that, their difference will be this.

Thus, ſuppoſe I would repreſent the path of London in the foregoing figure, the ſun being then in the laſt ſcruple of Aries, or at the beginning of Taurus: his declination at that time will be 11° 30′ north; this added to, and ſubtracted from, the latitude 51° 32′ north, the ſum is 63° 2′, and the difference 40° 2′.

Make the ſemi-diameter of the diſk the radius of a line of ſines, from which take thoſe two laſt numbers ſeparately, and place upon the axis from the center, ⊙, towards the pole P, if illuminated, the former 12 will be the nocturnal interſection of the arch and meridian; the later XII the viſible one, or that of the day. Again, biſect that part of the axis 12 XII at right angles in R, and on this line place the ſine complement of latitude both ways from R to VI and VI, thus will be had the extreme points of each diameter, through which the ellipſis or curve is to paſs. Now to determine a ſufficient number of other points, in order to be as near the truth as poſſible in protracting the ſaid ellipſis, make R VI and R XII each the radius of a different line of ſines: then if from the firſt, you take the ſines in degrees from the meridian, of ſuch hours or parts of hours as are required to be ſhewn in the path, and place them ſeverally in the ſame tranſverſe diameter both ways, from R towards the horizon, and from the points ſo made erect as many perpendiculars, ſuch as 20, 5, 40, 40, 10, 20, 1, 15, &c. equal to the coſines of the ſaid arches, to each reſpectively taken from the other, or ſecond ſcale, you will have 24 points or hours, with other ſubdiviſions, repreſenting the true way and exact place of the ſaid vertex, at any time of the day or night.

In like manner may be projected the parallel of the ſame place at any other time, and of various places at the ſame time, &c.

Prob. II. To conſtruct the appearance of a ſolar eclipſe to any particular place, &c.

Before we can come at the geometrical ſolution of this problem, we ought to be well acquainted with the general calculation, at leaſt the following particulars.

1. The middle time of the eclipſe, or of the neareſt approach of the two centers, that is, of the disk and penumbra. 2°. The moon's latitude, at the true conjunction, at the ſame time. 3°. The ſemi-diameter of the ſun. 4. That of the moon. 5. The ſemi-diameter of the diſk. 6. The ſemi-diameter of the penumbra. 7. The inclination of the moon's orbit to the ecliptic. 8. The hourly motion of the moon from the ſun. 9. Laſtly, the ſun's declination.

For example, in the ſun's eclipſe of April 21, 1715, in the morning, the ſun in ♉ 12° 14′ 41″.

The 1		21h 42′ 18″ P. M.

Theſe requiſites being accurately known from aſtronomical tables, we may in the next place proceed to repreſent the moon's way, or path of the penumbra over the earth, and how to divide the ſame to any given place. Having deſcribed the circle ABCD (pl. LVIII. *fig.* 1.) as before, to repreſent the disk, and upon it the path of the place, &c. draw a perpendicular line to the radius of the disk, take the inclination of the moon's orb to the ecliptic, and lay it on the perimeter of the disk, as from B to E, and draw the line E ⊙; ſuch a one will repreſent the perpendicular required. If the moon's latitude be either north deſcending or ſouth aſcending, this line will lie to the right hand of the ecliptic pole; but if otherwiſe, that is, north aſcending, or ſouth deſcending, to the left of the ſame.

Again, from a ſcale in proportion to the diſk, take the moon's latitude, and place it on this line, as from ☉ to H; through H draw a line, ſuch as I K, at right angles to ☉ E, now ſuppoſed the axis of the moon's way, and it will repreſent the path of the penumbra, or the center of the general eclipſe. Now to divide the ſaid path properly to the time, at any given place; firſt, fix the time at or near the middle, according as it happens, by making proportionable allowances, as the minutes more or leſs require; then, from that point, by the hourly motion of the moon from the ſun, the motion of the whole duration may be divided into time, which, if marked reſpectively, will ſhew the place of the penumbra in its paſſage over the diſk, at every hour and minute of the ſaid continuation.

Thus, according to the hourly motions of the ☾ from the ☉, ſuppoſing the middle of an eclipſe, at London, to be 42′ paſt 9 o'clock in the morning, the path muſt be divided, &c. as in the *fig*.

As one hour of time is to the hourly motion in minutes and ſeconds of the moon from the ſun, ſo is any number of minutes in time to minutes of motion: hence, by the foregoing calculation, 60′ : 30′ 35″ :: 42′ 18″ : 25′ 6″, which, placed in the path from *a* to *b*, gives the place of the center (penumbra) at 22 hours or X of the clock.

In the above-mentioned eclipſe, proceeding as above directed, the points for 11 o'clock, and 9, by opening your compaſſes to 35′ 35″, will be found at *c* and *d*; the reſt as is repreſented in the *fig*. from which you may learn to divide, ſubdivide, and mark the ſame accordingly.

In like manner, if regard be had to the difference of meridians, any path may be divided to different places.

1. To determine the apparent time of the beginning, middle, and end of an eclipſe.

Take between your compaſſes, in proportion to that of the diſk, the ſemi-diameter of the penumbra; and, with one foot in the moon's way, moving it from the left hand towards the right, find ſuch a point, that the compaſſes ſo placed, as at *e*, the other foot may fall upon the ſame hour and minute in the path of any given vertex, as at *g*; thus will each leg point to the beginning of the eclipſe at that place.

Again, your compaſſes remaining at the ſame extent, find another point in the ſaid path, on which, if one foot be placed, the other, as before, may cut the ſame hour and minute in the path of the place, then will either point ſhew the end of the eclipſe.

To determine the requiſites at London.—From any ſcale of equal parts = 61′ 30″, the radius of the diſk, take the extent of 32′ 45″, the ſemi-diameter of the penumbra in the ſame *fig*. and that diſtance applied from one path to the other, as is taught above, you will find both pointing to 8^h 7′, the time ſought.

Likewiſe, at the end (ſee the ſame *fig*.) upon K and I, there ſhewing the hour 24′ paſt 10. Again, at M and N, the equal times in a perpendicular to the moon's way, you will find 9^h 24′, the greateſt obſcuration, or the neareſt approach of the two apparent centers (☉ and ☾), upon which, if two circles be drawn, that is, one upon M = 13′ 58″, the ſemi-diameter of the ſun; and another upon N = 16′ 46″, that of the moon, from the ſame ſcale; the latter will cut off from the former juſt ſo much as the viſible obſcuration will be.

In this manner you will find the preceding eclipſe at London will be total, and exactly 12 digits. It is to be noted, that, the air happening to be very clear when this eclipſe was obſerved, ſeveral of the planets and fixed ſtars, during the time of total darkneſs, became viſible to the naked eye.

2. To find the middle.—Apply the one ſide of a ſquare to the moon's way; ſo placed, move it backward, or forwards, until the other ſide cut equal time in each path; that is, the ſame hour and minute in one as in the other; the time ſo found will be that of the greateſt obſcuration.

3. To find the number of digits, the ſun's diameter being divided into twelve, that are eclipſed.

This is known by deſcribing two circles upon the two laſt points, which determine the middle of the eclipſe, that is, one upon the point in the path of the vertex, with the ſemi-diameter of the ſun; the other in the moon's way, with the ſemi-diameter of the moon. Thus will the quantity obſcured be ſhewn in the ſun's diameter, cut by the moon's limb.

4. How to project the viſible appearance of the eclipſe. Let M repreſent the ſun, and N the moon, at the middle of the eclipſe; draw the line ☉ M V (*fig*. 1.) as alſo M N; then will ☉ V repreſent the vertic circle, and V N M the angle of obliquity, as made by the line of connexion M N: conſequently, O being the vertic point of the ſun's limb, if the ſaid lines be reverſed, as in the above *fig*. the poſition of the viſible eclipſe, with reſpect to a perpendicular paſſing through the ſun, may be naturally ſhewn, not only at the middle, but, if required, at both the beginning and end.

In eclipſes that continue for ſome time total, or annular, if, inſtead of the ſum of the ſemi-penumbra of the ſun and moon, you make uſe of their difference, that is, if inſtead of the penumbra for total darkneſs, you make uſe of the umbra, you may eaſily find the beginning and ending of the ſame.

Prob. 3. To find at any time, and in any part upon the earth's ſurface, the ſpecies of the total ſhadow, or of the annular ſection of the penumbra.

The general rule.—Upon the center point, as at A, (*fig*. 2.) deſcribe a circle equal to the difference betwixt the apparent diameter of the ſun and moon; this circle ſhall project upon the globe the true quantity of the ſaid ſhadow or penumbral ſection; therefore, if you take the dimenſion of it from a ſcale of ſines, in proportion to the radius of the diſk, and transfer it upon a plane, you will have the true poſition, figure, and direction, upon the earth; which in all parts of the world, but where the ſun is vertical, will be an ellipſis, and more or leſs irregular, according to its diſtance from the ſolar horizon. The direction of the middle, it is to be noted, is various, according to the ſeaſon of the year and time of the day.

The obliquity of the figure entirely depends upon the ſun's altitude; and, in eclipſes that happen near the horizon, is very much diſtorted during its ſtay on the illuminated hemiſphere; upon every different country it is continually changing its ſhape, and putting on a new form, ſuch as A, B, or C (*fig*. 3.)

It is to be noted, that the ſection of every cone, &c. made by a ſpherical ſurface, is not eaſily determined any other way but by conſtruction; in the vaſt penumbra it is beſt underſtood by throwing a diſtinct ſhadow upon a round ball or globe.

The longer or tranverſe diameter always coincides with the line of the ſun's azimuth; the conjugate is at right angles with it.

Let E (*fig* 2.) be the earth's diſk, A the moon's center in the line of her paſſage over it, N O, and the circle B C D E, the ſpace or portion of the earth's ſurface to be delineated. Draw the diameter G A H, and at right angles to this the line I K paſſing through the center of the penumbra; alſo a perpendicular to the path, as L M. Now, if to theſe be drawn other lines parallel, ſuch as *a b*, *c d*, *e f*, *g h*, *i k*, *l m*, *n o*, and *p q*, equal to the radius A B; then will *a* N *c*, *f* M *h*, and *i m*, be the true dimenſions of the ſaid ſhadow or penumbra, in all its parts from the center; that is, *i m* will be the ſhorteſt diameter, and *o q* the longeſt; *a c* will be the perpendicular breadth, and *f h* the obliquity; which, if meaſured in degrees, and reduced into geographical miles, you may eaſily know both its limits and direction.

That narrow compaſs, called the umbra, or the ſmall annular ſpace of the penumbra, approaches nearly to a plane, being the ſection of a cone cut by a ſpherical ſurface: whence it will appear (Eu. lib. iii. p. 6.) that the center of the baſe of the cone is not the real center of the eclipſe.

Scholia. The duration of total darkneſs, and conſequently the extent of the umbra, penumbra, or entire eclipſe to different places, along or near the path of the moon's center, is vaſtly various upon account of the un-

equal elevation of the luminaries above the horizon: for the moon is much nearer to a ſpectator upon the earth, when ſhe is in the meridian, than when ſhe is riſing or ſetting; and when ſhe is in the zenith of any place, ſhe is nearer by a ſixtieth part of her diſtance from us, than when ſhe is in the rational horizon; and, in conjunctions which happen near the zenith, this is therefore conſiderable, for which a particular allowance muſt be made.

The duration of a ſolar eclipſe, in any particular place, is more or leſs, according as it happens nearer to or farther from noon; by reaſon that, near ſix o'clock, the diurnal motion conſpires with the ecliptic one leſs than at 12 o'clock at noon. The velocity of the ſhadow is very unequal, ariſing not only from the inequality of the moon's proper motion, but alſo from the oblique variation of every horizon; but as the latitude and the longitude of any point, in its direction, may be eaſily known, there can be no great difficulty in finding it.

Of the general Tranſit of an ECLIPSE, &c. and how to find the time and particular place of the beginning, &c. of the general eclipſe.

Let BRCN (*fig.* 4.) repreſent the earth's diſk in the ecliptic, BC and FK, &c. the moon's way or paſſage of the penumbra over it, P the north pole. Now the time when the moon's center will be at FDIHME and R is required. In the firſt place, here is given FO = KO, the ſum of the ſemi-diameters of the diſk and penumbra; ſecondly, DO = OE, the ſemi-diameter of the diſk; and laſtly, MO, the neareſt approach of the luminaries to the center of the diſk, to find FOH and DOH, the two angles of incidence. By the ſolution of a right angled triangle, having found the reduction MH, ſay, As OP or DO is to the radius, ſo is HO to the ſine complement of the angle HOF or DOH: then to find the ſemi-duration FH or HK, the analogy is, As the radius is to FO; ſo is the angle of incidence FOH to FH: or by Eucl. i. 47. $FH = \sqrt{FO^2 - HO^2}$. In like manner may be found DH = HE; which, if divided by the hourly motion of the moon from the ſun, will give each reſpective arch in time; this added to, or ſubtracted from, the time of the greateſt obſcuration, will give the beginning and ending of the general eclipſe, &c.

Now, to find the latitude and longitude of thoſe places upon the earth, over which the center of the penumbra paſſes, O will be that place to which the ſun is vertical; its latitude is always equal to the ſun's declination; and its longitude, from the place to which the tables are accommodated, is equal to the time from noon in that place reduced into degrees and minutes: hence the poſition of the center is known; and conſequently, by the doctrine of ſpherics, the latitude and longitude of any given point, ſuch as G, D, I, H, M, E, or L, may be found. G is the place where the ſhadow firſt touched the earth; D the place where the center firſt comes on, I the point where the ſun is eclipſed in the univerſal meridian; H the place where the center falls; M the nonageſimal degree; E the place where the center goes off from the earth; L the place where the penumbra leaves it.

The mean velocity of the ſhadow over the earth is always equal to the hourly motion of the moon from the ſun in the moon's orbit, reduced into geographical miles.

Lunar ECLIPSES are occaſioned by the interpoſition of the earth betwixt the ſun and the moon, whereby the moon is deprived of her luſtre by falling into the earth's ſhadow; and for the ſame reaſon as to quantity and duration, is both general and univerſal. A lunar eclipſe can never happen but at the full, and when the moon is leſs than half a ſign from one of the nodes. Now the moon, although deprived of the direct ſolar beams, is not abſolutely hid from us at the ſame time, as at the change; becauſe the rays of light paſſing through our atmoſphere are refracted, and thrown obliquely into the real ſhadow, and thereby faintly illuminate the whole cone: hence it is that the moon's body remains viſible to us, though it be totally eclipſed.

The beginning and ending, &c. of a lunar eclipſe are found in the ſame manner by the angles of incidence, &c. as has been before ſhewn of the ſun's eclipſe, only with this difference, that, whereas in the latter it is underſtood of the diſk and penumbra, here the ſame is to be underſtood of the moon and the earth's ſhadow.

To find when there will be an eclipſe of the moon, and when not.—Let AE (*fig.* 5.) repreſent the path of the earth's ſhadow at the diſtance of the moon near the node ☊, and FH a part of the lunar orbit, and the ſection of the earth's ſhadow be delineated at ☊, B, C, D, and the full moon at ☊, I, N, G; then it is evident, where the leaſt diſtance of the centers of the moon and ſhadow exceeds the ſum of their ſemi-diameter, there can be no eclipſe of the moon, as at D; but, where that diſtance is leſs, the moon muſt be partly or wholly involved in the ſhadow, and ſo ſuffer an eclipſe, as at B and ☊; in which latter caſe the moon paſſes over the diameter of the ſhadow.

But in a certain poſition of the ſhadow, as at C, the leaſt diſtance of the centers NC is equal to the ſum of the ſemi-diameters; and therefore ☊C is the ecliptic limit for lunar eclipſes: to find which we have NC = 63′ 12″ nearly when greateſt, and the angle N☊C = 5° 00′. Therefore, as the ſine of the angle N☊C, is to radius; ſo is the ſide NC, to the ſide ☊C = 725′ 2″ = 12° 5′. Hence, if the moon be at a leſs diſtance from the node ☊ than 12° 5′, there will be an eclipſe, otherwiſe none can happen.

ECLIPTIC, in aſtronomy, is that circle which the plane of the earth's orbit would mark out, were it ſuppoſed to be extended to the heavens. This therefore is that which the ſun ſeems to deſcribe in his annual courſe.

The axis of the ecliptic is a right line ſuppoſed to paſs through the center of the ſun, and to be perpendicular to the plane of the ecliptic; and the points in the heavens, to which this axis is directed, are called its poles; and the great circles paſſing through theſe poles will be perpendicular to the ecliptic, and therefore called its ſecondaries, and ſometimes circles of longitude.

By means of theſe the place of any ſtar is referred to the ecliptic, and its longitude and latitude eſtimated: for the longitude of a ſtar is an arch of the ecliptic intercepted between the firſt point of Aries, and that where one of theſe ſecondaries that paſſes through the ſtar cuts the ecliptic; and the latitude of a ſtar is the arch of the ſame ſecondary intercepted between the ſtar and the ecliptic. Upon this account all circles conceived to be drawn parallel to the ecliptic, that is, parallels of the ecliptic, are ſometimes called parallels of latitude. The latitude of a ſtar is either northern or ſouthern, as the ſtar is placed on this or that ſide of the ecliptic.

The ecliptic is divided into twelve parts, called ſigns. They begin at that point in which the ſun appears to be at the vernal equinox, and are reckoned from weſt to eaſt. The names of the ſaid ſigns, together with the characters whereby they are commonly expreſſed, are theſe that follow.

Aries.	Taurus.	Gemini.	Cancer.	Leo.	Virgo.
♈	♉	♊	♋	♌	♍
Libra.	Scorpio.	Sagittarius.	Capricornus.	Aquarius.	Piſces.
♎	♏	♐	♑	♒	♓

The firſt ſix of theſe are called the northern ſigns, as poſſeſſing that half of the ecliptic which lies neareſt the north pole of the earth; the latter, the ſouthern, as being in that which is neareſt the ſouth pole. The ſun is always ſeen in ſome part of this circle; but the planets, by reaſon of the inclination of the plane of their orbits to that of the ecliptic, appear ſometimes above it, and ſometimes below it, but never deviate from it above 7 or 8 degrees on either ſide: ſo that if we imagine a ſpace ſurrounding the heavens 16 degrees in breadth, and extended equally above and below the ecliptic, this will include all their ecliptics, ſo to ſpeak; that is, all the circles they would appear to move in when ſeen from the ſun, and is called the zodiac.

The ſigns of the ecliptic took their names from 12 conſtellations ſituated in the heavens near thoſe places. But it muſt be remembered, that the ſigns are different from the conſtellations which bear the ſame name: for the ſign Aries is not, for inſtance, in the ſame part of the heavens with the conſtellation Aries; the former is only

30 degrees of the ecliptic, counted from one of the equinoctial points; whereas the conſtellation is a ſyſtem of ſtars, the moſt of which are now ſituated between the firſt and laſt degree of Taurus: and ſo of the other ſigns. Theſe conſtellations were, in the infancy of aſtronomy, ſituated within the ſigns which now bear their names: but, by a ſlow retrograde motion of the equinoctial points, called the preceſſion of the equinoxes, the conſtellation Aries has got into the ſign Taurus, and that of Piſces into the ſign Aries; and ſo of the reſt.

It has been a ſubject of controverſy amongſt aſtronomers, whether the obliquity of the ecliptic be variable or not; that is, whether the angle between the planes of the ecliptic and equator, continues always unchangeably the ſame, or is ſubject to alteration: it is alſo diſputed among theſe writers who hold it liable to change, whether that change be regular or irregular. It is certain that the obliquity of the ecliptic is at preſent found to be above a third part of a degree leſs than Ptolemy has given it us. From Ptolemy's time down to Tycho, ſome obſervations have made it leſs, and others more, by a few minutes. They who will have the obliquity to have been always the ſame as it is at preſent, ſurmount all theſe difficulties, by throwing upon the inaccuracy of the obſervations of the ancients, and the imperfection of their inſtruments, all the differences found between them and the moderns: others think this is treating the ancients with too little reſpect; for though it appears by Ptolemy, that they did not pretend to obſerve more nicely than to a ſixth part of a degree, and their inſtruments fell far ſhort of thoſe made uſe of by the moderns; yet it can hardly be imagined they could be ſo greatly miſtaken in a matter ſo eaſy to be known, and ſo well deſerving their attention. As for thoſe who ſuppoſe that the obliquity is ſubject to a ſort of libration, increaſing in ſome ages, and decreaſing in others, they attribute a greater degree of exactneſs to the obſervations on which they ground this fancy, than they ought. Some have imagined that the obliquity has been always gradually decreaſing, the planes of the ecliptic and equator growing continually nearer to a coincidence. This opinion, beſides its being founded upon a compariſon of ancient and modern obſervations, receives a good deal of ſupport from the conſideration of the figure of the earth.

The obliquity of the ecliptic is equal to the diſtance of either tropic from the equator; the beſt way of finding it, becauſe leaſt liable to error from refraction, is to take the ſun's height when in the ſummer tropic, the height of the pole, and conſequently its complement, the height of the equator, being firſt known in the place of obſervation. There is another way of finding this, the only one made uſe of by the ancients, namely, to obſerve the ſun's meridian height in each tropic; but then refraction muſt be taken into the account, which increaſes the ſun's meridian altitude, when he is low in the winter ſolſtice, more than when he is high in the ſummer: ſo that the tropics are brought nearer to one another by refraction. For want of being aware of this, the ancients meaſured the diſtance of the tropics leſs than it really was: they all ſuppoſed the ſun's parallax too great, which in like manner diminiſhed the diſtance between the tropics, and that about twice as much as they leſſened it by not conſidering refraction. Theſe errors are no hinderance to our making uſe of their obſervations in this diſquiſition; becauſe we know what allowance to make for the conſequences they draw after them. Now, after proper allowances, the obliquity of the ecliptic comes out from the obſervations of the ancients above a third part of a degree greater than the modern aſtronomers have found it. Louville, after comparing all the ancient obſervations, was of opinion, that the obliquity of the ecliptic decreaſed at the rate of 1′ in a hundred years, and, from a great number of obſervations of his own about the year 1711, ſet it down 23° 28′ ½, which is ½ a minute leſs than Flamſtead and De la Hire made it: he goes farther, and thinks he diſcovered it to be five ſeconds leſs in the year 1720, than he obſerved it in 1714. But, notwithſtanding the great care with which his obſervations appear to have been made, ſuch a degree of exactneſs, as is here pretended, is hardly credible.

A TABLE of the OBLIQUITY of the ECLIPTIC.

	Authors Names.	Yrs. before Chriſt.	Obliquity.

The letter F on the ſide of the tables intimates the obſervation to be taken from Flamſtead; R from Ricciolus's Almageſt; L from Louville; and thoſe without a letter are from the authors themſelves.

If there be any change in the obliquity of the ecliptic, which it is very probable, it may be cauſed either 1. by a change in the inclination of the earth's axis, the plane of the earth's orbit continuing immoveable; or, 2. by a change in the plane of the earth's orbit, the axis of the earth continuing parallel to itſelf; or, 3. by a change both in the inclination of the axis and in the ſituation of the earth's orbit. The firſt of theſe ſeems moſt likely to be the caſe; for if we conſider the ſhape of the earth, that it is an oblate ſpheroid, or a globe a little flatted like a turnep, having its diameter at the poles a little ſhorter than at the equator; and that, by reaſon of this figure of the earth, the attraction of the heavenly bodies will act upon it in the ſame manner as if it had a ring round the equator; and that the ſun, being in the plane of the ecliptic, is perpetually pulling this ring, or the protuberant parts about the equator of the earth, towards a coincidence with the plane of the ecliptic; which action of the ſun, together with the like attraction of the moon, is the cauſe of the preceſſion of the equinoxes; and if this be conſidered, it will not appear improbable, that theſe actions of the ſun and moon, which have a continual tendency to bring the plane of the earth's equator nearer to the plane of the ecliptic, ſhould gradually diminiſh the angle between theſe planes. The moon indeed, being nearer to the earth, contributes more than the ſun towards this effect, by her attraction; for though ſhe be but twice a month in the ecliptic, yet ſince ſhe is always near it, never deviating much above five degrees from that circle; and theſe deviations are as much towards the north in one half of her period round the earth as they are towards the ſouth in the other; they will ſo balance one another, that the effect of the whole attraction of the moon will be pretty much the ſame, as if ſhe were carried round the earth exactly in the plane of the ecliptic.

However,

However, all changes in the poſition of the ecliptic are not to be abſolutely excluded; for, as the planets move round the ſun in different planes, their mutual attractions muſt have a tendency to change the ſituation of all their planes, and bring them nearer to a coincidence with one another: but then the diſtance of the planets from each other is ſo great, that the change here mentioned may be ſo exceedingly ſmall as not to become ſenſible in many ages.

ECLOGUE, in poetry, a little elegant compoſition in a ſimple natural ſtyle.

The word is derived from the Greek, ἐκλέγω, to ſelect.

The eclogue, in its primary intention, is the ſame thing with the idyllium; but cuſtom has likewiſe made ſome difference between them, and appropriated the name eclogue to pieces wherein ſhepherds are introduced; and idyllium to thoſe written like eclogues, but without any ſhepherds in them.

The eclogue then is properly an image of the paſtoral life; therefore the matter is low, and its genius humble. Its buſineſs is to deſcribe the loves, ſports, piques, jealouſies, intrigues, and other adventures of ſhepherds; ſo that its character muſt be ſimple, the wit eaſy, and the expreſſion familiar. The true character then of the eclogue is ſimplicity and modeſty: its figures are neat, the paſſions tender, the motions eaſy; and though ſometimes it may have little tranſports and deſpairs, yet it never riſes ſo high as to be fierce or violent. Its narrations are ſhort, deſcriptions little, the thoughts ingenious, the manners innocent, the language pure, the verſe flowing, the expreſſions plain, and all the diſcourſe natural.

The models in this ſort of poetry are Theocritus and Virgil, who both have ſome eclogues of a lofty character: the eclogue, therefore, occaſionally raiſes its voice. Yet M. Fontenelle eſteems it a fault in ſome modern poets to have put matter of high concern in their eclogues, and made their ſhepherds ſing the praiſes of kings and heroes.

Some imagine the name eclogue to have been originally applied to ſuch poems as were written in imitation of others; ſuch are the eclogues of Virgil, which are only imitations of Theocritus.

ECLOGUE is alſo applied to certain compoſitions in proſe: ſuch are thoſe of Strabo, Diodorus, &c. in which ſenſe the word ſignifies only an extract, or collection.

ECOUTE, in the manege, a pace or motion of a horſe, when he rides well upon the hands and the heels, is compactly put upon his haunches, and hears or liſtens to the heels or ſpurs, and continues duly ballanced between the heels, without throwing to either ſide. This happens when a horſe has a fine ſenſe of the aids of the hand and heel.

ECPHORA, in architecture, commonly ſignifies the diſtance between the extremity of a member or moulding, and the naked of the column, or any other part it projects from. Some authors, however, account for the ecphora from the axis of the column, and define it to be the right line intercepted between the axis and the outermoſt ſurface of a member or moulding.

ECPHRACTICS, in medicine, remedies which attenuate and remove obſtructions.

ECPIESMA, in ſurgery, a ſort of fracture of the cranium, when the bones are much ſhattered, and, preſſing inwardly, affect the membranes of the brain.

ECPIESMA, in pharmacy, ſignifies the maſs remaining after the juices of vegetables have been preſſed out; and, in this ſenſe, is the ſame as magna. It ſometimes further imports the juice preſſed out.

ECTASIS, in grammar, the ſame with diaſtole. See the article DIASTOLE.

ECTHESIS, in church hiſtory, a confeſſion of faith, in the form of an edict, publiſhed in the year 639, by the emperor Heraclius, with a view to pacify the troubles occaſioned by the Eutychian hereſy in the Eaſtern church.

ECTHLIPSIS, ἐκθλῖψις, among Latin grammarians, a figure of proſody, whereby the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the ſake of the meaſure of the verſe: thus they read *mult' ille*, for *multum ille*.

ECTROPIUM, in ſurgery, is an inverſion of the eye-lids, when they are ſo retracted that their interior red ſkin becomes prominent, and the eye cannot be ſufficiently covered by them.

The word is derived from the Greek, ἐκτρέπω, to invert.

ECTYLOTICS, in pharmacy, remedies proper for conſuming calloſities. See the article CALLUS.

ECTYPE, in antiquity, is an impreſſion of a medal, ſeal, or ring; or a figured copy of an inſcription, or other ancient monument.

The word is derived from the Greek, ἐκ and τύπος, reſemblance; becauſe it reſembles the original.

ECU, or ESCU, a French crown; for the value of which ſee the article EXCHANGE.

ECUSSON, in heraldry, a little eſcutcheon.

EDDISH, or EADISH, the latter paſture or graſs that comes after mowing, or reaping; otherwiſe called eagraſs, earſh, and etch.

EDGINGS, in gardening, the ſeries of ſmall, but durable, plants, ſet round the edges or borders of flower-beds, &c. The beſt and moſt durable of all plants for this uſe is box, which, if well planted, and rightly managed, will continue in ſtrength and beauty for many years. The ſeaſons for planting this are the autumn, and very early in the ſpring: and the beſt ſpecies for this purpoſe is the dwarf Dutch box. The edgings of box are now only planted on the ſides of borders, next walls, and not, as was ſome time ſince the faſhion, all round borders or fruit beds, in the middle of gardens, unleſs they have a gravel walk between them, in which caſe it ſerves to keep the earth of the borders from waſhing down on the walks in hard rains, and fouling the gravel.

In the laſt age it was alſo a very common practice to plant borders, or edgings, of aromatic herbs, as thyme, ſavory, hyſſop, lavender, and the like: but theſe are all apt to grow woody, and to be in part, or wholly deſtroyed in hard winters. Daiſies, thrift, or ſea july-flower, and chamomile, are alſo uſed by ſome for this purpoſe; but they require yearly tranſplanting, and a great deal of trouble, elſe they grow out of form; and theſe are alſo ſubject to periſh in very hard ſeaſons.

EDHELING, *Edhelingus*, the ſame with Atheling. See the article ATHELING.

EDICT, *Edictum*, in matters of polity, an order or inſtrument, ſigned and ſealed by a prince, to ſerve as a law to his ſubjects.

EDIFICE, the ſame with building. See BUILDING.

EDILE, or ÆDILE. See ÆDILE.

EDINBURGH, the capital city of Scotland, ſituated about one mile ſouth of Leith, and of the Firth of Forth, eighty-two miles north-weſt of Newcaſtle, and about three hundred north-weſt of London: weſt long. three degrees, and fifty-ſix north lat.

Here the parliament of that ancient kingdom uſed to aſſemble, before its union with England; and here the ſupreme courts of juſtice for North-Britain are ſtill held. It has likewiſe a celebrated univerſity, and exceeds all the cities of the world for the loftineſs of its buildings, which are all of hewn ſtone, faſhed, and ten, eleven, or more ſtories high: it is alſo remarkable for the ſpaciouſneſs of its High-ſtreet, its Caſtle, the palace of Holyrood-houſe, &c.

EDITOR, a perſon of learning, who has the care of an impreſſion of any work, particularly that of an ancient author.

EDUCATION is the bringing up and forming the minds of children, either in point of learning or good manners.

The word is formed from the Latin, *educo*, to bring up.

EDULCORATION, in pharmacy, the ſame with dulciſying. See the article DULCIFYING.

EDULCORATION, in chemiſtry, is the ſweetening or clearing of any matter from impurities, eſpecially the ſalts it may be impregnated with, by waſhing it thoroughly in common water; ſo that it is the ſame with ablution.

The word is derived from the Latin *edulcoro*, to ſweeten, and that from *dulcis*, ſweet.

EEL, *Anguilla*, in ichthyology, a ſpecies of muræna. See the article MURÆNA.

EEL-BACKED, an appellation given to ſuch horſes as have black liſts along their back.

EEL-SPEAR, a forked inſtrument with three or four jagged teeth, uſed for catching of eels: that with the four teeth is beſt, which they ſtrike into the mud at the bottom of the river, and if it ſtrike againſt any eels, it never fails to bring them up.

EFFECT is that which reſults from, or is produced by, any cauſe. See CAUSE.

EFFECTIONS, in geometry, are uſed in the ſame ſenſe with the geometrical conſtruction of propoſitions, and often of problems and practices, which, when they are deducible from, or founded upon, ſome general propoſition, are called the geometrical effections thereunto belonging.

EFFERVESCENCE, in a general ſenſe, ſignifies a ſlight degree of ebullition in liquors expoſed to a due degree of heat. But the chemiſts apply it to that ebullition which is excited when two ſubſtances of different natures, an alcali, for example, and an acid, are mixed together. If the efferveſcence produces a heat in the ſubſtance ſo mixed, it is called a hot efferveſcence; but, if no heat is excited, it is a cold efferveſcence.

The chemiſts formerly confounded efferveſcence with fermentation; but the learned Boerhaave has very judiciouſly limited the ſignification of fermentation to that inteſtine motion of vegetable juices, which produces either a vinous ſpirit or vinegar; and calls all other ebullitions, produced by the mixture of bodies, efferveſcences.

The word is derived from the Latin, *effervco*, to boil over.

EFFICACIOUS, a term uſed by divines, in ſpeaking of grace; importing ſuch grace, as never fails to produce its effect. See GRACE.

EFFLORESCENCE, among phyſicians, the ſame with exanthema. See the article EXANTHEMA.

EFFLUENT FEVER, the ſame with an inflammatory one. See the article INFLAMMATORY.

EFFLUVIA, minute particles which exhale from bodies.

The word is derived from the Latin *ex*, from, and *fluo*, to flow.

EFFUSION, in a general ſenſe, the pouring out of any thing liquid, and that with ſome violence.

EFT, in zoology, the Engliſh name of the common lizard, *lacertus vulgaris*, called alſo, in ſeveral parts of the kingdom, the newt and ſwift. See the article LIZARD.

EGG, *Ovum*, in natural hiſtory, a body formed in certain females, in which is contained an embryo, or fœtus, of the ſame ſpecies, under a cortical ſurface or ſhell.

An egg conſiſts of the albumen or white, and of the vitellus or yolk. The albumen is a cold, viſcous, white liquor in the egg, differing in conſiſtence in its different parts. Dr. Harvey not only obſerved this difference, but alſo that there are two diſtinct albumens, both of which are involved in their proper membranes: of theſe one is very thin and liquid, the other more denſe and viſcous, and of a ſomewhat whiter colour; but in old and ſtale eggs, after ſome days incubation, inclining to a yellow. As this ſecond albumen covers the yolk on all ſides, ſo it is itſelf ſurrounded by the other external liquid.

As the eggs of hens conſiſt of two liquors ſeparated from one another, and diſtinguiſhed by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; ſo it is very probable they are of different natures, and conſequently appointed for different purpoſes. Ariſtotle ſays, "That the vitellus is condenſed by cold, the albumen rather liquefied. On the contrary, the albumen is condenſed by fire; the vitellus retains its ſoftneſs, if it be not burnt; and concretes more in boiling than in roaſting." When the vitellus grows warm with incubation, it becomes more humid, and like melted wax or fat, whence it takes up more ſpace: for as the fœtus increaſes, the albumen inſenſibly waſtes away and condenſes; the vitellus, on the contrary, ſeems to have loſt little or nothing of its bulk; when the fœtus is perfected, and only appears more liquid and humid, when the abdomen of the fœtus begins to be formed.

The chick in the egg is firſt nouriſhed by the albumen; and, when this is conſumed, by the vitellus, as with milk. The albumen waſtes in keeping, and that through the ſhell, eſpecially if it be expoſed to a gentle heat: and it is ſpecifically lighter than the vitellus.

By incubation the albumen becomes thinner and more turbid, eſpecially on its upper part, near the obtuſe end, where it is alſo firſt conſumed; and it is afterwards diminiſhed towards the ſharp end of the egg, till at laſt nothing of it is left, except a white cretaceous ſubſtance at the lower part of the ſhell. In the Edinburgh Medical Eſſays, we are told that the albumen of a fœcundated egg is as ſweet and free from corruption, during all the time of incubation, as it is in a new-laid egg.

As the white of an egg has all the requiſites to the formation of an animal body, that is, to nutrition, when properly applied by the vital actions to the parts which require it, and this without any previous digeſtion by the ſtomach, it muſt neceſſarily be one of the moſt proper aliments in the world, in morbid caſes, where the d geſtive organs are relaxed and weak, where the fibres of the whole body want a due tenſion and elaſticity, and where conſequently reſtoratives are indicated. But in order to anſwer any good purpoſe in this view, it muſt be given freſh, raw, and without the application of the leaſt heat: for heat, as Boerhaave found by his experiments, renders it unfit for nutrition. It is to be given in a little milk and water, or broth, or may be taken alone, well ſeparated from the yolk.

The white of an egg has a refrigerating, aſtringent, and agglutinating quality.

The yolk is endued with an anodyne, maturating, digeſting, and relaxing virtue. Hence it is very often an ingredient in clyſters, and mixed with a little ſalt, is commonly applied, in a walnut ſhell, to the navels of infants, in order to looſen the belly.

EGG, in architecture, is an ornament in that form, cut in the echinus or quarter round of the Ionic and Compoſite capitals. The profile or contour of an echinus is enriched with eggs and anchors placed alternately.

EGLANTINE, in botany, a name frequently given to the ſweet-briar, a ſpecies of roſe. See the article ROSE.

EGYPT, an extenſive country of Africa, lying between the thirtieth and thirty-ſixth deg. of eaſt long. and between the twenty-firſt and thirty-firſt of north latitude. It is bounded by the Mediterranean on the north; by the Red-ſea and Iſthmus of Suez, which divide it from Arabia, on the eaſt; by Abyſſinia or Ethiopia, on the ſouth; and by the deſarts of Barca and Nubia, on the weſt; being ſix hundred miles in length from north to ſouth; and from one hundred to two hundred in breadth from eaſt to weſt.

Egypt is ſubject to the grand ſignior, and governed by a baſhaw, or viceroy. It owes its fertility to the annual over-flowing of the Nile, which it begins to do in the months of May and June, and is uſually at its height in September, from which time the waters decreaſe till May or June again. By this ſupply of water, Egypt is rendered ſo fruitful, as to ſerve Conſtantinople and other places with corn, as it did Rome and Italy of old. They only harrow their grain into the mud, on the retiring of the water; and in March following, uſually have a plentiful harveſt: and the lands, not ſown, yield good crops of graſs for the uſe of the cattle. According to Mr. Sandys, no country in the world is better furniſhed with grain, fleſh, fiſh, ſugar, fruits, melons, roots, and other garden ſtuff, than the Lower Egypt.

EJACULATOR, a muſcle of the penis, otherwiſe called the elevator.

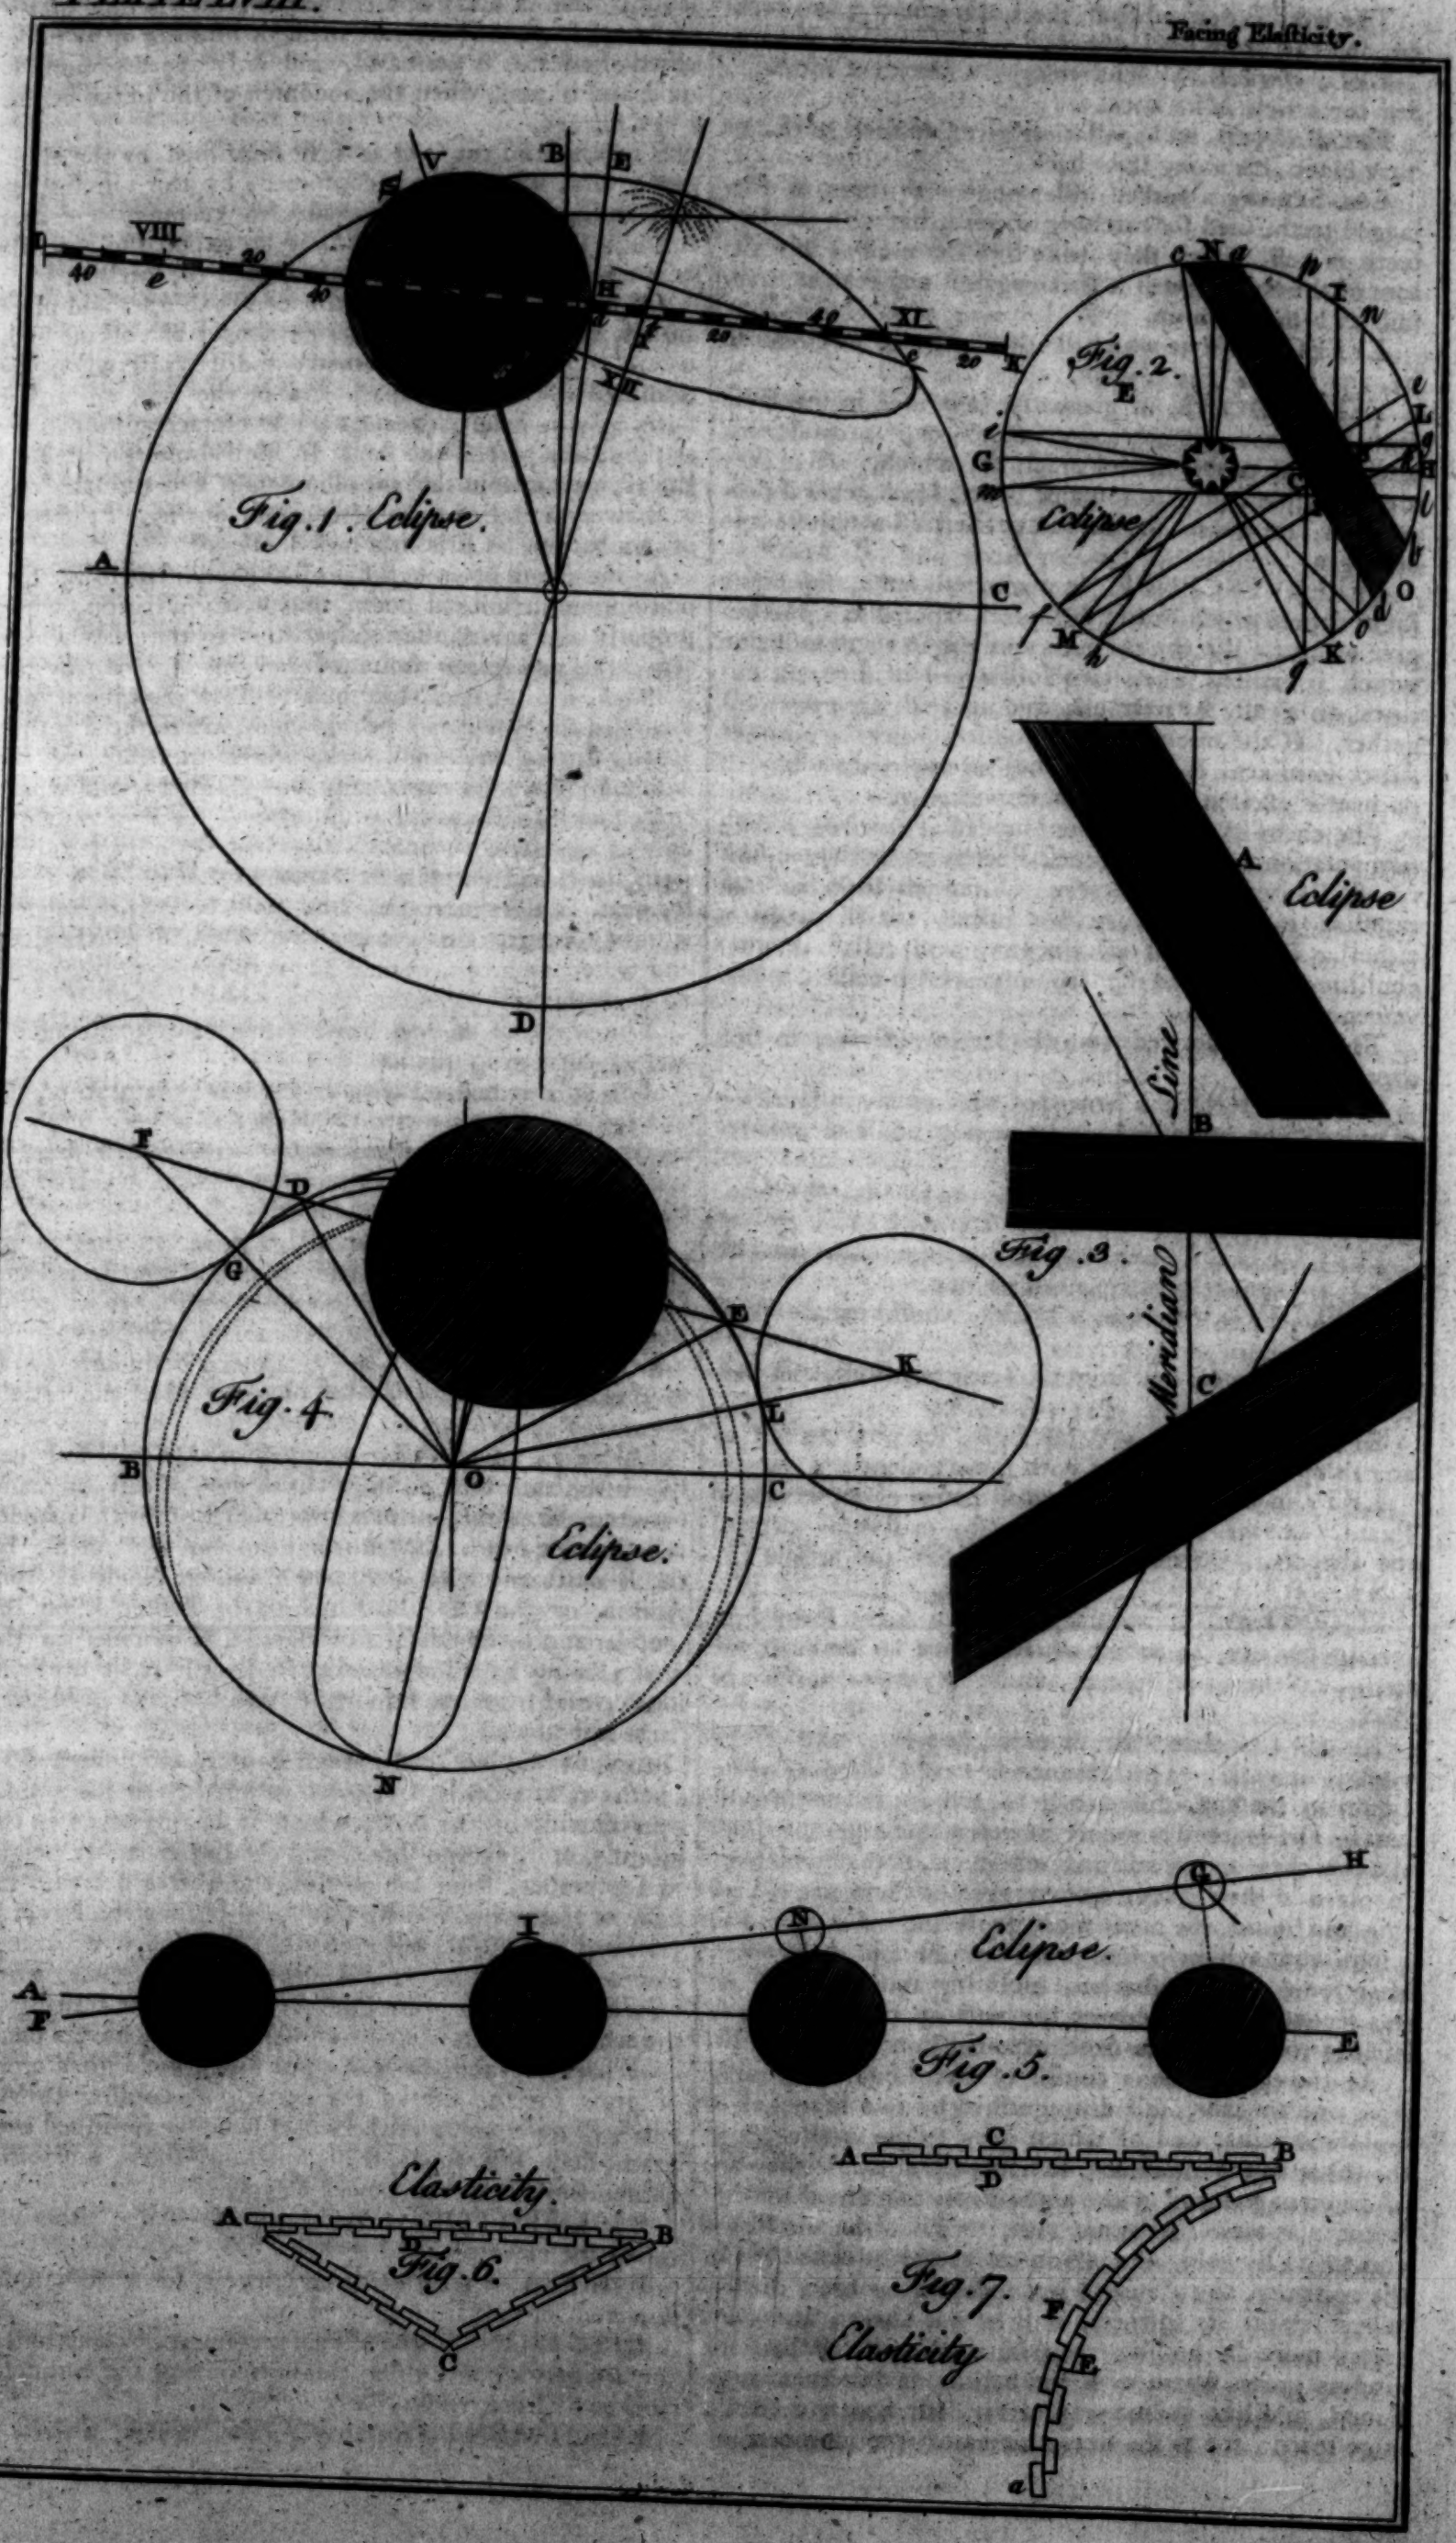
EJECTA, a term uſed, by lawyers, for a woman deflowered, or caſt from the virtuous.

EJECTION, in the animal œconomy, evacuation, or the diſcharging any thing through ſome of the emunctories, as by ſtool, vomit, &c.

EJECTMENT, *Ejectione Firmæ*, in law, a writ, or action,

PLATE LVIII.

Facing Elasticity.



5 1A 59

action, which lies for the leſſee for years, on his being ejected, or put out of his land before the expiration of his term, either by the leſſor, or a ſtranger. It may alſo be brought by the leſſor againſt the leſſee, for rent in arrears; or holding over his term, &c.

EIGHT, or PIECE OF EIGHT. See the article EXCHANGE.

ELABORATORY, the place where chemical proceſſes are performed. See CHEMICAL *Laboratory*.

ELÆAGNUS, dutch myrtle, in botany, a genus of trees, the characters of which are, that it has no flower petals; the fruit is an oval, obtuſe, and ſmooth drupe, including an oblong kernel or nut.

ELÆOSACCHARUM, in pharmacy, a preparation of ſome eſſential oil with ſugar, thus performed: grind an ounce of dry loaf-ſugar to an impalpable powder, in a glaſs mortar, and with a glaſs peſtle, and by degrees add thereto a dram of any eſſential oil, or only half a dram, if the oil be very tenacious; and continue rubbing them together, till all the oil be thoroughly mixed, and drank in by the ſugar. If a little freſh white of an egg be added in the grinding, the oil becomes thereby more eaſily miſcible; but the mixture will not keep ſo long, without turning rancid.

If theſe elæoſaccharums be well prepared, dried, and put into clean glaſſes, exactly cloſed with glaſs ſtoppers, they may be preſerved a long time perfect. By this method, therefore, you may prepare an excellent medicine, rich in virtue: for if the elæoſaccharum of mint be diſſolved in diſtilled mint-water, then ſtrengthened with the addition of ſpirit of mint, and the mixture ſweetened with the ſyrup of the ſame plant, the whole virtues of mint may be thus obtained.

ELAPHOCAMELUS, in zoology, the ſame with the glama, or Peruvian camel. See GLAMA.

ELASTIC, in natural philoſophy, an appellation given to all bodies endowed with the property of elaſticity.

ELASTICITY, that power or property in natural bodies, by which they reſtore themſelves ſpontaneouſly to the figure and dimenſions which they had loſt by the action of ſome other body applied to them.

Thus a ſpring or bow, when bent, reſtore themſelves, by their elaſticity, to the form they obtained before any external force was applied to them. And thus the arteries of an animal body, after being diſtended by the impulſe of the blood, contract and reſtore themſelves, by their elaſticity, to the ſame form and dimenſions they had before they were thus diſtended. Some have endeavoured to ſolve elaſticity by attraction only; as for example, if the ſtring AB (plate LVIII. *fig.* 6.) be conſidered as made up of particles lying over one another in the manner repreſented at ADB; it is plain that, if the point D be forcibly brought to C, the parts will be pulled from each other; and when the force that ſtretched the ſpring ceaſes to act, the attraction of coheſion, which was hindered before, will take place, and bring back the ſtring to its former length and ſituation, after ſeveral vibrations. Now, tho' this ſeems to agree pretty well with the phœnomena of a ſtring in motion, it will by no means ſolve the elaſticity of a ſpring faſtened to one end, and bent either way at the other, like a knife or ſword-blade. For if ſuch a ſpring be bent from A to *a*, (*fig.* 7.) the particles on the ſide C, which now become convex, will be farther aſunder at F, while the particles at D, carried to the concave part E, will come cloſer together: ſo that the attraction, inſtead of making the ſpring reſtore itſelf, will keep it in the ſituation in which it is, as it happens in bodies that have no elaſticity, where, perhaps, only attraction obtains. Thus a plate of lead, a plate of copper, and a plate of ſoft iron ſtand bent.

But the moſt probable way of ſolving the elaſticity of ſprings, is to conſider both a repulſive, and an attractive property in the particles, after the manner of the black ſand, which is attracted by the load-ſtone, and has been ſhewn by the learned and ingenious profeſſor Petrus Van Muſchenbroeck to be nothing elſe but a great number of little load-ſtones.

The great law of perfectly elaſtic bodies is, that their relative velocity will remain the ſame before and after colliſion; that is, perfectly elaſtic bodies will recede from one another after the ſtroke, with the ſame velocity that they came together. Many curious phænomena may be explained from this property in bodies.

If the ivory ball A, (plate LIX. *fig.* 1.) weighing two ounces, ſtrike with the velocity 16 againſt B at reſt, weighing alſo two ounces; the body B will move forward after this ſtroke with the velocity 16, A remaining at reſt in its place: the reaſon of this is, that the body A loſes one half of its motion by ſtriking the equal body B, and the other half by the elaſticity of B, recovering its former figure. From this experiment, ſeveral pretty odd phœnomena ariſe: thus, if a row of ſhovel-board pieces, that is, metalline cylinders of about half an inch in height, and two inches diameter, be laid upon a ſmooth table, and you take a ſingle piece, and drive it againſt the row, the laſt piece off the row will fly off; for if A (plate LIX. *fig.* 2.) ſtrike the row of pieces B, C, D, E, F, G, H, I, in the direction A *a*, then will the laſt piece I fly off to *i*, with the ſame velocity that A ſtruck B: and whatever be the velocity of A, no other piece but the laſt piece I will fly off. But if you take two pieces, as A and B, (*fig.* 3.) and ſtrike them together againſt the row C, D, E, F, G, H, I, the two laſt pieces H and I, will fly off from the other end of the row with the ſame velocity that A and B made the ſtroke.

If three or more pieces are made uſe of to make the ſtroke, the very ſame number will fly off from the other end of the row; and it is to be obſerved, that the ſame will happen with equal elaſtic balls, ſuſpended in a row by ſtrings of the ſame length.

Again, if the elaſtic body A, (*fig.* 4.) weighing four ounces, ſtrike the quieſcent body B, weighing only two ounces, with a velocity equal to 12; then will the velocity of A, after the ſtroke, be 4, and that of B 16. Juſt the reverſe of this happens, when a leſſer body ſtrikes againſt a greater; in which caſe, the ſtriking or leſſer body will be reflected with one fourth of its firſt motion, and the greater be carried forward with a motion which is as 16.

The magnitude and motions of ſpherical bodies perfectly elaſtic, and moving in the ſame right line, and meeting each other, being given, their motion after reflection may be determined thus: Let the bodies be called A and B, and the reſpective velocities *a* and *b*; then, if the bodies tend the ſame way, and A, moving ſwifter than B, follows it, the velocity of the body A, after the reflection, will be $\frac{aA-aB+2bB}{A+B}$, and that of the body $B=\frac{2aA-bA+bB}{A+B}$; but if the bodies meet, then, changing the ſine of *b*, the velocity of A will be $\frac{aA-aB-2bB}{A+B}$, and that of $B=\frac{2aA+bA-bB}{A+B}$: and if either of theſe happen to come out negatives, the motion after the ſtroke tends the contrary way to that of A before it; which is alſo to be underſtood of the motion of the body A in the firſt caſe.

ELATERIUM, in pharmacy, imports in general any purging medicine; but is particularly applied to thoſe which operate with violence; hence the word was tranſferred to the wild cucumber and the preparations thereof. See the article *Wild* CUCUMBER.

ELATINE FLUELLIN, in botany, a genus of plants, the corolla of which conſiſts of four ovated, obtuſe, ſeſſile, patent petals: the fruit is an orbiculated great capſule, compreſſed globeways, containing four cells, and conſiſting of four valves; the ſeeds are numerous, lunulated, erect, and ſurrounding the receptacle in the manner of a wheel. This plant is an aperient, reſolvent, and vulnerary.

ELBOW, in anatomy, the juncture of the cubitus and radius; or the outer angle made by the flexure, or bend of the arm. See CUBITUS and RADIUS.

ELBOW, in architecture, a term uſed for an obtuſe angle of a wall, building, road, &c. which divides it from its right line.

ELCESAITES, in church hiſtory, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elceſai.

The Elceſaites kept a mean between the Jews, Chriſtians,

tians, and Pagans; they worſhipped but one God, obſerved the Jewiſh ſabbath, circumciſion, and the other ceremonies of the law. They rejected the Pentateuch, and the prophets; nor had they more reſpect for the writings of the apoſtles, particularly thoſe of St. Paul. They deteſted chaſtity and continence, and obliged their diſciples to marry. They acknowledged a Meſſiah, whom they called their great king; but we do not know whether they meant Jeſus Chriſt, or ſome pretended Meſſiah. They gave him a human form, but inviſible; the dimenſions of which were thirty-eight leagues in height, and ſo in proportion. They pretended that the Holy Ghoſt was a woman, and of the ſame ſize with the Meſſiah. They were much addicted to judicial aſtrology, magic, and enchantments: they held that it was lawful to renounce the faith with the lips, provided a man kept it in his heart.

ELDER, or SENIORS, in Jewiſh hiſtory, were perſons the moſt conſiderable for age, experience, and wiſdom.

ELDER is alſo a denomination ſtill preſerved in the Presbyterian diſcipline. See the article PRESBYTERIAN.

ELDER, in botany. See SAMBUCUS.

ELEATICS, a ſect of philoſophers of Elea, founded by Xenophanes, a Colophonian. He held all things to be incomprehenſible, but withal, maintained many dogmatical aſſertions. He held that God is one, incorporeal, eternal, all ſight, and all hearing, no way reſembling man: that this God is all things; that whatever is, is eternal; that there are infinite worlds, and thoſe immutable and eternal; that there are four elements; that the ſtars are certain clouds, ſet on fire when they riſe, and extinguiſhed when they ſet; that all comets, falling ſtars, and the like, are clouds, kindled by motion; that the ſun is a fiery cloud, extinguiſhed in its eclipſes; that the moon is a cloſe, compact, and habitable cloud; that there are many ſuns and moons in the ſeveral climates of the earth; that the ſun promotes generation, but the moon contributes nothing to it; that the ſun goes forward in infinitum, but to us ſeems to move circularly by reaſon of the great diſtance; that the clouds are a vapour drawn up by the ſun; that the earth was firſt founded and rooted, as it were, in an infinite depth; that the ſoul is a ſpirit; and that all divination is falſe, &c.

ELECAMPANE, in botany, a large plant, with long, wrinkled, oval, acuminated leaves, ſerrated about the edges, pale green above, and hoary underneath, joined cloſe to the ſtalk, which divides towards the top into ſeveral branches, bearing large yellow flowers of the radiated diſcous kind, followed by oblong ſeeds, winged with down: the roots are ſhort and thick, ſomewhat unctuous to the touch, brown, or blackiſh on the outſide, and whitiſh within. It is perennial, grows wild in moiſt rich ſoils, and flowers in June.

The freſh roots of elecampane have a weak, not very grateful ſmell; which, on thoroughly drying, and keeping them for ſome time, is greatly improved, and approaches to that of Florence orris. Chewed, they diſcover at firſt a kind of rancid glutinous taſte, quickly ſucceeded by an aromatic bitterneſs, which by degrees becomes conſiderably pungent.

This root ſtands recommended as a diaphoretic, ſtomachic, for promoting expectoration in humoural aſthmas and coughs, and for attenuating viſcid juices in general, and diſpoſing them to excretion: taken freely, it is ſaid to gently looſen the belly, and increaſe the urinary diſcharge. The doſe of the dry root in ſubſtance is from a ſcruple to a dram or two.

ELECT, *Electus*, among eccleſiaſtical writers, thoſe whom God has choſen, or predeſtinated to be ſaved. See the article PREDESTINATION.

ELECTION, the choice that is made of a perſon, or thing, in preference of any other; as, in the election of an emperor, of a pope, of a biſhop, of members of parliament, &c.

ELECTION is alſo the ſtate of a perſon who is left to his own free will, to take or do one thing or another, which he pleaſes.

ELECTION, in theology, ſignifies the choice which God, of his good pleaſure, makes of angels and men for the objects of his grace and mercy.

ELECTOR, a perſon who has a right to elect or chooſe another to an office, honour, &c.

Elector is particularly, and by way of eminence, applied to thoſe princes of Germany, in whom lies the right of electing the emperor; being all ſovereign princes, and the principal members of the empire.

ELECTORAL CROWN, or CORONET. See the article CROWN.

ELECTORATE, a term uſed as well to ſignify the dignity of, as the territories belonging to, any of the electors of Germany.

ELECTRICITY, a power or property in ſome bodies, as amber, ſealing-wax, &c. whereby they attract light bodies.

The ancients have obſerved that amber, when it is rubbed, attracts bits of ſtraw, down, and other light bodies. They called amber *electrum*; ſo that the name of electricity has been given to that property of attracting light bodies, which at firſt was thought peculiar to amber; but it has ſince been found to be in a vaſt many other kinds of ſubſtances, ſuch as Spaniſh wax, gum copal, all the reſins, and tranſparent bodies. It is to be remarked, that bodies ſuſceptible of electricity are divided into two claſſes: the one are electrical of themſelves, or *per ſe*, that is, they contain that quality in themſelves, and they need only be rubbed, to excite it: ſuch are thoſe already mentioned; and a large catalogue of them may be ſeen in Muſchenbroek. The others do not contain that virtue in themſelves, or they have ſo little of it, as to be reckoned to have none at all; yet they acquire it by communication, or by emanation derived to them from a body that is electrical *per ſe*. This ſecond claſs of non-electrical bodies *per ſe*, are all thoſe in general that are not compriſed in the firſt claſs. Mr. Dufay has found, that the greateſt part of the bodies of this ſecond claſs may be raiſed to the condition of electrical bodies *per ſe*, by means of heating them briſkly, or by uſing ſome other preparations; but by reaſon of theſe difficulties they are left in the number of non-electrical bodies *per ſe*.

There is ſcarce any ſubject in natural philoſophy that has given occaſion to more experiments and diſcoveries than electricity has done; for, about thirty-ſix years paſt, the learned in Holland, Germany, Italy, France, and England, have ſtrove to diſtinguiſh themſelves upon this head. Mr. Gray, of the Royal Society at London, and M. Dufay, of the Academy of Sciences at Paris, have, in particular, carried this matter very far, by communicating the reſult of their labours to each other, and verifying them reſpectively, by a kind of concurrence of friendſhip and emulation, whoſe polite and uncommon unanimity has done as much honour to theſe learned men, as it has been of ſervice to promote this part of philoſophy.

M. Boze in Germany, and the Abbé Nollet in France, ſeem to have ſucceeded to theſe two great men; and they have already left them pretty far behind, by the ſingularity and number of their diſcoveries.

We ſhall confine ourſelves to the principal circumſtances of electricity, and pitch upon ſuch experiments as are moſt proper to confirm theſe circumſtances, and to diſcover their cauſes; and laſtly, endeavour to account for this phænomenon.

We are not only certain, that a great number of ſubſtances, which the antients did not ſuſpect to be electrical, as amber is, attract, like it, light bodies; but farther we have diſcovered, that all theſe ſubſtances, after they have attracted theſe bodies, do likewiſe repel them. So that hence alone we have in the phænomenon of electricity two contrary effects, attraction and repulſion.

Afterwards, by rubbing electrical ſubſtances in a dark room, it has been found, that they emitted ſome ſparks of light, and that thus the electrical body was a kind of phoſphorus. Upon bringing the finger within a line or two of the electrical body, the finger not only drew a ſpark out of this body, but farther, this ſpark made a little noiſe, and cauſed a pretty lively pricking in the finger.

At laſt, curioſity led philoſophers to examine, whether theſe effects of electricity might not be communicated to other bodies that were not naturally electrical, and they found that they were communicated to all bodies

in general, except flame, and that at very great diſtances; and that it was almoſt the ſame cauſe with electricity as with ſound and light.

Theſe are the chief effects, which, till the year 1745, were allowed to be in the phœnomenon of electricity; namely, attraction, repulſion, the emanation of ſparks, and the communication or propagation of all thoſe effects.

Of Attraction, the firſt Effect of ELECTRICITY.—The firſt and moſt ſimple phœnomenon of electricity is the attraction of light bodies by electrical or electrified bodies. This firſt property of electrical bodies is, to ſpeak the language of the ancients, the only phœnomenon to which the term electricity correſponds. This is electricity itſelf, ſince this word ſignified formerly the attraction produced by amber and other bodies of the ſame nature: however, modern philoſophy having diſcovered in theſe very ſubſtances the quality of repelling light bodies, as alſo that of producing light; and all theſe effects being naturally produced by the ſame cauſe; it is natural to call this general cauſe by the name of electricity, and to give theſe different effects the names of attraction, repulſion, &c. by joining thereto the epithet of electrical. The manner in which this phœnomenon of electricity is excited is as follows:

Get a tube of about three feet and a half in length, an inch and a half in diameter, and its ſides a line thick; let this tube be very ſmooth and dry; rub it with a piece of ſtuff, paper, or, which is better ſtill, with the hand, provided it be very dry. You will ſucceed ſtill better, if your hands be rubbed with a little chalk or white lead; afterwards bring this rubbed tube near light bodies, ſuch as gold-leaf, down, &c. laid upon a glaſs ſtand a foot high, and three or four inches broad at top, or hung upon linen or ſilk threads, ſituated perpendicularly in the open air. It is to be obſerved that theſe threads are called proof threads, becauſe they obey the leaſt electricity, and becauſe they are made uſe of to examine if any matter be electrical. If it is a thread of linen or ſilk moiſtened, the down will be always attracted; but if it be a dry ſilk thread, it will be attracted and repelled alternately. But to return; the aforeſaid bodies, as they approach the tube, will be thrown even upon it with rapidity. Chooſe for making theſe experiments a cold and dry ſeaſon; for hot weather and a moiſt air are not favourable for them.

Of Repulſion, the ſecond Effect of ELECTRICITY.—After having rubbed the tube more violently than before, if you bring gold-leaf, down, or a peacock's feather near it, it will not only attract theſe light bodies, but afterwards repel them a great way off; and if you do this in ſuch a manner that the gold-leaf, for example, be perpendicularly repelled above the tube, and that it meet with no other body, it will ſuſtain itſelf in the air, always at the ſame diſtance from the tube, and you may convey it in this ſituation quite round the room; but if it touch any other body, it will come back and adhere to the tube; then it will be repelled anew, as at the firſt. It often happens that the gold-leaf adheres to the tube, and is not repelled, eſpecially if it fall flat upon it; and then you aſſiſt the repulſion by blowing upon it a little.

During the time that the gold-leaf is ſuſpended in the circumference of the tube's atmoſphere, if you preſent to it another non-electrified light body, it attracts it in the ſame manner as the tube itſelf would do; but if it be a heavy fixed body, it ſhall be attracted by that; and if two gold-leaves, having been repelled at the ſame time by the tube, come to meet, they will reciprocally repel each other in the ſame manner as the tube repels them.

M. Boze, profeſſor of philoſophy at Wittemburg, obſerving ſome inconveniencies in the uſe of the tube, introduced a globe of glaſs or of roſin.

The globe muſt be made of the ſame ſort of glaſs as the tube, not leſs than a foot diameter; but not too large, about two lines thick, and as equal in thickneſs as poſſible; for a thick glaſs performs the beſt.

It is not neceſſary that this ball or globe ſhould be exactly ſpherical; and the Abbé Nollet aſſures us, that after fifteen years practice, he found a chemiſt's receiver makes the beſt inſtrument, after its neck is cut down to about three or four inches, and this he capped on one pole with a pulley like that uſed by pack-thread ſpinners or cutlers, and armed at the other pole with a piece of hard wood, having at the ends two needles or broaches of iron or ſteel, that it may turn round very briſkly in a horizontal poſition. Of which apparatus you have an exact repreſentation in plate LIX. *fig.* 5. where A is the pulley; B the neck of the ball, to which the pulley is faſtened with a paſte made of pitch, bees-wax, and fine ſifted aſhes; C is the ſtopper that ſcrews into the hole made in the center of the pulley: the axis on which the ball turns is fixed to the center of this ſtopper; and beſides, there ſhould be two or three ſlant holes in this ſtopper for the better communication of the air. D is the calot or cup of about four inches diameter, made of hard wood, with a hollow or concave ſide juſt to receive and exactly fit the pole of the globe oppoſite to the pulley. This cup muſt be carefully faſtened to the glaſs with the ſame cement, but ſo carefully, that when the cement cools, the glaſs may not move; for if it do, it will certainly break.

The next thing is to provide a wheel-band, of the thickneſs of a pinion gooſe-quill, which ſhall run in the pulley; and a wheel of about four feet in diameter, by which the ball ſhall be made to turn regularly and briſkly on its axis.

You are to take care that this wheel be framed upon a ſtrong and ſecure foot; and let it have two handles, that two perſons may turn it together; which, ſays the Abbé, is the beſt method of operation.

The axis muſt be fixed about three feet and a half above the plank or foot on which the wheel, and the perſons who turn it, ſtand. The cord ſhould be made of gut, and to run very freely in the pulley; and the ball, as much as poſſible, clear of every thing; for if the ſphere of attraction be interrupted on any part, it deſtroys the efficacy of the whole.

A B (*fig.* 6.) is the foot-frame of a machine which the Abbé had made uſe of above ten years, made of ſound oak, of about three inches ſquare, in which are mortiſed the uprights of the frame C, D, E, *c*, *d*, *e*, at the diſtance of nine inches from each other, but of unequal heights. F, G, project about five inches from the bottom of the ends of the uprights, for the more ſolid retention of the machine. H, I, *b*, *i*, are the croſs parts of the frame, four feet eight inches long, which hold the longer uprights C, D, *c*, *d*; and theſe complete a frame of four feet two inches long, and nine inches broad within. E, *e*, are the two ſhorter uprights, and both of a height; over which runs a bar marked M, N, and are ſtrengthened with the pieces K, L, mortiſed in the uprights D, *d*. Upon the wood, M, N, which projects beyond the uprights, and is ſupported at that end by a bracket O, is placed the table repreſented in *fig.* 7. Y, Z, are the poſts on which the wheel hangs; and H, I, *b*, *i*, contain two ſockets for the reception of the axis of the wheel, which axis is ſecured by two braſs claſps *k l*, (*fig.* 8.) one of which is let quite into the wood, and the other is faſtened to the outſide by long iron ſcrews, which run through both the ſocket and the bar H, I, and are faſtened on the other ſide with a nut. The outer claſp ſhould have a hole in the middle to receive a little oil. The end of the axis, to which the handles are fixed, ſhould be an exact ſquare of nine or ten lines each ſide with the corners very ſharp, and the crank of each handle ought to be ten inches long.

The globe (*fig.* 9.) is placed on the table (*fig.* 7.) whoſe frame by means of two rules, P, *p*, Q, *q*, enters the grooves R, *r*, (*fig.* 9.) and is ſecured by the ſcrews S, X, which paſs through the openings T, V. And if you would paſs two balls on this table at a time, the other muſt be mounted in the ſame manner as that deſcribed in *fig.* 10. and ſo placed, as that the ſcrew S may go through the opening *t*.—Having thus deſcribed the apparatus, we ſhall relate ſome of the capital experiments which have been made therewith, and are as follow:

1. A long, pointed, piece of iron being laid on a frame of ſilken ſtrings, with one end about a quarter of an inch from the globe, will at the other end, which terminates in a conical point, emit a purple flame of electrical fire, diverging each way from the point, like the rays of the ſun from the focus of a burning-glaſs in a darkened room. This pencil of electric rays is viſible, even in the day-light,

but is extremely ſo in the room made dark; and if the finger be held within a quarter of an inch, it cauſes the fire to iſſue out in a greater quantity, and to appear much more luminous than before. See plate LIX. *fig.* 11.

2. The finger, being placed as above directed, within a quarter of an inch of the ſaid flame, will be ſenſible of a gentle blaſt of wind from the end of the iron; that is, the electrical fire will iſſue out of the point in ſuch a manner, as to blow againſt the finger very ſenſibly; and if the finger be held ſtill nearer, the large pencil of rays will be condenſed in ſuch a manner as to run out of the point upon the finger in a ſtream, or body, of denſe yellow fire, and ſtrike the finger like a gentle jet d'eau; and indeed the phœnomenon may be truly called a jet de feu. This electric flame is ſenſible alſo to the ſmell, and much reſembles, in that reſpect, the fire of phoſphorus.

3. While the flame continues to appear from the point of the iron, the finger being placed any where upon the iron, the flame at the end diſappears immediately; if the finger be taken off, it again inſtantly appears; and ſo, by putting the finger off and on ſucceſſively, the electric flame will appear and diſappear alternately. The reaſon whereof is, that when the finger is applied, the electric virtue all runs off upon the finger, as a non-electric body, and therefore cannot go to the pointed end to produce the flame, as it does when the finger is taken off.

4. If a muſket barrel, &c. be ſuſpended, and the finger applied near it, as within $\frac{1}{5}$ of an inch, the fire will forcibly iſſue out, and ſtrike it, and in ſtriking it will give a very ſenſible ſnap; and ſeveral fingers being ſucceſſively applied to the barrel, will cauſe ſeveral ſuch eruptions and ſnappings of the fire, which will be all very ſenſible to the feeling, to the eye, and to the ear; and produce a moſt extraordinary and entertaining phœnomenon.

5. If a chain, or hempen cord, be ſuſpended by ſilken ſtrings, all round the room, of any length you pleaſe, and one end thereof be hung by a loop acroſs the barrel, the electrical fire will inſtantly be tranſmitted through the whole length of the chain, and appear upon every part at the approach of the finger, and be heard to ſnap, and ſtrike with as great if not greater force, than from the gun-barrel itſelf. In this particular the electric fire ſeems to reſemble that of lightning.

6. If a ſponge, thorough dry, be hung on to the electrified barrel, it gives no appearance of fire, which ſhews it be an electric ſubſtance: but if, when the ſponge has been immerſed in water, it be ſuſpended to the barrel as before, and the finger or hand be applied near it, the fire iſſues out with conſiderable force and ſnapping, and the drops which, before the ſponge was electrified, fell very ſlowly, will now fall very faſt; if the room be darkened, theſe drops will appear to be drops of fire, and illuminate the baſon into which they fall.

7. If a capillary ſyphon be hung on to the ſmall cup of water, at the end of the barrel, and the finger laid acroſs the barrel to prevent the electric virtue going to the water, then, before the water is electrized, you obſerve the ſyphon to drop only, and that very gently; but when the finger is taken off, and the water becomes electrized, the ſyphon runs a ſtream; and if the room be dark, it iſſues from the ſyphon in the appearance of fire. See plate LIX. *fig.* 12.

8. If a phial of water be provided, and well corked, and a wire bended on the top be pierced through the cork, and thruſt down near the bottom of the phial, leaving the upper part ſtanding about two or three inches above the bottle; then laying this wire on the globe in motion, the wire receives the electricity from the globe, and the water will be impregnated therewith, the more as the wire is kept longer on the globe; then the perſon thus holding the phial in one hand is to approach a finger of his other hand near the middle part of the globe, and he will receive the electric eruption of fire with a very conſiderable ſnap and force, greater by much than what proceeds from the barrel alone; the reaſon is, becauſe all the electricity, running through the wire into the water, is there condenſed, as it were, and confined by the electric ſubſtance of glaſs, and ſo acts in a greater quantity, and therefore with a greater force, than when it iſſues from the barrel unconfined.

9. A perſon ſtanding on a large cake of roſin, at leaſt three inches thick, holding a chain faſtened to the gun-barrel, will be electrized; that is, he will be all over poſſeſſed with the electric virtue, and at the ſame time feel nothing of it, unleſs ſome perſon ſtanding by put his finger near to any part, and then the virtue will be emitted in form of fire from any part, and ſnap, and become very ſenſible to both the parties, but in a very innocent manner. See plate LIX. *fig.* 12.

10. The phial being electrified, as above, the whole company join hands, or communicate with each other by wires; then the operator, or perſon who ſtands firſt, at one extremity of the line, hangs the electrical phial on the barrel, when the perſon at the other extremity draws off the ſpark from the barrel; and at that inſtant all the company receive the ſhock, which they feel to their elbows, and in both their arms.

11. A perſon, ſtanding on roſin, holding the chain from the barrel, points his finger to the warm ſpirits of wine, and by communicating the electric fire thereto, kindles the riſing flame, and ſo ſets the whole on fire. In this manner any ſort of matter, which when warmed will ſend forth an inflammable vapour, may be ſoon and very eaſily ſet on fire.

12. If a load-ſtone, armed with iron, be hung on to the gun-barrel by an iron wire, the electric virtue will ruſh out from every part, but more forcibly from the iron than from the ſtone itſelf; from the ſtone it ſeems to be emitted in a more lax manner, and diffuſed in a ſort of ſtream or fiery vapour; whereas from the iron it iſſues in a more impetuous, denſe, and penetrating ſtream. By this experiment we ſee that the two moſt conſiderable powers of nature, electricity and magnetiſm, do no ways interfere, or impede each other's action.

13. If the globe be exhauſted of all its air, and then whirled about, the electricity will be obſerved to act wholly within the globe, where it will appear, in a darkened room, in form of a cloud, or flame of reddiſh or purple coloured light, filling the whole capacity of the globe. This voluble flame will be diminiſhed and diſappear by degrees, as the air is gradually admitted into the globe: the reaſon why the action of the electric virtue does not ſhew itſelf outwardly, is the ſtrong repulſive power of the electric effluvium, and cauſing it to tend inwards, where it meets with no reſiſtance in a vacuous ſphere.

The above are the principal experiments uſually performed; to which we ſhall add the following, as it is not generally known, and at the ſame time exhibits a very curious and uncommon phœnomenon. Let two perſons ſupport a ſword between them on the top of their fingers; that is, let both perſons claſp all their fingers except the index, or fore-finger, and on the top of theſe place the guard of the blade, or that plate that ſeparates the blade from the hilt; ſo that the point of the ſword may hang down in a perpendicular direction towards the floor: then let one of the above perſons rub, with his other hand, the cryſtal of his watch, or a ſmall glaſs globe, bottle, &c. up and down his breaſt; and in a very ſhort time the ſword will begin to move in a circular direction on the two fingers that ſupport it; and continue that motion as long as the perſon continues to rub the glaſs globe, cryſtal, &c.

From the above experiments it appears that the force of the electric matter is very great; but nothing when compared with what may be called the celeſtial electricity; for it has been found, that the effects of lightning and thoſe of electricity are ſimilar. Lightning has been known to ſtrike people blind, the electrical ſhock has had the ſame effect on animals. Animals have been killed by both. The mariner's compaſs has ſometimes loſt its virtue by lightning; and by Mr. Franklin's experiments it appears, that polarity may be given and reverſed by electricity. The late Mr. Stephen Gray obſerved ſeveral years ago, that the electrical fire ſeemed to be of the ſame nature with that of thunder and lightning: others have ſince been of the ſame opinion. And indeed it appears, from various experiments, that the flame of electricity has been juſtly called by Mr. Franklin, a mimic lightning, ſince it blinds and kills animals, and melts metals, &c. like natural lightning.

This analogy is now farther confirmed by the diſcovery

made in France, in conſequence of Mr. Franklin's hypotheſis, of being able, by a proper apparatus, to collect the electricity from the atmoſphere during a thunder-ſtorm. For a pointed bar of iron, forty feet high, having been placed upon an electrical body, and a ſtormy cloud having paſſed over the place where the bar ſtood, thoſe that were appointed to obſerve it drew near, and attracted from it ſparks of fire, perceiving the ſame kind of commotions as in the common electrical experiments. The like effect followed, when a bar of iron ninety-nine feet high was placed upon a cake of roſin, two feet ſquare, and two inches thick: for a ſtormy cloud having paſſed over the bar, where it remained half an hour, ſparks were drawn from the bar. Theſe were the firſt experiments made in France, and they have been ſufficiently varied and verified ſince; ſo that it ſeems now certain, 1. That a bar of iron, pointed or not, is electriſed during a ſtorm. 2. That a vertical or horizontal ſituation is equally fitting for theſe experiments. 3. That even wood is electriſed. 4. That by theſe means a man may be ſufficiently electriſed to ſet fire to ſpirit of wine with his finger, and repeat almoſt all the uſual experiments of artificial electricity; for ſuch may that which is excited by friction be denominated.

It is, however, to be remarked, that theſe phœnomena are attended with irregularities, and do not always ſucceed perfectly. Sometimes ſimple clouds, without thunder or lightning, produce more electricity than when there is loud thunder. Sometimes the electricity does not ſhew itſelf but where there is lightning: in other caſes, the electricity, which ſeemed diſſipated during the rain, began again as ſoon as the rain ceaſed, although the thunder was very diſtant.

Mr. Franklin has contrived a very ingenious and eaſy way of trying experiments of this kind by means of an electrical kite, made of a large thin ſilk handkerchief, extended and faſtened at the four corners to two ſlight ſtrips of cedar, of ſufficient length for this purpoſe. This kite, being accommodated with a tail, loop, and ſtring, will riſe in the air like thoſe of paper. To the top of the upright ſtick of the croſs is to be fixed a very ſharp-pointed wire, riſing a foot or more above the wood. To the end of the twine, next the hand, is to be tied a ſilk ribbon; and where the twine and ſilk join, a key may be faſtened. The kite is to be raiſed when a thunder-guſt appears to be coming on, and as ſoon as the thunder clouds come over the kite, the pointed wire will draw the electric fire from them, and the kite with all the twine will be electrified; and the looſe filaments of the twine will ſtand out every way, and be attracted by an approaching finger. When the rain has wet the kite and twine, ſo that it can conduct the electric fire freely, it will ſtream out plentifully from the key on the approach of a man's knuckle. At this key the phial may be charged; and from electric fire thus obtained ſpirits may be kindled, and all the other electrical experiments be performed, which are uſually done by the help of a rubbed glaſs globe or tube, and the ſameneſs of the electric matter with that of lightning may thereby be completely demonſtrated.

Laws, &c. of ELECTRICITY.—Mr. Ellicott, from carefully obſerving the various phœnomena of electricity, thinks that the following concluſions, or general laws, may be juſtly deduced from the phœnomena.

1. That theſe remarkable phœnomena are produced by means of effluvia; which, in exciting the electrical body, are put into motion, and ſeparated from it.

2. That the particles compoſing theſe effluvia ſtrongly repel each other.

3. That there is a mutual attraction between theſe particles and all bodies whatſoever.

Mr. Watſon has endeavoured to prove, that electricity is not furniſhed from the glaſſes employed in the experiments, nor from the circumambient air. He thinks that electricity is the effect of a very ſubtile and elaſtic fluid, occupying all bodies in contact with the terraqueous globe, and that every where in its natural ſtate it is of the ſame degree of denſity; and that glaſs, and other bodies which are called electrics *per ſe*, have the power of taking this fluid from one body, and conveying it to another, in a quantity ſufficient to be obvious to all our ſenſes; and that under certain circumſtances, it is poſſible to render the electricity in ſome bodies more rare than it naturally is; and, by communicating this to other bodies, to give them an additional quantity, and make their electricity more denſe; and that theſe bodies will thus continue until their natural quantity is reſtored to each; that is, by thoſe which have loſt part of theirs, acquiring what they have loſt, and by thoſe to which more has been communicated, parting with their additional quantity. Both the one and the other of theſe is, from the elaſticity of the electric matter, attempted to be done from the neareſt non-electric; and when the air is moiſt, this is ſoon accompliſhed by the circumambient vapours, which here may be conſidered as preventing, in a very great degree, our attempts to inſulate non-electric bodies.

Mr. Watſon's ſyſtem naturally leads him to aſk, by what denomination ſhall we call this extraordinary power? From its effects in theſe operations, ſhall we call it electricity? From its being a principle neither generated nor deſtroyed; from its being every-where and always preſent, and in readineſs to ſhew itſelf in its effects, though latent and unobſerved, till by ſome proceſs it is produced into action, and rendered viſible; from its penetrating the denſeſt and hardeſt bodies, and its uniting itſelf to them; and from its immenſe velocity; ſhall we, with Theophraſtus, Boerhaave, Niewentiit, s'Graveſande, and other philoſophers, call it elementary fire? Or ſhall we, from its containing the ſubſtance of light and fire, and from the extreme ſmallneſs of its parts, as paſſing through moſt bodies we are acquainted with, denominate it, with Homberg and the chemiſts, the chemical ſulphureous principle, which, according to the doctrines of theſe gentlemen, is univerſally diſſeminated? Whatever we call it, it ſeems certain, that this power has many ſurpriſing properties, and cannot but be of great moment in the ſyſtem of the univerſe.

ELECTROMETER, an inſtrument contrived to meaſure the force of electricity.

M. d'Arcy, in the Memoirs of the Royal Academy of Sciences at Paris, has given us the following curious electrometer.

Plate LIX. *fig.* 13. is a large veſſel A B, containing a glaſs bottle C D, called the philoſophical egg; at the extremity of the neck of this bottle is fitted on the rod V, perfectly cylindrical, one line in diameter and twelve inches long. The veſſel A B is covered again at the top with a plate of braſs H, which fits cloſe upon it; this plate has a large perforation at its center, and ſo has the veſſel, that the rod may paſs through at liberty. At the upper extremity of the rod is the ſmall circular plate of braſs L, fourteen lines one ſixth diameter. The veſſel A B being full of water, the egg is immerſed to a certain depth, which ought to be ſuch, that the inſtrument being at reſt, that is, not electrified, the lower extremity of the egg may be as near as poſſible to the bottom of the veſſel without touching it. That the egg and rod may always be in a vertical ſituation, the egg is ballaſted with mercury, by which means, the center of gravity being very low, the whole keeps itſelf perpendicular to the horizon, and proves by the leaſt poſſible motion of the egg, from its balance, that if it were not confined, it would go towards the ſides of the veſſel, and ſwim ſometimes on one ſide and ſometimes on the other; wherefore it was neceſſary to determine it to a center in the following manner: on the plate H are fixed fine ſilver wires in the form of a croſs, like thoſe in micrometers; this croſs is formed by double wires, having a ſmall ſquare ſpace in the center of the plate, which, being larger than the diameter of the rod, permits it to aſcend and deſcend between the wires without any ſenſible friction, and yet reſtrains it from erring from its center: and this ſingular phœnomenon ariſes, when the whole machine is ſtrongly electrified, namely, the rod keeps in the middle of the wires almoſt without touching them, becauſe, being electrified as well as they, it avoids them continually.

After this deſcription of the inſtrument, it is eaſy to conceive its uſe, eſpecially if we attend to this known principle in hydroſtatics, that a body immerſed in water ſwims on the ſurface or ſinks in it, in proportion as a volume of water, equal to that it poſſeſſes, is lighter or heavier than the body itſelf; from this principle it follows, that a volume of water equal to that of the egg,

and

and that part of the rod immerſed in the water when the whole is at reſt, was equal to the egg, the little plate, and all the rod: conſequently, if the whole be elevated one inch, the power which will ſuſtain it at this height, will ſuſtain a weight equal to a volume of water of the thickneſs of the rod, and an inch in height; becauſe the volume of water which the egg and rod then poſſeſs, is leſſened by this quantity. If, therefore, different powers ſuſpend it at 1, 2, 3, 4 inches, &c. in height, above the point of reſt, theſe powers will be, with regard to each other, as theſe numbers, double, triple, quadruple, &c. You will ſee in a moment that electricity produces the ſame effect upon the electrometer; that is, it performs the function of a power which would ſuſpend it at 1, 2, 3, 4 inches, &c. above its point of reſt; and, conſequently, that by means of this inſtrument we may eſtimate all its different degrees of force. Let us ſuppoſe, for example, the whole machine compoſed of the veſſel A B, the egg, &c. placed like that in *fig.* 14. on a recipient of glaſs or any other electric *per ſe*. Electrify the veſſel A B, the rod V and plate L will become electrified alſo. Now it is admitted that all electrical bodies repel each other: thus the little plate L and the rod V, being repelled by the great plate H, will neceſſarily riſe more or leſs in proportion to the ſtrength or weakneſs of the electricity. Electricity therefore will, as has been already obſerved, perform the function of a power that will ſuſpend the inſtrument to a certain elevation; but as theſe powers are proportional to the elevations of the inſtrument above its equilibrium, or point of reſt, theſe elevations alſo will be in proportion to the different degrees of the force of electricity: this is therefore a true electrometer. But this inſtrument is of much more extenſiveneſs than barely this; for it may be employed in a great number of electrical experiments to determine the laws of attraction, repulſion, tranſmiſſion, &c. in electrical bodies: diſcoveries equally important with that of menſurating electrical force.

Method of uſing the ELECTROMETER.—As electrical bodies have this inconvenience, that they cannot be approached without deſtroying their electricity, it is evident that, if we come ſo near the electrometer as to judge of its motions with exactneſs, we ſhould deſtroy its electricity. This reaſon determined M. d'Arcy, after a number of attempts, to make his obſervations in the following manner: he placed a capacious lantern with a large wax candle, in a part of the room which projected its light through a hole on the electrometers I, K (we have not drawn the lantern in the plate, for fear it might have cauſed ſome confuſion, and have therefore only exhibited the ray of light); behind theſe electrometers is a very ſolid frame Q, all the part X is wood, but it may conſiſt of any opaque matter. In this frame are cut two rectangular apertures or windows filled with glaſſes, on which are marked very exact diviſions with ſtrong Indian ink.

This frame is ſo diſpoſed that the projection of the electrometers may fall upon the glaſſes, and the extremity of the rod D, being made in the form of a cone, projects a very nice ſhadow. Now, as theſe glaſſes are tranſparent, the obſervator, placed behind in F, ſees, in the moſt diſtinct manner, all the different elevations of the electrometer, and can therefore judge of all its variations with the utmoſt exactneſs; for the plane of the ſquare being perpendicular to the horizon, and the electrometer riſing and falling in a parallel plane, the elevations and depreſſions of the ſhadows are always correſpondent to thoſe of the electrometers. The chains M ſerve to conduct the electricity from the bar of iron or any other electrified body to the electrometers: the ſquare Q, inſtead of two windows, may have but one, that being ſufficient for the electrometer: but M. d'Arcy thought it adviſeable to make his obſervations on the inſtrument with which he made his experiments, and the electrometer too, in order to be aſſured that the electricity is always equal, which cannot be done without comparing their ſhadows very accurately. The conſtruction of the electrometer ſhews, it has all the eſſentials of an inſtrument of this kind.

1. As the electrical force is very weak, the inſtrument muſt be very nice and ſenſible of the leaſt impreſſion: therefore the weight of eight grains laid on the little plate L makes it ſink above four inches.

2. As the electrical force is very ſubject to alterations, the inſtrument muſt be ſo contrived as to exhibit all its variations; and a thouſand experiments have ſhewn that the leaſt alteration in the force of electricity, immediately affects this electrometer. It is in ſhort univerſal, for the true electrometer is the cylindrical rod V, which determines the quantity of electrical power by the number of its parts raiſed above the point of reſt: now it is not difficult to procure a cylindrical rod of a line diameter. It is true the diameter of the little plate L, and its diſtance to H, the point of reſt, may cauſe ſome difference in the repulſion; but it is eaſy to obſerve all theſe proportions, ſo that any one may conſtruct an electrometer, which will be equally operated upon, by the ſame power of electricity: this property ſeems to be one of the moſt remarkable in his inſtrument, like that of M. Reaumur's thermometer, which all Europe has admired. As this electrometer may be uſed as an inſtrument, it may be neceſſary to give ſome account of the experiments that have been made. In order to diſcover whether electricity is in proportion to the bulk or ſurface of bodies, M. d'Arcy proceeded in the following manner: the inſtrument E ſerved for an electrometer, the other I was deſigned to make the experiment on; above this laſt was ſuſpended perpendicularly, at the diſtance of ten inches, a cap or portion of the ſphere P S; this cap was of hammered iron, very thin, and of a very regular figure; it received its electricity from the electrical bar by a braſs wire, and, being ſuſpended on ſilk, preſerved it. The chain in *fig.* 14. extends to both inſtruments, but in this experiment it only communicated with the electrometer, ſo that the inſtrument was not electrified. M. d'Arcy ſays one perſon made his obſervation on the ſquare of the height of the electrometer cauſed by the electricity, while another obſerved the elevation of the inſtrument; and ſeveral repeated experiments confirmed them in the opinion that the elevation of the inſtrument was in proportion to the force of the electricity; and this they found to anſwer exactly, after having repeated the experiment above fifty times. He afterwards poured mercury into this cap till it increaſed the weight ſixty times, and found no ſenſible alteration in the experiment: this ſeems to ſhew that the attraction of electrical bodies is in proportion to their ſurfaces; but this is a matter of doubt, for the fire and ſparks drawn from an electrical body may obſerve ſome other law. Certain it is, that a piece of any metal muſt be of a certain thickneſs to extract ſhining ſparks from it, otherwiſe you only procure ſuch a kind of fire as is extracted from electrified wood of any thickneſs; yet the ſparks extracted from the middle of a plate of iron are very ſtrong; and thoſe extracted from the cap, either with or without mercury, ſeemed to have no difference. In ſhort, by a multitude of experiments M. d'Arcy found that the gravity or levity of a body neither increaſe nor diminiſh its electricity.

We ſhall add another experiment made by M. d'Arcy, in order to know whether an electrical body always tranſmitted the ſame quantity of electricity, of whatever volume it was. Every thing being diſpoſed, as in *fig.* 14. except that the inſtrument with which he made his experiment, inſtead of communicating with the iron bar by a chain, had a communication with it by a very fine iron wire; he electrified the bar of iron, and made his obſervations on the electrometer and the inſtrument: he afterwards ſubſtituted a much thicker wire in the room of the fine one, and repeated the experiment, but did not find the leaſt difference in the reſult, though it was performed ſeveral times with wires of all the different ſizes that could be procured.

The objections to M. d'Arcy's electrometer are of three kinds, its certainty, univerſality, and the method of making uſe of it. It may be aſked in the firſt place, whether the egg immerſed in water be not more or leſs repelled by the bottom of the veſſel, which would affect the electrometer, without any alteration in the electricity? In anſwer to this, a body totally immerſed in a fluid, receives no motion from electricity; and this is a fact confirmed by experiments. 2. It may be aſked whether the bodies which tranſmit the electricity to the electrometer, may not act differently on the electrometer? The experiment already produced of wires of different magnitudes tranſmitting the ſame quantity of electricity, ſufficiently

proves electricity to have the property of fluids, which always endeavour to preſerve a plain ſurface, whatever are the canals of their communication. Beſides, it follows from this property, that the leaſt change of electricity, in a body compoſing the maſs of thoſe which are electrical, equally influences the whole maſs; which ſolves another objection that might be made againſt the veſſels of glaſs on which the electrometer is ſupported: it may be ſaid, that, being more or leſs dry, they might loſe their electricity, and the electrometer ſink, though there was no alteration in the electrical bodies themſelves: but the laſt property already mentioned, proves, that electricity, like a fluid, endeavours to preſerve an even ſurface, and is therefore acted upon equally; and this is ſupported by a number of experiments.

It may in the laſt place be objected, that the inſtrument, notwithſtanding all that has been ſaid about it, is too coarſe to be affected ſo nicely, and that we ſhall be apt to draw falſe conſequences from it; but the following experiment will ſhew this objection entirely groundleſs.

The iron bar which receives the electricity of the globe was placed at the diſtance of about twenty inches from it; a communication was made afterwards between this bar and the electrometer; and, the chamber being made very dark, M. d'Arcy began to electrify. The electricity which the bar received by this method was ſo weak, that he could ſcarce be ſenſible whether it was electrified or not, by trying to draw ſparks from it; and what were drawn, were ſo weak, they ſcarce deſerved the name; notwithſtanding which, the electrometer which had a communication with the iron bar roſe above a degree. This ſufficiently demonſtrates the nicety of the inſtrument, and how eaſily it is acted upon; this too might, if there was occaſion, be ſtill increaſed by leſſening the diameter of the rod.

But the ſtrongeſt objection againſt the univerſality of M. d'Arcy's inſtrument is the different denſity of water in different climates: but in anſwer to this he ſays, if a rod be made which will deſcend four inches with the weight of eight grains, the electrometer will be as correct as his. It may be objected, that in a hot country ſuch a rod might be more repelled, becauſe it would be bigger than the former; but, as the rod is only repelled in proportion to its circumference, the difference can ſcarce be perceivable.

ELECTRUM, amber, in natural hiſtory. See the article AMBER.

ELECTUARY, in pharmacy, a form in which both officinal and extemporaneous medicines are frequently made. It may be conſidered as a number of boluſes united together, but made a little ſofter by the addition of a due proportion of ſyrups, &c.

ELEGANCE, or ELEGANCY, an ornament of politeneſs and agreeableneſs, ſhewn in any diſcourſe, with ſuch a choice of rich and happy expreſſions, as to riſe politely above the common manners, ſo as to ſtrike people of a delicate taſte, and diffuſe a reliſh which affects every body.

It is obſerved that elegance, though irregular, is preferable to regularity without elegance; that is, by being too ſcrupulous of grammatical conſtruction, we loſe certain licenſes wherein the elegance of language conſiſts.

ELEGANCE, in painting, a certain manner which embelliſhes and heightens objects, either as to their form, colour, or both, without deſtroying or perverting the truth. It is not ſeen in the correctneſs of the deſign, as appears from Raphael, and the antique. It is moſt ſenſibly perceived in works otherwiſe careleſs and inaccurate, as in Corregio, where, notwithſtanding all the defects as to juſtneſs of deſign, there is an elegance even in the manner of the deſign itſelf, as well as in the turn of the attitudes, &c.

ELEGIT, in law, a writ of execution, which lies for a perſon who has recovered debt or damages; or upon a recognizance in any court, againſt a defendant that is not able to ſatisfy the ſame in his goods.

ELEGY, in poetry, primarily and generally implies a mournful poem.

The word is derived, according to Didymus, from ε, a particle of grief, and λεγω, to ſay, and according to others from ελεος, ſomething moving, and λεγω.

As elegy, at its firſt inſtitution, was intended for tears; it expreſſed no other ſentiments, it breathed no other accents, but thoſe of ſorrow. With the negligence natural to affliction, it ſought leſs to pleaſe than to move. By degrees, however, elegy degenerated from its original intention, and was employed upon all ſorts of ſubjects, gay or ſad, and eſpecially upon love.

Ovid's books of love, the poems of Tibullus and Propertius, are intitled elegies; and yet ſo far are they from being ſad, that they are ſometimes ſcarce ſerious: ſo that one and the ſame title was indiſcriminately given to poems on different ſubjects, but which agreed in their verſe and manner of writing. The chief ſubjects then to which elegy owes its riſe, are Death and Love: ſo that elegy ought to be eſteemed the moſt perfect, which has ſomewhat of both at once; namely, where the poet bewails the loſs of ſome youth, or damſel, falling a martyr to love. The next are thoſe elegies full of that melancholy complaint which lovers ſeldom want matter for: the thoughts of elegy ſhould be always natural, far from the affectation of wit; its ſentiments tender and delicate; its expreſſion ſimple and eaſy, always retaining that alternate inequality of meaſure which Ovid extols ſo much; and which gives the elegiac poetry of the ancients ſo much the advantage over the moderns. Elegy ſhould flow in one even current, ſmooth, humble, and unaffected; and yet ſhe is not abject in her humility, but becoming, elegant, and attractive.

Some early writers in this way, among the Greeks, were Callimachus, Philetas, Mimnermus, Callinus, and others, of whoſe writings only fragments have been ſaved. Quintilian gives the preference to Callimachus; but Horace ranks Mimnermus above him. Mimnermus is by ſome reckoned the inventor of elegiac verſe; he at leaſt gave it its perfection, and was perhaps the firſt who transferred it from funerals to love.

Among the Latins, Ovid, Tibullus, and Propertius, bear the firſt rank: there is ſcarce any thing of Catullus's elegiac, except the meaſure of ſome of his verſes; and thoſe ſo rough, that they cannot be read without great offence to the ear. Ovid is generally reckoned the firſt among the elegiac writers; yet Tibullus is leſs diffuſe and more correct. Ovid's perpetual repetition of *mei*, *tui*, and *ſui*, in the laſt foot of his pentameters, is unpardonable. Tibullus and Propertius rarely fall into this fault, but into another, eſpecially the latter, from which Ovid is free; and that is, concluding the pentameter with words of three or four ſyllables; whereas harmony requires a word of no more than two.

Among the ancients, hexameters and pentameters were ſo peculiar to elegy, that this kind of metre is uſually ſtyled elegiac. Inſtead of it, we, in our tongue, uſe the word heroic.

Among our modern poems, we have only ſome elegies on funeral occaſions; but we have many that may be called ſo in the larger ſenſe of the word, as uſed by the ancients; many very ingenious ones on love; and others of a melancholy and ſoft turn.

ELEMENT, in phyſiology, a term uſed by philoſophers to denote the original component parts of bodies, or thoſe into which they are ultimately reſolvable.

The elements of Ariſtotle were four, earth, water, air, and fire. See ARISTOTELIAN *Philoſophy*.

The Carteſians admit only three elements, the firſt a materia ſubtilis, or fine duſt; the ſecond, a coarſer, but round kind; and the third, a ſtill more irregular and hooked kind of particles. See the article CARTESIAN *Philoſophy*.

Concerning the true elements of nature, the incomparable Sir Iſaac Newton thus explains himſelf in his Optics: "It ſeems probable to me, that God in the beginning formed matter in ſolid, maſſy, hard, impenetrable, moveable particles, of ſuch ſigns and figures, and with ſuch other properties, and in ſuch proportion to ſpace, as moſt conduced to the end for which he formed them; and that theſe particles, being ſolid, are incomparably harder than any porous bodies compounded of them; even ſo very hard, as never to wear or break in pieces, no ordinary power being able to divide what God himſelf made one in the firſt creation. While the particles continue entire, they may compoſe bodies of one and the

ſame nature and texture in all ages: but, ſhould they wear away, or break in pieces, the nature of things depending on them would be changed. Water and earth compoſed of old worn particles, and fragments of particles, would not be of the ſame nature and texture, now, with water and earth compoſed of entire particles in the beginning: and therefore, that nature may be laſting, the changes of corporeal things are to be placed only in the various ſeparations and new aſſociations and motions of theſe permanent particles; compounded bodies being apt to break, not in the midſt of ſolid particles, but where thoſe particles are laid together, and only touch in a few points."

The chemical elements or principles to which all bodies may be ultimately reduced, are theſe five: 1. Water, or phlegm, which, in the chemical analyſis of them, riſes firſt in form of vapour. 2. Air, which eſcapes unſeen in great quantities from all bodies, ſo as to conſtitute half the ſubſtance of ſome of them. 3. Oil, which riſes after, and appears ſwimming on, the ſurface of the water. 4. Salt, which is either volatile, or riſes in the ſtill, as that of animal ſubſtances; or fixed, as that of vegetables, which is obtained by reducing them to aſhes, making a lixivium or ley of theſe, and afterwards evaporating the moiſture; by which means the ſalt ſhoots into cryſtals. 5. Earth, or what is called *caput mortuum*, being what remains of the aſhes after the ſalt is extracted. This is the laſt element of all bodies, which can be no farther altered by any art whatſoever. See WATER, AIR, &c.

ELEMENT, in a figurative ſenſe, is uſed for the principles and foundations of any art or ſcience, as Euclid's Elements, &c.

ELEMI, or ELEMY, is a reſin of Aſiatic origin: the plant which produces it is not as yet known with certainty. There is alſo an inferior kind, brought from America, which is the only one now to be met with in the ſhops: the parent of this ſort is called by Ray, *Arbor Brazilienſis gummi elemi ſimile fundens, &c.* a Brazilian tree, yielding a gum like elemi, with winged leaves, verticillate flowers, and a fruit about the ſize and ſhape of an olive.

The true elemi comes over in large oblong maſſes or round leaves, generally wrapt up in leaves of the Indian reed. It is of a yelloviſh or rather greeniſh white colour; ſemitranſparent; of a ſoft conſiſtence, betwixt that of wax and turpentine, or dry on the outſide and ſoftiſh within: by age, it grows hard and brittle throughout. It has a moderately ſtrong, not unpleaſant ſmell, reſembling that of a mixture of fennel, daucus, and ſmallage-ſeeds. It is commonly full of impurities, which are obvious enough to the eye.

This reſin has hitherto been employed only in external applications; in nervine, vulnerary, and digeſtive plaſters and balſams. In making theſe kinds of compoſitions, we muſt be careful to avoid too great a degree of heat in mixing the ingredients; leſt the eſſential oil, the moſt uſeful part of the elemi, be loſt.

ELENCHUS, in logic, a ſophiſm, or fallacious argument, which deceives the hearer under the appearance of truth. See the article SOPHISM.

ELEOSACCHARUM, or ELÆOSACCHARUM. See the article ELÆOSACCHARUM.

ELEPHANT, *Elephas*, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which, according to Linnæus, are theſe: it has no foreteeth; the upper canine, or dog-teeth, are conſiderable long; it has a very long flexible proboſcis or trunk, and two paps placed on the breaſt.

The teeth of this animal is what we call ivory. See IVORY.

The elephant, of which there is only one known ſpecies, is, when full grown, from ſeventeen to twenty feet high; and its body is withal ſo enormouſly bulky, that the belly reaches nearer the ground than could eaſily be conceived of a creature of its height. The trunk is, properly ſpeaking, nothing but the noſe continued to a great length; its ſubſtance is fleſhy, but firm, being compoſed of three ſeries or orders of fibres: this trunk the creature can contract or protrude forward with great violence, from the length of one foot to five or more.

Knights of the ELEPHANT, an order of knighthood in Denmark, conferred upon none but perſons of the firſt quality and merit. It is alſo called the order of St. Mary. Its inſtitution is ſaid to have been owing to a gentleman among the Daniſh croiſees having killed an elephant, in an expedition againſt the Saracens, in 1184, in memory of which king Canutus inſtituted this order, the badge of which is a towered elephant, with an image of the Holy Virgin encircled with rays, and hung on a watered ſky-coloured ribbon, like the George in England.

ELEPHANTIASIS, or ELEPHAS, in medicine, is a ſpecies of leproſy, ſo called, becauſe it affects the legs in ſuch a manner, as to make them appear like thoſe of an elephant. See LEPROSY.

The word is derived from the Greek, ελεφας, an elephant.

ELEPHANTOPUS, baſtard ſcabious, in botany, a genus of plants, the compound flower of which is tubuloſe, conſiſting of four or five hermaphrodite and ligulated corollulæ, with a narrow limb, divided into five nearly equal ſegments: the ſtamina are five very ſhort filaments: the ſeeds are ſolitary, and contained in the cup, being of a compreſſed figure, and crowned with briſtly hairs.

ELEVATION, *Elevatio*, the ſame with altitude or height. See ALTITUDE.

Angle of ELEVATION, in gunnery, that comprehended between the horizon and the line of direction of a cannon or mortar; or it is that which the chaſe of a piece, or the axis of its hollow cylinder, makes with the plane of the horizon.

ELEVATION, in architecture, the ſame with an orthographic, or upright draught of a building. See ORTHOGRAPHY.

ELEVATION *of the Hoſt*, in the church of Rome, that part of the maſs where the prieſt raiſes the hoſt above his head for the people to adore.

ELEVATOR, in anatomy, the name of ſeveral muſcles, ſo called from their ſerving to raiſe the parts of the body to which they belong: ſuch are the elevator alæ naſæ, the elevator of the auricle or external ear, the elevator of the epiglottis, of the eye-lids, humerus, lips, urethra, and thoſe of the anus, called alſo levatores. See MUSCLE.

The elevator of the eye-lids is alſo called ſuperbus, as being uſed when people put on a haughty or high look.

ELEVATOR, in ſurgery, an inſtrument to elevate or raiſe bones, as in fractures of the ſkull, &c.

ELEVE, a French term, ſometimes met with in the Engliſh language, ſignifying a diſciple or ſcholar.

ELEUSINIA, in Grecian antiquity, a feſtival kept in honour of Ceres, every fourth, by ſome ſtates, but by others, every fifth year. The Athenians celebrated it at Eleuſis, a town of Attica, whence the name.

ELEUTHERIA, another feſtival celebrated at Platæa, by delegates from almoſt all the cities of Greece, in honour of Jupiter Eleutherius, or the aſſertor of Liberty.

ELIQUATION, in metallurgy, a ſeparation of the different parts of mixed bodies, by the different degrees of fire required to melt them.

ELIRE, or CONGE D'ELIRE. See the article CONGE.

ELISIUM, or ELYSIUM. See ELYSIUM.

ELISION, in grammar, the cutting off or ſuppreſſing a vowel at the end of a word, for the ſake of ſound, or meaſure, the next word beginning with a vowel.

Eliſions are pretty frequently met with in Engliſh poetry, but more frequently in the Latin, French, &c. They chiefly conſiſt in ſuppreſſions of the *a*, *e*, and *i*, though an eliſion ſuppreſſes any of the other vowels: in the following example from Virgil there are three eliſions.

Phillida amo ante alias. ——

ELIXATION, in pharmacy, the extracting the virtues of ingredients by boiling or ſtewing. See DECOCTION.

ELIXIR, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir ſeems to conſiſt in this, that a tincture is drawn from one ingredient, ſometimes, with an addition

Engine for Extinguishing Fires

Fig. 4.

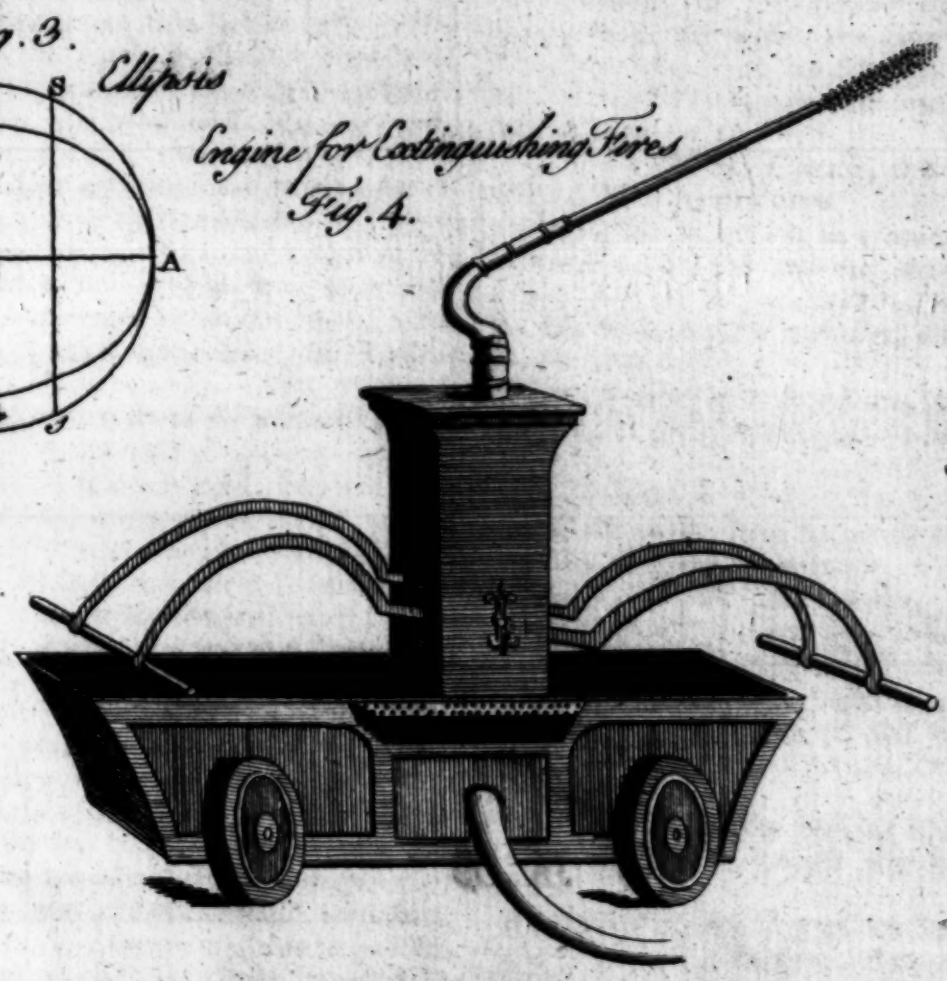

Fig. 6. Engine.

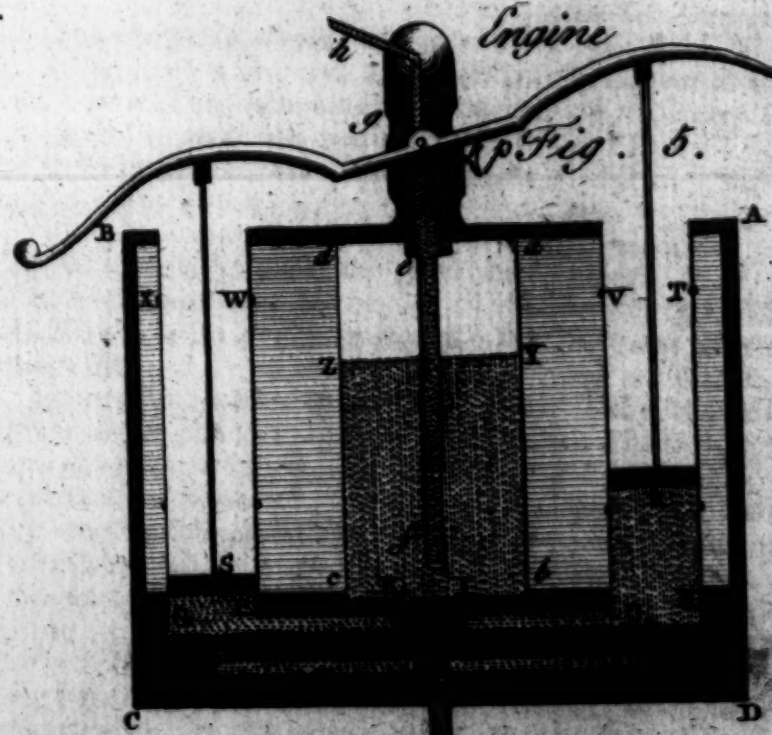

Engine

Fig. 5.

addition of another to open it, and diſpoſe it to yield to the menſtruum; whereas an elixir is a tincture extracted from ſeveral ingredients at the ſame time.

The word is Arabic, *al-eciſir*, or *al-ekſir*, and implies an artificial extraction of ſome eſſence.

ELK, *Alce*, in zoology, an animal of the deer-kind, with the horns palmated, and without a ſtem. It is a native of the northern parts of Europe; and is a very large and ſtrong animal, being equal in ſize to a horſe, but much leſs beautiful.

Elk's hoofs ſtand recommended for the cure of the epilepſy, but at preſent are only uſed as an ingredient in ſome old compoſitions.

ELL, *Ulna*, a meaſure of length, different in different countries; but thoſe moſtly uſed in England, are the Engliſh and Flemiſh ells; the former of which is three feet nine inches, or one yard and a quarter, and the latter only twenty-ſeven inches, or three quarters of a yard. In Scotland, the ell contains 37 $\frac{2}{10}$ Engliſh inches. See the article MEASURE.

ELLIPSIS, or ELLIPSE, in geometry, a figure produced from the ſection of a cone, vulgarly called an oval. See CONIC *Sections*.

The word is Greek, ελλειπσις, and derived from ελλειπω, to want or be deficient; becauſe its conjugate is leſs than its tranſverſe diameter.

If the tranſverſe diameter of an ellipſis, as T S (plate LXI. *fig.* 1.) be interſected or divided into any two parts by an ordinate rightly applied; as at the points A, C, *a*, &c. then are thoſe parts, T A, T C, T *a*, and S A, S C, S *a*, &c. uſually called abſciſſæ's (which ſignifies lines or parts cut off), and by the rectangle of any two abſciſſæ's, is meant the rectangle of ſuch two parts, as, being added together, will be equal to the tranſverſe diameter:

As T A + S A = T S. And T C + S C = T S.
Or, T *a* + S *a* = T S, &c.

Every ellipſis is proportioned, and all ſuch lines as relate to it are regulated, by the help of the following general theorem:

As the rectangle of any two abſciſſæ's: is to the ſquare of half the ordinate which divides them:: ſo is the rectangle of any two abſciſſæ's: to the ſquare of half that ordinate which divides them;

That is, T A × S A : B A *q* :: T *a* × S *a* : *b aq*. T A × S A : B A *q* :: T C × S C : N C *q*. T C × S C : N C *q* :: T *a* × S *a* : *b aq*, &c.

Theſe proportions being found to be the true and common properties of every ellipſis, all that is further required in, or about, that ſection, may be eaſily deduced from them.

There are ſeveral ways of finding the latus rectum; but, I think, none ſo eaſy, and ſhews it ſo plainly to be the third principal line in the ellipſis, as the following theorem:

As the tranſverſe diameter: is in proportion to the conjugate:: ſo is the conjugate: to the latus rectum, viz.

T S : N *n* :: N *n* : L R, the latus rectum. *fig.* 2.

From hence it is evident, that L R, thus formed, is that ordinate by which the other ordinates may be regulated and found: therefore, it is the latus rectum.

Hence it follows, that if the tranſverſe and conjugate diameters of any ellipſis are given (either in lines or numbers) the latus rectum may be eaſily found; and then any ordinate, whoſe diſtance from the conjugate is given, may be found.

The focus of an ellipſis is the diſtance of the latus rectum from the conjugate or middle of the ellipſis, and that diſtance is always a mean proportional between the half ſum and the half difference of the tranſverſe and conjugate diameters, which gives this theorem:

From the ſquare of half the tranſverſe, ſubtract the ſquare of half the conjugate; the ſquare root of their difference will be the diſtance of each focus from the middle, or common center of the ellipſis.

That is, ſuppoſing the points *f* and F to be the true focus's, viz. *f* C = C F, and T C = $\frac{1}{2}$ T S. N C = $\frac{1}{2}$ N *n*. Then T C + N C : *f* C :: F C : T C − N C. Therefore, F C *q* = T C *q* − N C *q*. Conſequently, F C = $\sqrt{\text{T C}q - \text{N C}q}$. Now from hence is produced that notable propoſition, upon which is grounded the uſual method of deſcribing an ellipſis, and drawing of tangents, &c.

If from the two focus's of any ellipſis there be drawn two right-lines, ſo as to meet each other in any point of the ellipſis's periphery, the ſum of theſe lines will be equal to the tranſverſe.

Viz. *f* N + N F = T S. *f* L + L F = T S. Or F B + B F = T S, &c.

And this propoſition muſt needs hold true, for every point in the ellipſis periphery, viz. at B, &c. as will evidently appear to any one who rightly conſiders, that as a thread juſt the length of the diameter of any circle, having its two ends tied together, and then moved about a point in the center (viz. by making it a double radius) will, by drawing another point in its extremity, deſcribe the periphery of a circle. Even ſo, if a thread, juſt the length of the tranſverſe diameter T S, have its two ends ſo fixed upon the two focus's *f* and F, as that it may be moved about them, by drawing a point in its extremity, (viz. at its full ſtretch) it will deſcribe the true periphery of an ellipſis.

Let A B (*fig.* 3.) be the tranſverſe diameter of the ellipſis A F B G, G F its conjugate diameter, A B D E the circumſcribing circle,

Becauſe in the circle A C × C B : A P × P B :: C D *q* : P N *q*; and in the ellipſis A C × C B : A P × P B :: C E *q* : P M *q*, it will be C D : C F :: P N : P M; or, as (E D =) A B : F G :: N R : M Q; but all the N R's make the circle, and the ſame number of M Q's make the ellipſis. Hence, as A B to F G, or as the longeſt diameter of the ellipſis to its ſhorteſt, ſo is the area of the circumſcribing circle to the area of the inſcribed ellipſis; that is, as A B : F G :: area of the circle, to the area of the ellipſis. Wherefore, as (A B × A B =) A B *q* : A B × F G :: circle's area, to the elliptical area.

Hence, as the circle is to its circumſcribed ſquare, or to the ſquare of its diameter; ſo is the ellipſis to the circumſcribing parallelogram, or to the rectangle of its diameter.

Hence the quadrature of the ellipſis depends upon the quadrature of the circle.

Hence alſo the area of any ſegment of the ellipſis is to the area of the correſponding circular ſegment, as the ſhorteſt diameter of the ellipſis to the longeſt.

Hence as 4, to 3,14159,26536—, or as 1, to .78539,81634, ſo is the product of the diameters of the ellipſis to its area. Wherefore, if the product of the diameters of an ellipſis be multiplied by .78539,81634, the laſt product will give its area.

ELLIPSIS, in grammar and rhetoric, is a figurative way of ſpeaking by which ſome word in a diſcourſe is retrenched, or omitted, when ſome violent paſſion will not let a perſon utter what he thinks.

ELLIPTIC, or ELLIPTICAL, ſomething belonging to an ellipſis. See ELLIPSIS.

ELLIPTICAL ARCH, a part or ſegment of the curve of an ellipſis.

Elliptical arches are frequently preferred to thoſe that are circular in various kinds of buildings, becauſe their ſpan may be equal to thoſe of the circle, without riſing to ſo great a height; and this is the reaſon why they have been preferred in bridges: but it muſt be remembered that they will decreaſe in ſtrength, in proportion as they deviate from the circle. See the article BRIDGE.

The manner of conſtructing the centers of elliptical arches will be ſufficiently evident from the figures on plate LX. if the nature and properties of the ellipſis be previouſly known. See ELLIPSIS.

Explanation of plate LX.

Fig. 1. is the center that was uſed to ſupport the vault of St. Peter's church at Rome. This vault is nearly circular.

Fig. 2. is a center of an elliptical arch for ſupporting the arch of a bridge, arcade, vault, &c.

Fig. 3. is another elliptical center lower, but of equal ſpan with that of *fig.* 2.

Fig. 4. is another center for ſupporting the vouſoirs of a vault, &c. conſiderably lower than the former.

The centers are compoſed of the following pieces of timber.

A, triangular braces.
B, perpendicular or upright beams.
C, tranſverſe or horizontal beams.
D, ſide-braces.
d, ſupporting-braces.
E, under-tranſverſe-beams.
F, jambs or ſide-pieces for ſupporting the triangular-beams.
G, large ſide-braces.
g, ſmall ſide-braces.
H, braces.
I, under-braces.
K, under-ſide-braces.
L, under-triangular-braces.
M, ſupporting-pieces.
N, curve-pieces.
P, vouſoirs.
Q, horizontal pieces of wood that ſupport the carpentry.
R, piles.
S, a ſmall pier of maſonry.

ELLIPTOIDES, in geometry, a name uſed by ſome to denote infinite ellipſes, defined by the equation $a y^{m+n} = b x^m (a - x^n)$.

There are ſeveral ſpecies of elliptoides; as for inſtance, if $a y^3 = b x^2 (a - x)$ it is a cubical elliptoid; and if $a y^4 = b x^2 (a - x^2)$ it denotes a biquadratic elliptoid, which is an ellipſis of the third order, with reſpect to the Apollonian ellipſis.

ELM, *Ulmus*, in botany, a genus of trees, whoſe characters are the following.

The flower conſiſts of one leaf, which is ſhaped like a bell, having many ſtamina, or threads, in the center: from the bottom ariſes the pointal, which afterwards becomes a membranaceous or leafy fruit, almoſt heart-ſhaped; in the middle of which is placed a pear-ſhaped ſeed veſſel, containing one ſeed, for the moſt part of the ſame ſhape.

Theſe trees are very proper to plant in hedge-rows, upon the borders of fields, where they will thrive much better than when planted in a wood, or cloſe plantation; and their ſhade will not be very injurious to whatever grows under them; but when theſe trees are tranſplanted out upon banks after this manner, the banks ſhould be well wrought and cleared from all other roots, otherwiſe the plants, being taken from a better ſoil, will not make much progreſs in theſe places. About Michaelmas will be a good time for this work, for the reaſon before aſſigned; but when they are planted, there ſhould be ſome ſtakes fixed in by them, to which they ſhould be faſtened, to prevent their being diſplaced by the winds; and part of their heads ſhould be taken off, before they are planted, which will alſo be of uſe in preventing their being eaſily overturned by winds; but by no means ſhould their leading ſhoot be ſtopped; nor their branches too cloſely cut off; for, if there are not ſome ſhoots left to draw and attract the ſap, they will be in danger of miſcarrying.

In planting of theſe trees, great care ſhould be taken not to bury their roots too deep; which is very injurious to them, eſpecially if they are planted on a moiſt loam or clay; in which caſe, if the clay is near the ſurface, it will be the beſt way to raiſe the ground in an hill, where each tree is to be planted, which will advance their roots above the ſurface of the ground, ſo that they will not be in danger of rotting in winter with moiſture.

When theſe trees are propagated by ſuckers taken from the foot of old trees, they are commonly laid into the ground very cloſe in beds, where, in dry weather, they may be frequently watered, to encourage their putting out roots. In theſe beds they are left two years; by which time thoſe that live will be well rooted, though a great many of them generally die; then they ſhould be tranſplanted into the nurſery.

The timber of the common Engliſh elm is generally preferred to the reſt; though that of the witch elm is often as good, and is the largeſt tree, when planted on a kindly ſoil: but the Dutch elm affords the worſt timber, and never will grow to the ſtature of either of the other ſorts; ſo that this ſhould not be cultivated for the timber; therefore the beſt way to be ſure of the kinds which a perſon would chooſe to propagate, is to have a nurſery of ſtools, in order to furniſh layers; for when they are grubbed up from hedge-rows, there will often be many ſorts intermixed, eſpecially if the people who go about to gather them, furniſh them; becauſe they take them indifferently, wherever they can procure them; ſo that when they are planted out thus blended together, there will be a conſiderable difference in their growths, which will deface the plantation.

ELOCUTION, in rhetoric, the adapting words and ſentences to the things or ſentiments to be expreſſed. It conſiſts in elegance, compoſition, and dignity. The firſt, comprehending the purity and perſpicuity of a language, is the foundation of elocution. The ſecond ranges the words in proper order; and the laſt adds the ornaments of tropes and figures to give ſtrength and dignity to the whole. See STYLE, PERIOD, FIGURE, &c.

ELOGY, *Elogium*, a praiſe or panegyric beſtowed on any perſon or thing, in conſideration of its merit. The beauty of elogy conſiſts in an expreſſive brevity. Elogiums ſhould not have ſo much as one epithet properly ſo called, nor two words ſynonymous. They ſhould ſtrictly adhere to truth; for extravagant and improbable elogies rather leſſen the character of the perſon or thing they would extol.

ELOHA, in Scripture, the ſingular of Elohi, one of the names of God.

ELOHI, ELOI, or ELOHIM, in Scripture, one of the names of God. But it is to be obſerved, that angels, princes, great men, judges, and even falſe gods, are ſometimes called by this name. The ſequel of the diſcourſe is what aſſiſts us in judging rightly concerning the true meaning of this word. It is the ſame as Eloha, one being the ſingular, and the other the plural. However, Elohim is often conſtrued in the ſingular number, particularly when the true God is ſpoken of; but when falſe gods are ſpoken of, it is conſtrued rather in the plural.

ELONGATION, in aſtronomy, is the removal of a planet to the fartheſt diſtance it can be from the ſun, as it appears to an eye placed on the earth.

The word is Latin, from *elongo*, to be diſtant from.

The utmoſt elongation of Venus can be but 45 degrees, and that of Mercury but 30 degrees; which is the reaſon this planet is ſo rarely ſeen.

ELOPEMENT, in law, is where a married woman departs from her huſband, and cohabits with an adulterer; in which caſe the huſband is not obliged to allow her any alimony out of his eſtate, nor is he chargeable for neceſſaries for her of any kind. However, the bare advertiſing a wife in the Gazette, or other public papers, is not a legal notice to perſons in general not to truſt her; tho' a perſonal notice given by the huſband to particular perſons, is ſaid to be good.

An action lies, and large damages may be recovered, againſt a perſon for carrying away and detaining another man's wife.

ELOQUENCE, the art of ſpeaking well, ſo as to affect and perſuade.

Cicero defines it the art of ſpeaking with copiouſneſs and embelliſhment.

Eloquence and rhetoric differ from each other, as the theory from the practice; rhetoric being the art which deſcribes the rules of eloquence, and eloquence that art which uſes them to advantage. For the moſt part, however, they are uſed indiſcriminately for each other.

ELUL, one of the Hebrew months, anſwering pretty nearly to our Auguſt. There are but twenty-nine days in it. It is the twelfth month of the civil year, and the ſixth of the eccleſiaſtical. Upon the ſeventh or ninth day of this month the Jews faſt, in memory of what happened after the return of thoſe who went to view the promiſed land.

ELUTRIATION, in metallurgy, the ſeparating the lighter matters from the mixed ores of metals, by means of great quantities of fair water.

ELYSIUM, or ELYSIAN FIELDS, in heathen mythology, certain plains abounding with woods, fountains, verdure, and every delightful object; ſuppoſed to be the habitation of heroes and good men, after death.

According

T. Lodge Sculp.

5 1A 59

According to ſome, the fable of elyſium is of Phœnician extraction, or rather founded upon the account of Paradiſe delivered in the Scriptures. As to the ſituation of theſe happy regions, authors are not agreed. Homer makes them the ſame with certain pleaſant meadows near Memphis, on the banks of the Acheruſian lake, mentioned by Diodorus Siculus, in his deſcription of the funerals of the Egyptians. Virgil ſeems to place them in Italy, only under ground; and others in other places: but the generality of authors will have them to be ſituated in the Fortunate Iſlands.

ELYTROIDES, or VAGINALIS, in anatomy, the ſecond proper membrane that involves the teſtes. See TESTICLE.

EMANCIPATION, in the Roman law, the ſetting free a ſon from the ſubjection of his father; ſo that whatever moveables he acquires, belong in propriety to him, and not to his father, as before emancipation.

EMARGINATED, among botaniſts, an appellation given to ſuch leaves as have a little indenting on their ſummits: when this indenting is terminated on each ſide by obtuſe points, they are ſaid to be obtuſely emarginated; whereas when theſe points are acute, they are called acutely emarginated.

EMAUX DE L'ESCU, in heraldry, the metal and colour of the ſhield or eſcutcheon. See the article SHIELD.

EMBALMING is the opening a dead body, taking out the inteſtines, and filling the place with odoriferous and deſiccative drugs and ſpices, to prevent its putrifying.

EMBARGO, in commerce, an arreſt on ſhips, or merchandize, by public authority; or a prohibition of ſtate, commonly on foreign ſhips, in time of war, to prevent their going out of port; ſometimes to prevent their coming in; and ſometimes both for a limited time.

EMBASSADOR, or AMBASSADOR. See AMBASSADOR.

EMBASSY, the office or function of an ambaſſador.

EMBATTLED, in heraldry, the ſame with crenelle. See CRENELLE.

EMBER-WEEKS, or DAYS, in the Chriſtian church, are certain ſeaſons of the year ſet apart for the imploring God's bleſſing, by prayer and faſting, upon the ordinations performed in the church at ſuch times.

Theſe ordination-faſts are obſerved four times in the year, viz. the Wedneſday, Friday, and Saturday after the firſt Sunday in Lent, after Whit-Sunday, after the fourteenth of September, and the thirteenth of December; it being enjoined, by a canon of the church, that deacons and miniſters be ordained, or made, only upon the Sundays immediately following theſe ember-faſts.

The ember-weeks were formerly obſerved in different churches with ſome variety, but were at laſt ſettled as they are now obſerved, by the council of Placentia, in the year 1095. The council of Mentz, convened by Charlemagne, mentions the ember-weeks as a new eſtabliſhment.

EMBLEM is a kind of painted ænigma, or certain figures delineated or cut metaphorically, expreſſing ſome action, with reflections underneath, which in ſome meaſure explain the ſenſe of the device, and at the ſame time inſtruct us in ſome moral truth, or other matter of knowledge.

The word is derived from the Greek, εμβαλλω, to throw upon.

The emblem is ſomewhat plainer than the ænigma. The Greeks gave this name to inlaid or Moſaic works, and even to all kinds of ornaments of vaſes, garments, &c. and the Latins uſed emblem in the ſame ſenſe. The invention of emblems is certainly modern; they were entirely unknown to the ancients.

EMBLEMENTS, among lawyers, denote the profits of ſown lands; but are ſometimes uſed, more largely, for any products that naturally ariſe from the ground.

EMBOLISMIC, intercalary, or belonging to the emboliſmus.

The word is derived from the Greek, εμβαλλω, to inſert or put in.

EMBOLISMUS, the exceſs of the ſolar year above the lunar, whereby the lunations happen every ſubſequent year eleven days ſooner than in the foregoing, which, when they amount to thirty days, make a new month, called the emboliſmical lunation, or emboliſmatical month; which muſt be added to make the common lunar year equal to the ſolar.

EMBOLUS, the moveable part of a pump, or ſyringe, called alſo the piſton, or ſucker. See the article PISTON, PUMP, SYRINGE, &c.

EMBOSSING, or IMBOSSING, in architecture and ſculpture, the forming or faſhioning works in relievo, whether cut with a chiſſel, or otherwiſe.

EMBRACE *the Volt*, in the manege. A horſe is ſaid to embrace a volt when, working upon volts, he makes a good way every time with his fore-legs.

EMBRACEOR, among lawyers, a perſon who, having received a reward ſo to do, comes to the bar with one of the parties, and ſpeaks in the caſe; or privily labours the jury, or ſtands in court to over-look them, whereby they are awed or put in fear. Actions of this kind will be embracery, whether the jurors give verdict on the ſide of the party or not. The penalty of this offence is twenty pounds, and impriſonment of the party at the diſcretion of the court: and may be proſecuted either by indictment at common law, as well as by action on the ſtatute. But attorneys and other lawyers are excepted.

EMBRASURE, in architecture, the enlargement made of the aperture of a door or window on the inſide of the wall; its uſe being to give the greater play for the opening of the door, or caſement, or to admit the more light. When the wall is very thick, they ſometimes make embraſures on the outſide.

EMBRASURE, in fortification, a hole or aperture in a parapet, through which the cannon are pointed to fire into the moat or field.

Embraſures are generally twelve feet diſtant from one another, every one of them being from ſix to ſeven feet wide without, and about three within: their height above the platform is three feet on that ſide towards the town, and a foot and a half on the other ſide towards the field; ſo that the muzzle may be ſunk on occaſion, and the piece brought to ſhoot low.

EMBROCATION, in ſurgery and pharmacy, an external kind of remedy, which conſiſts in an irrigation of the part affected, with ſome proper liquor, as oils, ſpirits, &c. by means of a woollen or linen cloth, or a ſponge, dipped in the ſame.

The uſe of embrocation is either to attenuate and diſlodge ſomething obſtructed underneath the ſkin, to eaſe pains, or to irritate the part into more warmth and a quicker ſenſe of feeling.

The pumping uſed in natural baths is properly an embrocation.

EMBROIDERY, a work in gold, or ſilver, or ſilk thread, wrought by the needle upon cloth, ſtuffs, or muſlin, into various figures. In embroidering ſtuffs, the work is performed in a kind of loom, becauſe the more the piece is ſtretched, the eaſier it is worked.

EMBRYO, in phyſiology, the firſt rudiments of an animal in the womb, before the ſeveral members are diſtinctly formed; after which period it is denominated a fœtus. See the articles CONCEPTION, GENERATION, and FOETUS.

EMBRYO-PLANT, the ſame with plantula ſeminalis. See the article PLANTULA.

EMBRYOTHLASTES, in midwifery, an inſtrument contrived for breaking the bones, for the more eaſy extraction of the fœtus, in difficult labours.

EMBRYOTOMY, the cutting a fœtus to pieces whilſt in the womb, practiſed in caſes of neceſſity, when there is no other way of ſaving the mother.

EMBRYULCUS, a hook for extracting the child in difficult labours.

EMERALD, *Smaragdus*, in natural hiſtory, the moſt beautiful of all the claſs of coloured gems, when perfect. It is found ſometimes in the roundiſh or pebble form, ſometimes in the columnar or cryſtalline one; the pebble emeralds, however, are the moſt valued; there are multitudes found of the ſize of a large pin's head, for one of any tolerable bigneſs; though now and then there occur ſtones

of the ſize of a horſe-bean, and even up to that of a walnut, though this laſt very rarely. The pebble emeralds are found looſe in the earth of mountains, and in the beds of rivers; the cryſtalliform ones are uſually met with adhering to a white, opaque, cryſtalline matter, though ſometimes to pieces of jaſper or of the praſius, a coarſer and ſofter gem of the ſame colour, only with ſome tinge of a yellowiſh caſt, and called the root of the emerald. The pebble emeralds are in their natural ſtate bright and tranſparent, though leſs gloſſy than the columnar ones; both are always of a perfect and pure green. It has this green in all the different ſhades, from very dark to extremely pale, and is probably ſometimes entirely colourleſs, though then the Engliſh jewellers call it white ſapphire.

Emeralds are found in the Eaſt-Indies, and in many parts of America, particularly about the gold mines of Peru; they are alſo met with in Sileſia, Bohemia, and in ſome other parts of Europe; but they are very different in luſtre and value, as they come from theſe different parts. The Oriental emeralds are of equal hardneſs with the ſapphire; thoſe of Peru are of much the ſame hardneſs with the garnet, and therefore of proportionably leſs beauty than the Oriental; as to thoſe of the ſeveral parts of Europe, they are but little harder than the cryſtal; but when they are not harder than that ſtone, they are not emeralds at all, but only cryſtals tinged green by copper, and uſually found in mines of that metal. Theſe are very beautiful, but vaſtly inferior to the very worſt of emeralds in hardneſs. The Oriental emeralds are at preſent found only in Cambay, and are there very ſcarce, and few of late have been imported into Europe; the princes of that part of the world being themſelves very fond of them: large quantities of the fineſt emeralds in the world are to be ſeen among their regalia. What we ſee at the Engliſh jewellers under the name of Oriental emeralds are all from Peru, and many of them very beautiful; they are found in the mountains over the gold mines, among a duſky greyiſh earth that fills up the perpendicular fiſſures of the ſtrata of the earth, and ſometimes adhering to the ſides of thoſe fiſſures in their cryſtalline ſhape.

The ſmaragdus of the ancients, properly ſo called, was evidently the ſame with our emerald; though they comprehended alſo under this name every gem, or even ſtone of any conſiderable beauty, and of a green colour.

The emerald is of the number of thoſe gems that owe their colour to the metalline ſulphurs; and therefore loſe it in the fire, becoming colourleſs as cryſtal; though ſtill very hard and of a fine luſtre. The Engliſh druggiſts ſell us, under the name of this gem, fragments of coloured cryſtals and ſpars, which are found in abundance about the mines of copper and iron. It is very certain indeed that the emerald owes its colour to the former of theſe metals, becauſe the factitious paſtes or glaſſes may be coloured to a true ſmaragdine hue by copper; but it does not follow that all the green cryſtals and ſpars have the particles of the ſame metal in the ſame proportion, or that they have not alſo other particles very improper to be given internally.

It will ſtop hæmorrhages and diarrhœas, and ſweeten or obtund the too acrid humours: but as this is recorded of the emerald, as found among the druggiſts, it belongs rather to the cryſtal than to the gem. And perhaps it would be better for the world if both this and the other fragments of the gems were baniſhed from the compoſitions in which they are ordered, and common cryſtal uſed in their ſtead.

To counterfeit EMERALDS. Take of natural cryſtal, four ounces; of red lead, four ounces; verdigriſe, forty-eight grains; crocus martis, prepared with vinegar, eight grains; let the whole be finely pulveriſed and ſifted; put this into a crucible, leaving one inch empty; lute it well, and put it into a potter's furnace, and let it ſtand there as long as they do their pots. When cold, break the crucible, and you will find a matter of a fine emerald-colour, which, after it is cut and ſet in gold, will ſurpaſs in beauty an Oriental emerald.

EMERGENT YEAR, in chronology, the ſame with epocha, whence any æra, or method of reckoning time, commences: ſuch is that of the creation of the world, of the birth of our Saviour, &c. See the article EPOCHA.

EMERSION, in philoſophy, is the riſing of any ſolid above the ſurface of a fluid, eſpecially lighter than itſelf, into which it had been violently immerged or thruſt.

EMERSION, in aſtronomy, is the time when any planet that is eclipſed, begins to emerge or get out of the ſhadow of the eclipſing body.

EMERUS, *Scorpion Sena*, in botany, a genus of plants, whoſe characters are as follow.

It hath leaves like thoſe of the colutea: the flowers are papilionaceous: the pods are ſlender, and contain two or three cylindrical ſhaped ſeeds in each.

Theſe ſhrubs are eaſily propagated by ſowing their ſeeds, which they commonly produce in great plenty, in March, upon a bed of light ſandy earth, obſerving to keep the bed clear from weeds; and in very dry weather you muſt often refreſh the bed with water, which ſhould be given carefully, leſt the ſeeds ſhould be waſhed out of the ground by haſty watering. When the plants are come up, you muſt continue the ſame care; and the Michaelmas following, if your plants have thriven well, you may draw out the largeſt; which may be tranſplanted into the nurſery, at three feet diſtance row from row, and a foot aſunder in the rows. This will give room to thoſe plants which are left to grow in the ſeed bed; in which place they may remain another year, when they will alſo be fit to tranſplant into a nurſery; where they ſhould be trained up in the manner you deſign them to grow, either in round heads, or in rude plants. In one or two years more they will be fit to plant out, where they are to remain for good: in doing of which you ſhould be careful, in taking them up, not to break or wound their roots; nor ſhould they remain too long in the nurſery before they are tranſplanted; for they are ſubject to ſhoot downright roots, which, when cut off, oftentimes prove the death of the tree. In all other reſpects it muſt be treated like other flowering ſhrubs; amongſt which, this is commonly ſold at the nurſeries. It delights in a dry ſoil, and may alſo be propagated by laying down the tender branches; which take root in about a year's time, and may then be tranſplanted into a nurſery, and managed in the ſame manner as the ſeedings. *Miller's Gard. Dict.*

EMERY, *Smiris*, *Smerillus*, *Smyrites*, ſo called from σμαω, or σμεω, to cleanſe or poliſh, a ſpecies of ſtone of which there are three ſorts mentioned by authors; a golden, a cupreous, and a ferrugineous emery. The golden emery is ſaid to be found in the Peruvian and other American mines, to be of a reddiſh colour, to have ſmall veins or ſpecks of gold and ſilver imbeddded in it, to be very rare, and its exportation to be prohibited by the king of Spain: the cupreous ſort to be likewiſe reddiſh, but more equal and free from veins, to hold no gold or ſilver, and to be found in copper mines in Europe: the ferrugineous, to be of a ſparkling whitiſh, a dark grey, or a blackiſh colour, to be found in rich iron mines, and to be the leaſt valuable ſort.

The common emery, whatever be its colour, whether reddiſh, greyiſh, or blackiſh, is a compact ſtone, ſo hard as to cut glaſs like the diamond; impregnated with iron, and a very ſmall portion of copper. It is met with in Norway, Sweden, England, Saxony, and other countries. Bruckman relates, that the emery found at St. Georgenſtadt in Miſnia is ſuperior to the Spaniſh. It is uſed for cutting and poliſhing precious ſtones, for poliſhing agate, porphyry, marble, glaſs, metalline ſpecula, iron and ſteel, and the various utenſils and ornaments made of theſe kinds of ſubſtances: for theſe purpoſes the emery is ground in mills, the powder paſſed through ſieves of different degrees of fineneſs, and thus divided into different ſortments, the fineſt of which, for the nicer uſes, are further divided by waſhing them over ſeveral times with water. The refuſe emery, in grinding, or ſuch as has been uſed in poliſhing, is, in France, dried and kept apart, under the name of *potée d'emery*. Some have employed powdered emery, from its power of poliſhing hard ſtones, as a dentifrice: but for this uſe it is by no means proper, as it wears off the natural poliſh of the teeth.

Several attempts have been made to melt this mineral with the ſeveral fluxes uſed in aſſays for iron, as alkaline

ſalt,

ſalt, borax, charcoal duſt, pitch, tallow, &c. but a fire ſufficiently ſtrong to conquer the refractory ſtony matter, could never be procured. Emery in its crude ſtate is not affected by the magnet. All acids extract ſomewhat from the emery, but none of them diſſolve one half of it.

Putty of EMERY, a kind of dirty matter found on the lapidaries wheels, containing part of the powder of emery.

EMETICS, *Emetica*, are medicines which induce vomiting.

The word is derived from the Greek, εμεω, to vomit.

Emetics are either mild and gentle, or of a more ſtrong and draſtic quality. The milder ſort were principally uſed by the ancients, ſince they are ſafe, and generally, by their quantity, ſtimulate the ſtomach to vomit, eſpecially when it is weak. But theſe do not act beyond the limits of the ſtomach, from which they very advantageouſly evacuate crude, phlegmatic, and bilious humours, produced by improper aliments, or a bad digeſtion.

The more ſtrong and draſtic emetics, when exhibited in a ſmall doſe, by their fine, cauſtic, ſalino-ſulphureous acrimony, act not only on the nervous coat of the ſtomach and inteſtines, by ſpaſmodically conſtricting them; but if exhibited in a ſomewhat larger doſe, they penetrate beyond the ſtomach, into the highly nervous biliary ducts, into the glands of the inteſtines, meſentery, and pancreas, as alſo into the liver, and expel their contained humours from theſe parts. Sometimes alſo they affect the whole nervous ſyſtem, and prove highly injurious to the conſtitution.

It is proper, in order to make emetics work more eaſily, to exhibit them always in a liquid form, or in a ſufficient quantity of ſome moiſtening, relaxing, and pinguious vehicle: for vomiting not only requires a powerful conſtriction of the pylorus and bottom of the ſtomach, but alſo a relaxation of the ſuperior orifice of the œſophagus.

Sydenham lays it down as a rule, that whenever a vomit and bleeding are neceſſary, bleeding ſhould always precede the exhibition of an emetic.

Common ſalt is uſed to check the operation of emetics; which it will certainly do, and make them run off by ſtool: violent vomitings are alſo ſtopped by copious draughts of warm diluting fluids, by mild oils, by opiates, aromatics, by grateful acids, and corroborating medicines, either taken internally, or applied externally to the region of the ſtomach.

EMETOLOGY, that part of medicine which treats of emetics.

The word is formed from the Greek, εμετος, a vomit, and λογος, a diſcourſe.

EMINENCE, a title of honour peculiar to cardinals. See the article CARDINAL.

EMINENCE, in the military art, a high or riſing ground, which overlooks and commands the low places about it: ſuch places within cannon-ſhot of a fort, are a great diſadvantage; for if the beſiegers become maſters of them, they can, from thence, fire into the fort.

EMINENTIAL EQUATION, an artificial equation, containing another equation eminently: it is ſometimes uſed in the inveſtigation of the areas of curved-lined figures. See EQUATION.

EMISSARY, in a political ſenſe, a perſon employed by another to ſound the opinions of people, ſpread certain reports, or act as a ſpy over other people's actions. See the article SPY.

EMMENAGOGUES, EMMENAGOGA, in phyſic, are medicines which promote the menſes or monthly courſes.

The word is derived from the Greek, εμμηνια, the menſtrual diſcharge, and αγω, to draw, or force.

Emmenagogues do this, either by giving a greater force to the blood in its circulation, whereby its momentum againſt the veſſels is increaſed; or by making it thinner, whereby it will more eaſily paſs through any outlets. The former intention is helped by chalybeates and all other ſubſtances of the like gravity and elaſticity; and this is the caſe of a leuco-phlegmatic habit, or the green ſickneſs and its cure: but in the latter caſe, where the blood is florid and too high, attenuating alteratives and detergents are the only remedies, becauſe they are fitteſt to carry the blood through thoſe little apertures deſtined for its diſcharge into the uterus. *Quincy.*

EMOLLIENTS are ſuch medicines as ſheathe and ſoften the aſperities of the humours, and relax and ſupple the ſolids at the ſame time.

The word is derived from the Latin *emollio*, to ſoften.

Their effects may be thus accounted for; by what means ſoever the juices in the human body have obtained any ſharpneſs, ſo as to vellicate the fibres and nervous parts, as is often the caſe; thoſe things which are ſmooth, ſoft, and yielding, cannot but wrap up the points and render them imperceptible; whereby they may be gradually, by the courſe of circulation, brought to ſome proper emunctory, without doing any injury by the way. Such ſharp particles likewiſe draw the fibres into ſpaſms, keep them too tenſe, and frequently occaſion thereby obſtructions of the worſt kind. In all ſuch caſes, therefore, emollients lubricate and moiſten the fibres, ſo as to relax them into their proper dimenſions, whereby ſuch diſorders ceaſe. *Quincy.*

EMPASTING, or IMPASTING, in painting, is the laying on of colours thick and bold, or the applying ſeveral lays of colours, ſo as they may appear thick.

The term is alſo uſed when the colours are laid diſtinct and aſunder, and not ſoftened or loſt in each other. See the article COLOURING.

EMPATTEMENT, in fortification, the ſame with talus. See the article TALUS.

EMPERESS, or EMPRESS, denotes either the wife of an emperor, or a woman who governs ſingly an empire, in her own right.

EMPEROR, *Imperator*, a title of honour among the ancient Romans, conferred on a general who had been victorious, and now made to ſignify a ſovereign prince, or ſupreme ruler of an empire.

EMPETRUM, berry-bearing-heath, in botany, a genus of plants, the flower of which conſiſts of three petals, of an oval oblong figure: the ſtamina are three very long capillary filaments: the fruit is a globoſe, depreſſed, and unilocular berry, containing nine ſeeds, gibbous on one ſide, and angulated on the other.

EMPHASIS, in rhetoric, a particular ſtreſs of the voice and action, laid on ſuch parts or words of the oration, as the orator wants to enforce upon his audience. See ACCENT.

EMPHYSEMA, in phyſic, is any flatulent tumour, generally taken for a ſoft one, ariſing from air that is contained in the cells of the membrana celluloſa.

The word is Greek, from εν and φυσαω, to inflate.

EMPIRE, *Imperium*, in political geography, a large extent of land, under the juriſdiction or government of an emperor. See the article EMPEROR.

EMPIRIC, an appellation given to thoſe phyſicians who conduct themſelves wholly by their experience, without ſtudying phyſic in a regular way. Some even uſe the term, in a ſtill worſe ſenſe, for a quack who preſcribes at random, without being at all acquainted with the principles of the art.

EMPLASTER, *Emplaſtrum*, in pharmacy, the ſame with plaſter. See PLASTER.

EMPYEMA, in phyſic, is, ſtrictly ſpeaking, a collection of purulent matter, in any part whatſoever; but it generally ſignifies that in the cavity of the breaſt only; and which ſometimes happens upon the opening of abſceſſes, or ulcerations of the lungs, or membranes incloſing the thorax.

The word is derived from the Greek, εν, and πυον, purulent matter.

EMPYREUM, a term uſed by divines for the higheſt heaven, where the bleſſed enjoy the beatific viſion.

EMPYREUMA, among chemiſts and phyſicians, the fiery taſte or offenſive ſmell which brandies, and other bodies prepared by fire, are impregnated with.

EMRODS, or HÆMORRHOIDS. See the article HÆMORRHOIDS.

EMULGENT, or RENAL ARTERIES, thoſe which ſupply the kidneys with blood; being ſometimes ſingle, ſometimes double on each ſide. See ARTERY.

EMULSION, in pharmacy, properly ſignifies medicines which reſemble milk. Thus ſolutions of gums, reſins,

reſins, or ſpermaceti, made by means of the yolk of an egg, in a proper vehicle, are called emulſions.

EMUNCTORY, in anatomy, a general term for all thoſe parts which ſerve to carry off the excrementitious parts of the blood and other humours of the body. Such more eſpecially are the kidneys, bladder, and moſt of the glands.

ENÆMON, *εναιμων*, in medicine, an epithet often applied by Hippocrates and Galen, to ſuch topical medicines as are appropriated to a wound newly inflicted, before the blood be ſtopped.

ENÆOREMA, in medicine, that pendulous ſubſtance which floats in the urine. It is alſo called ſublimamentum, and nubeculæ, from its reſemblance to little clouds.

ENALLAGE, in grammar, is when a poſſeſſive pronoun is put for a relative, or one mood or tenſe of a verb is put for another, &c.

ENALLAGE, in rhetoric, is a figure whereby the diſcourſe is changed and reverſed, contrary to all the rules of the language; but this not done altogether at pleaſure, or without reaſon.

ENALURON, according to Guillim, is a border charged all round with birds; though others will have it to ſignify, in orle, or form of a border.

ENAMEL, vulgarly called AMEL, is a kind of coloured glaſs, uſed in painting in enamel.

ENAMEL *Painting*, a ſpecies of painting differing from all other kinds of painting, in employing, as a vehicle for the colours to hold the parts together, and bind them to the ground they are laid upon, glaſs or ſome vitreous body; which being mixed with the colours, and fuſed or melted by means of heat, becomes fluid; and having incorporated with the colours in that ſtate, forms together with them a hard maſs when grown cold; and anſwers, therefore, the ſame end in this, as oil, gum-water, ſize, or varniſh, in the other kinds of painting.

The glaſs or vitreous body applied to this purpoſe of mixing with the colours, in order to bind them to the grounds, is called a flux; and makes one principal claſs of the ſubſtances uſed in enamel painting. When this flux is eaſily fuſible, that is, melts with a leſs degree of heat, it is, in the ſtyle of thoſe who work in enamel, ſaid to be ſoft, and when it is reluctant to melt, and requires a greater degree of heat, it is called hard; and theſe terms are as well applied to the matter of the enamel grounds, and all other vitreous ſubſtances concerned, as to the fluxes. It is, in general, a perfection of the flux to be ſoft, or run eaſily into fuſion: but the great point, with reſpect to this particular, is, that when ſeveral mixtures of colours and fluxes are uſed at the ſame time, they ſhould all correſpond to each other in the degree of this quality; otherwiſe ſome would be rendered too fluid, and perhaps run the matter of the enamel ground into fuſion, and mix with it, while others remained ſolid and inſufficiently fuſed themſelves. It is always neceſſary, likewiſe, that the enamel of the ground ſhould be conſiderably harder than the mixtures for the colours: for if they both melt with the ſame degree of heat, they will neceſſarily run together.

It is requiſite that the body painted in enamel ſhould undergo a heat ſufficient to melt ſoft glaſs, for the matter of ſuch body can only be gold, ſilver, copper, porcelain, or china-ware, hard glaſs, and earthen-ware: and where the metals are uſed, if the painting be of the nature of a picture, or demand a variety of colours, it is neceſſary that a ground of white, or ſome other colour, ſhould be laid on the metal; the body of which ground muſt neceſſarily be of the ſame vitreous nature as the flux, but harder; as nothing elſe can endure ſo great a heat that is capable of incorporating with, and binding the matter of the white, or other colour, to the ſurface of the metal. The grounds, therefore, make another principal claſs of the ſubſtances uſed in enamel painting.

The third claſs is the colours, which muſt likewiſe be bodies capable of ſuffering the heat of melted glaſs: and ſuch as will either themſelves be converted into glaſs, or kindly incorporate with it in a melted ſtate. This of courſe confines the matter of ſuch colours to metals, earths, or other mineral bodies; all vegetable and animal ſubſtances being calcined and analyzed with a greatly leſs degree of heat than the loweſt ſufficient to work enamel.

The fourth kind of ſubſtance is what is called the ſecondary vehicle; which is, ſome fluid body for laying on the ground, and working with the pencil, the flux and colours when mixed together: ſince, as they form only a dry powder, they could not be uſed as paint without ſome ſuch medium. But as this is to ſerve only for ſpreading and laying on the matter of the enamel, and not, like other vehicles, to aſſiſt in holding the colours together, and binding them to the ground, that being in this kind of painting the office of the flux; it is neceſſary, that it ſhould be ſome ſuch ſubſtance as will evaporate and dry away without leaving any part behind; which would otherwiſe be heterogeneous matter with regard to the enamel, and conſequently injurious to it. Eſſential oils have been, therefore, uſed for this purpoſe, as they have this quality of wholly drying away on the firſt approach of heat, together with a ſlight unctuoſity, which renders them capable of making the matter of the enamel work properly with the pencil.

The baſis of enamel is the fineſt cryſtal, made of the beſt kali from Alicant, and ſand vitrified together. To this fundamental compoſition are added crocus martis for yellow, and æs uſtum for green.

There are three kinds of enamel; the firſt for imitating precious ſtones; the ſecond is for painting in enamel; and the third is uſed by the enamellers, jewellers, and goldſmiths, on gold, ſilver, and other metals. The compoſition is the ſame in the main in all three kinds; the difference only conſiſts in giving it the proper colour and tranſparency.

The white enamel uſed by painters is the ſame with the common enamel, only it is ground and cleanſed with aqua-fortis; then waſhed in fair water, and pounded again in a flint or agate mortar.

The black is made of perigeux, well calcined and ground with oil of aſpic, with an equal quantity of the enamellers or goldſmiths black added thereto.

The ruddy brown is made with leys of vitriol and ſalt-petre, or with the ruſt of iron ground on an agate with oil of aſpic.

The yellow enamel for jewellers, goldſmiths, &c. is brought chiefly from Venice and Holland, in little thin cakes of different ſizes, with the maker's mark ſtruck on it with a puncheon.

Vermilion red is made of vitriol calcined in a moderate fire for half an hour, between two crucibles luted together; afterwards waſhed in aqua-fortis, and then in fair water.

Lake-red is compoſed of fine gold, diſſolved in aqua-regia, with ſal-ammoniac or common ſalt; then put into a cucurbit with ſpring water and mercury in a ſand heat for twenty-four hours: then the powder at the bottom is to be ground with double its weight of flour of ſulphur, and put into a crucible over a gentle fire: and, after the ſulphur is exhaled, the remaining red-powder is ground with rocaille.

Blue is made of the azure or lapis lazuli uſed by oil-painters, well purified with brandy, and ſet in a bottle for five or ſix days expoſed to the ſun.

An amber colour is made by white copperas calcined. From the combination of theſe ſeven or eight colours ariſes the variety of all the reſt.

Manner of laying on and burning the ENAMEL *Grounds.* — The matter of the enamel muſt be firſt finely levigated and ſearched: and the body to be enamelled ſhould be made perfectly clean. The enamel muſt be then laid on as even as poſſible by a bruſh or pencil, being firſt tempered with oil of ſpike; and the diſtance of time betwixt the laying on the ground and burning the piece ſhould not be too great; becauſe the oil will exhale and leave the matter of the enamel a dry incohering powder; which will be liable to be rubbed or ſhaken off by the leaſt violence. This is the common method; but there is a much better way of managing this part of the work by means of a ſearce, in which the enamel is ſpread with very little trouble, and the greateſt part of the oil of ſpike ſaved. The method of performing this is, to rub the ſurface to be enamelled over with oil of ſpike; and then, being laid on a ſheet of paper or piece of leather, to ſave

that part of the enamel which does not fall on a proper object, to ſearce the matter upon the oiled ſurface till it lie of a proper thickneſs; but great care muſt be taken, in this method of proceeding, not to ſhake or move too forcibly the pieces of work thus covered with the powdered enamel.

It is uſual to add oil of turpentine to the oils of ſpike or lavender, in order to make them go further, and ſave the expence attending the free uſe of them; and others add alſo a little olive or linſeed oil, or ſome, in the place of them, crude turpentine. The uſe of the ſpirit of turpentine is very allowable; for it is the ſame for this purpoſe as the oils of ſpike or lavender; except that it wants the glutinous quality which makes them ſerviceable in ſpreading the enamel: but with reſpect to the uſe of the oils of olive and linſeed, or any other ſubſtantial oil, it is very detrimental, tending to reduce the metalline calxes; and leaving a ſmall proportion of black coal or aſhes, which muſt neceſſarily injure the white colour of the ground.

When plates, as in the caſe of pictures, dial-plates, &c. are to be enamelled, they ſhould always be made convex on the outerſide, and concave within; and all pieces of enamel formed of metal, where the figures does not admit of their being thick and ſolid, ſhould be of the ſame kind of form: otherwiſe they will be very apt to warp in the heat; and cannot be brought ſtraight, after they are taken out of the fire, without cracking the enamel. For this reaſon, likewiſe, it is proper to enamel the work all over, as well on the wrong as right ſides, to prevent the heat from calcining the metal; which would both contribute to its warping, and weaken the texture of it.

The enamel being laid on the body to be enamelled, when the fixed muffle is uſed, the piece muſt be gently lifted on to the falſe bottom; and put in that ſtate into the muffle fixed in the furnace, by thruſting the falſe bottom into it as far as it will go: but it is beſt to defer this till the fire be perfectly in order, which muſt be known by putting a bit of tile or china with ſome enamel on it of the ſame tone with that uſed as a proof; and another proof of the ſame kind may be alſo put along with the work into the muffle; which, being taken out, may ſhew how the operation proceeds.

When coffins are uſed, the ſame general method is to be purſued: the pieces of work to be enamelled are to be laid on the bottom of the coffin till it be covered: and then the ſecond flooring or falſe bottom is to be fixed in its place, and covered in the ſame manner; after which the lid is to be put on; and well ſecured, in the joints it forms with the ſides of the coffin, by fire-lute. The proof, in this caſe, ſhould be laid on the lid, on the part next the ſide door of the furnace; and it may be expedient, eſpecially till the working of the furnace, and the kind of enamel uſed be very well underſtood, to have two or three of theſe proofs. The enamel work being thus put into the coffins, they ſhould be ſet on the dome of the furnace, that they may be moderately heated, before they be put into the furnace, which would otherwiſe endanger their cracking; and when they are ſo heated, proof having been made, by means of a ſmall bit of china, or copper covered with the enamel, that the fire be of a due force, they muſt be conveyed into the furnace thro' the ſide door, and muſt reſt on the pieces of fire-ſtone placed for that purpoſe on the flooring in the back part of the furnace. It is requiſite nevertheleſs, that the conveying them into the furnace ſhould be managed with particular care to prevent the ſhaking off the enamel; and it muſt be done by means of the peel or inſtrument adapted to this purpoſe; on which the coffin being laid, it muſt be gently thruſt into the furnace till the coffin be in its proper ſituation, with reſpect to diſtance from the ſides of the furnace; and then the further end of the peel muſt be turned ſlowly towards the front of the furnace; the coffin being at the ſame time ſhoved off from it by means of the flat end of the tongs, introduced through the door for feeding the fire, till it ſtand entirely on the fire-ſtones, when the peel muſt be withdrawn. The operation being finiſhed, the peel muſt be again introduced under the coffin, by raiſing firſt the neareſt end of it, by means of the tongs through the door in the front; and then the other parts gradually, till the peel ſupport it; and then they muſt be drawn out together, and may be beſt placed on the dome of the furnace, that by cooling more gradually the temper of the enamel may be improved.

If it be required to burn a ſingle piece or two in the furnace, it may be done by means of the common or looſe muffle: in which caſe the enamel work being laid on the bottom or flooring of the muffle, and the muffle put over it, the whole muſt be conveyed into the furnace, by means of the tongs with turned points, through either of the doors; and a proof may be at the ſame time put in, on a piece of tile or ſpare bottom of a muffle: and the proceedings in other reſpects may be the ſame as with the fixed muffle, or the coffins.

Where there is no furnace, and it is deſired to burn enamel work on an open hearth, preparations muſt be made accordingly, and the flooring of the muffle being laid at a proper diſtance from the nozzle of the bellows, the work muſt be laid on it, and covered with the muffle; which being done, pieces of charcoal muſt be heaped over them, and the fire being lighted, muſt be blown up with the bellows, till it be ſufficient to flux the enamel; which muſt be examined by the proof put into the fire along with the work. The coals muſt then be taken off from the muffle, and the muffle, with the flooring and enamelled work, removed out of the fire, but kept near it to prevent their cooling too faſt; and if there be more work to be burnt, another muffle, &c. may be immediately put in the place of the other, and the ſame operation repeated; for it is a matter of indifference, whether the coals be burning when the work is put on the hearth, or kindled afterwards.

Pit coal may be uſed in the furnace, where enamel is burnt with the fixed muffle, or in coffins; which is indeed one principal conveniency attending the uſe of them, as it ſaves a conſiderable expence of charcoal; but where the open muffle is uſed, charcoal alone ſhould be employed; as the fumes of mineral coal are very detrimental to ſome colours, and deſtructive of the grounds, if whitened by arſenic, as the common white glaſs.

Manner of laying on and burning the ENAMEL *Colours.*—The colours being prepared, and reduced to powder by due levigation, and waſhing over where they are required to be extremely fine, and there is no unvitrified ſalt in the mixture, they muſt be tempered on a china or Dutch tile with oil of ſpike or lavender, to which moſt artiſts add likewiſe oil of turpentine; and ſome, a little linſeed or olive oil; and then uſed as paint of any other kind: but it ſhould be avoided to mix more of the colours with the eſſential oils than will be immdiately uſed; becauſe they dry away extremely faſt, and would not only be waſted, but give a coheſion to the particles of the colours, that would make them work leſs freely when again diluted with the oil.

The colours being thus laid on the pieces to be painted, the proceeding muſt be in all reſpects the ſame as with the grounds, in whatever manner they are to be burnt, either in the muffles or coffins; but greater nicety muſt be obſerved with reſpect to the fire, as the effects of any error in that point are of much greater conſequence in the burning the colours than grounds; eſpecially if the white of the grounds be formed from the calx of tin or antimony, and not arſenic.

Pit coal, as was above obſerved, may be employed for burning as well the colours as the grounds, where the muffle or coffins are uſed, or any other method purſued that wholly hinders the ſmoke and fumes from having any acceſs to the enamel.

ENARTHROSIS, in anatomy, a ſpecies of diarthroſis. See the article DIARTHROSIS.

ENCÆNIA, the name of three ſeveral feaſts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabeus, Solomon, and Zorobabel.

This term is likewiſe uſed in church hiſtory for the dedication of Chriſtian churches.

ENCAMPMENT, the pitching of a camp. See the article CAMP.

ENCANTHIS, in ſurgery, a tubercle ariſing either from the caruncula lachrymalis, or from the adjacent red ſkin; ſometimes ſo large, as to obſtruct not only the

puncta lachrymalia, but alſo part of the ſight, or pupil itſelf.

It is of two kinds, viz. mild, without hardneſs or pain; or malignant, which is livid and very painful. The mild kind is to be treated firſt by ſcarifying, and afterwards applying eſcharotic or cauſtic medicines; and if this proves inſufficient, the tumour may be touched, but with great caution, with lapis infernalis; and to divert the humours from the eye, iſſues and ſetons, with phlebotomy and cooling purges, are proper. If all theſe fail, the ſurgeon is to extirpate the tumour; in which caſe it is better to leave part of the morbid tubercle, than cut off any part of the lachrymal caruncle, as the remains of it may be afterwards cleared away by eſcharotics. After the operation, it is proper to apply deterging and healing medicines, or a collyrium of lapis tutiæ, myrrh, &c. till the wound is healed.

As to the malignant encanthis, inclining to be cancerous, it is generally better to let it alone, and to mitigate its uneaſineſs with cooling and lenient collyria, rather than exaſperate it by the operation, or by eſcharotic medicines.

ENCAUSTICE and ENCAUSTUM, the ſame with enamelling and enamel. See ENAMELLING and ENAMEL.

ENCEINTE, in fortification, is the wall or rampart which ſurrounds a place, ſometimes compoſed of baſtions or curtains, either faced or lined with brick or ſtone, or only made of earth. The enceinte is ſometimes only flanked by round or ſquare towers, which is called a Roman wall.

ENCEPHALI, in medicine, worms generated in the head, where they cauſe ſo great a pain, as ſometimes to occaſion diſtraction.

The encephali are very rare, but there are ſome diſeaſes wherein they ſwarm; from whence we are told peſtilential fevers have wholly ariſen. Upon the diſſection of one who died of this fever, a little, ſhort, red worm was found in the head, which Malmſey wine, wherein horſe radiſh had been boiled, could only deſtroy. This medicine was afterwards tried on the ſick, moſt of whom it cured.

The like worms have alſo been taken out by trepanning, and the patient cured. Thoſe worms that generate in the noſe, ears, and teeth, are alſo called encephali.

ENCEPPE, in heraldry, denotes fettered, chained, or girt about the middle, as is uſual with monkeys.

ENCHANTER, a perſon ſuppoſed to practiſe enchantment, or faſcination.

ENCHASING, INCHASING, or CHASING, the art of enriching and beautifying gold, ſilver, and other metal-work, by ſome deſign, or figures repreſented thereon, in low relievo.

Enchaſing is practiſed only on hollow thin works, as watch-caſes, cane-heads, tweezer-caſes, or the like. It is performed by punching or driving out the metal, to form the figure, from within ſide, ſo as to ſtand out prominent from the plane or ſurface of the metal. In order to this, they provide a number of fine ſteel-blocks, or puncheons, of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tops of theſe blocks, directly under the lines or parts of the figures; then, with a fine hammer, ſtriking on the metal, ſuſtained by the block, the metal yields, and the block makes an indenture, or cavity, on the inſide, correſponding to which there is a prominence on the outſide, which is to ſtand for that part of the figure.

Thus the workman proceeds to chaſe and finiſh all the parts by ſucceſſive application of the block and hammer, to the ſeveral parts of the deſign: and it is ſurpriſing to conſider with what beauty and juſtneſs, by this ſimple piece of mechaniſm, the artiſts in this kind will repreſent foliages, groteſques, animals, hiſtories, &c.

ENCHYSMA, in medicine, the ſame with clyſter. See the article CLYSTER.

ENCLITICA, in grammar, particles which are ſo cloſely united with other words, as to ſeem part of them, as in *virumque*, &c.

There are three enclitic particles in Latin, viz. *que*, *ne*, *ve*; but there are a great many in the Greek, as τε, τις, μω, μοι, σφ, σοι, &c.

ENCRATITES, *Encratitæ*, in church hiſtory, heretics who appeared towards the end of the ſecond century: they were called Encratites, or Continentes, becauſe they gloried in abſtaining from marriage, and the uſe of wine and animal food. Their chaſtity, however, was a little ſuſpected, on account of their uſing all ſorts of means to draw women into their ſect, and always keeping company with them.

ENCROACHMENT, or INCROACHMENT, in law. See INCROACHMENT.

ENCYCLOPÆDIA, the circle of arts and ſciences.

The word is formed from the Greek εν, in, κυκλος, a circle, and παιδεια, art, ſcience, or learning.

ENDECAGON, in geometry, the ſame with hendecagon. See HENDECAGON.

ENDEMIC, or ENDEMICAL DISEASES, thoſe to which the inhabitants of particular countries are ſubject more than others, on account of the air, water, ſituation, and manner of living.

The word is derived from the Greek εν, in, and δημος, people.

ENDIVE, *Endivia*, in botany, &c. the broad-leaved ſuccory. See the article CICHORIUM.

Marſigli deſcribes a plant, which he calls ſea-endive, from its reſemblance to the common garden endive.

ENDORSE, in heraldry, an ordinary, containing the eighth part of a pale, which Leigh ſays is only uſed when a pale is between two of them.

ENDORSED, *Endorſé*, in heraldry, is ſaid of things borne back to back, more uſually called adoſſé.

ENDOWMENT, in law, denotes the ſettling a dower on a woman; tho' ſometimes it is uſed figuratively, for ſettling a proviſion upon a parſon on the building of a church; or the ſevering a ſufficient portion of tithes for a vicar, when the benefice is appropriated.

ENEMA, in medicine, the ſame with clyſter. See the article CLYSTER.

ENEMY, in law, an alien or foreigner, who publicly invades the kingdom.

ENERGUMENS, in church hiſtory, perſons ſuppoſed to be poſſeſſed by the devil, concerning whom there were many regulations among the primitive Chriſtians.

They were denied baptiſm, and the euchariſt; at leaſt this was the practice of ſome churches: and though they were under the care of exorciſts, yet it was thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be preſent. See the article EXORCISM.

ENERGY, ενεργεια, a term of Greek origin, ſignifying the power, virtue, or efficacy of a thing. It is alſo uſed, figuratively, to denote emphaſis of ſpeech. See EMPHASIS.

ENFILADE, in the art of war, is uſed in ſpeaking of trenches, or other places, which may be ſcoured by the enemy's ſhot, along their whole length. In conducting the approaches at a ſiege, care muſt be taken that the trenches be not enfiladed from any work of the place. See the article TRENCHES.

ENFRANCHISEMENT, in law, the incorporating a perſon into any ſociety or body politic: thus, where any perſon is enfranchiſed, or made free, of any city, borough, or company, he is ſaid to have a freehold therein during life; and cannot, for barely endeavouring any thing againſt the corporation, forfeit the ſame.

Naturalization is alſo another kind of enfranchiſement. See NATURALIZATION.

ENGASTRIMYTHI, in pagan theology, the pythians or prieſteſſes of Apollo, who delivered oracles from within, without any action of the mouth or lips.

ENGINE, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pullies, ſcrews, &c. in order to raiſe, project, or ſuſtain any weight, or produce any effect which could not be eaſily effected otherwiſe.

Engines are extremely numerous; ſome uſed in war, as the battering-ram, balliſta, waggons, chariots, &c. others in trade and manufactures, as cranes, mills, preſſes, &c. others to meaſure time, as clocks, watches, &c. and others for the illuſtration of ſome branch of ſcience, as the

PLATE LXII.

Fig. 4. Ermine.

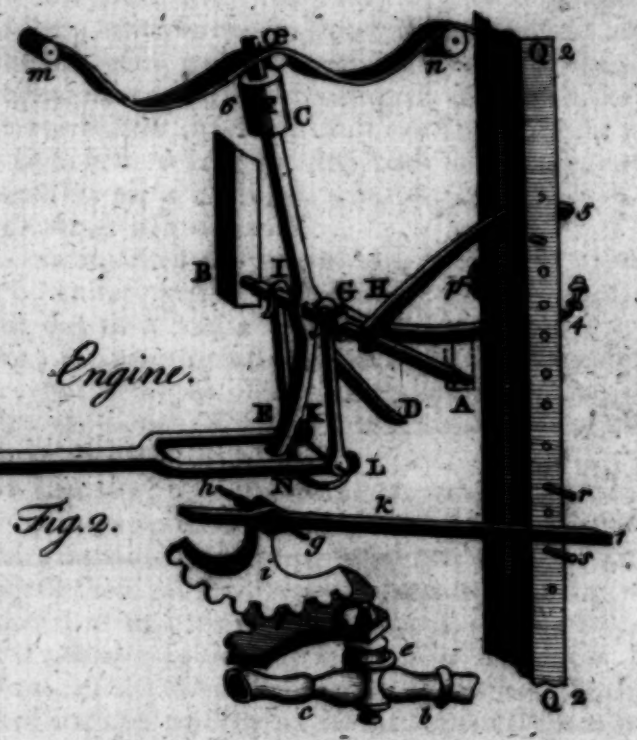

Fig. 2.

5 JA 59

the orrery, cometarium, and the like. See BATTERING-RAM, BALLISTA, &c.

In general we may obſerve, concerning engines, that they conſiſt of one, two, or more of the ſimple powers variouſly combined together; that in moſt of them the axis in peritrochio, the lever, and the ſcrew, are the conſtituent parts; that in all a certain power is applied to produce an effect of much greater moment; and that the greateſt effect, or perfection, is when it is ſet to work with four ninths of that charge which is equivalent to the power, or will but juſt keep the machine in equilibrio. See the articles MAXIMUM and MECHANICS.

In all machines, the power will juſt ſuſtain the weight, when they are in the inverſe ratio of their diſtances from the center of motion. See the articles POWER and EQUILIBRIUM.

It being of the utmoſt importance to diminiſh the friction of engines, ſeveral contrivances have been invented for this purpoſe. See the article FRICTION.

ENGINE for extinguiſhing fires, a machine for raiſing a conſiderable quantity of water, in one continued ſtream, for the extinguiſhing accidental fires. See a perſpective view of the whole engine, ready for working, in plate LXI. *fig.* 4.

The nature and effect of this engine will be eaſily underſtood from a perpendicular ſection of it repreſented in plate LXI. *fig.* 5. The water is raiſed by the preſſure of the atmoſphere, by the force of the piſtons, and by the ſpring of condenſed air, in the following manner: thus, when the piſton R is raiſed, a vacuum would be made in the barrel T V, did not the water follow it from the inferior canal E M, though the valve H, which riſes through the tube E F, immerſed in the water of a veſſel, by the preſſure of the atmoſphere on the ſurface thereof. By the depreſſion of the piſton R, the water in the barrel T V is forced through the ſuperior canal O N, to enter by the valve I, into the air veſſel *a b c d*; and the like being done alternately by the other barrel W X, and its piſton S, the air-veſſel is by this means continually filling with water, which greatly compreſſes the air above the ſurface of the water in the veſſel, and thereby proportionably augments its ſpring, which is at length ſo far increaſed, as to re-act with great force on the ſurface Y Z of the ſubjacent water; which aſcending through the ſmall tube *e f*, to the ſtop-cock *p*, is there, upon turning the cock, ſuffered to paſs through a pipe *h*, fixed to a ball and ſocket, from the orifice of which it iſſues with a great velocity, to a very great height or diſtance, in a continued ſtream, directed every way, or to any particular place, by means of the ball and ſocket.

The greateſt artifice of this engine is its contrivance to produce a continued ſtream, which is done by compreſſion, and the conſequent increaſed elaſticity of the air in the barrel *a b c d*, called the air-veſſel: for the air, being an elaſtic fluid, will be capable of compreſſion in any degree by the water forced in through the valves at I K; and, ſince the force of the air's ſpring will always be inverſely as the ſpace which it poſſeſſes, it follows, that, when the air veſſel is half full of water, the air will be compreſſed into half the ſpace it poſſeſſed at firſt, and therefore its ſpring will be twice as great as at firſt.

But this ſpring at firſt was equal to the preſſure of the atmoſphere; for if it was not, it could not have ſuſtained or reſiſted the preſſure of the atmoſphere which ſtood over it, and conſequently could not have filled the veſſel before the water was driven in; which yet we find it did, and maintained an æquilibrium with the common air.

The veſſel then being half filled with water, or the air compreſſed into half its firſt ſpace, its ſpring will be in this caſe equal to twice the preſſure of the atmoſphere; and therefore, when the ſtop-cock at *p* is turned, the air within the ſubjacent water, with twice the force it meets with from the external air in the pipe *e f*, will cauſe the water to ſpout out of the engine to the height of thirty-two or thirty-three feet, if the friction be not too great.

When the air veſſel is $\frac{2}{3}$ full of water, the ſpace which the air takes up is only $\frac{1}{3}$ of its firſt ſpace; whence its ſpring being three times as great as that of the common air, it will project the water with twice the force of the atmoſphere, or throw it to the height of 64 or 66 feet.

In the ſame manner, when the air veſſel is $\frac{1}{4}$ full of water, the air will project it to the height of 96 or 99 feet; and when $\frac{3}{4}$ full of water, to the height of 132 feet.

As the air veſſel is the cauſe of the continual ſtream, we may naturally infer that, if ſuch an air veſſel were adapted to the common houſe-pump, it would then become a fire engine, or very uſeful for extinguiſhing fires that may happen in or near the houſe. Now this may be effected in a manner, either the ſame with, or analogous to, that which follows: A B C D (*fig.* 6.) is the barrel of the pump, P H the rod and piſton; C W the pipe going down to the water of the well at W; towards the lower part of the barrel is a ſhort tube, by which the air veſſel F E is fixed to, and communicated with, the barrel of the pump. A M N L is a collar of leather ſo fixed on the top of the barrel, and adapted to the rod, that it may move freely in the leather, without permitting the air to paſs in or out between. The nozzle or ſpout D has a ſtop-cock S to ſhut off the water, or let it paſs out as required. Q is a piece ſcrewed on to direct the ſtream by a ſmall pliant leathern pipe at the end.

Now it is plain, when the piſton is raiſed from the bottom of the pump barrel, the water above it will be forced into the air veſſel, and there compreſs the air, the ſtop-cock being ſhut; it will alſo compreſs the air on the top of the barrel, for the water will not be higher than the ſpout D at firſt, when the ſtop-cock is ſhut: but afterwards, as the air is confined, it will be compreſſed at top, and the water will riſe to I.

This compreſſed air, in each place, will act upon the water by its ſpring, and upon turning the ſtop-cock, will force it out in a continual ſtream, through a pipe at Q; and with a greater or leſſer degree of force, as occaſion requires, that being abſolutely in the power of the perſon working the pump This invention we owe to the learned Sir James Creed.

Fire ENGINE, or *Steam* ENGINE, a machine for raiſing water by the help of fire. The fire-engine is the moſt admirable, curious, and compounded machine that we find among all thoſe whoſe inventions have been owing to the diſcoveries of modern philoſophy, and which affords the greateſt advantages to mankind. The fire engine is of two ſorts, of which we ſhall here give the theory and figures of each, according to the lateſt perfection in which they are made.

The marquis of Worceſter, in his century of inventions, publiſhed in the year 1663, is probably the firſt who propoſed raiſing great quantities of water by the force of fire turning water into a ſteam; and he mentions ſome engine of this kind, which he ſays played a continual ſtream, in the manner of a fountain, forty feet high. He alſo ſays, that a perſon attending it turned two cocks; that one veſſel of water being conſumed, another begins to force and re-fill with cold water; and this alternately and ſucceſſively, the fire being attended and kept conſtantly burning by the ſame perſon, in the interim between turning the cocks.

Captain Savery, having read this account, immediately attempted to raiſe water by fire, and was the firſt who erected an engine for this purpoſe, in the form we have ſince had them. To ſecure the invention to himſelf, he purchaſed all the books that were to be found, printed by the marquis upon that occaſion, and burnt them; and at the ſame time declared that he found out the method by accident. He made many experiments to bring the machine to perfection, and erected ſeveral for gentlemen's ſeats.

But the progreſs of the engine was ſtopped, till long time afterwards, when Mr. Newcomen and Mr. J. Cawley contrived another way to raiſe water by fire, where the ſteam to raiſe the water from the greateſt depths of mines is not required greater than the preſſure of the atmoſphere; and this is the preſent ſtructure of the engine, which is now of about fifty-five years ſtanding.

We ſhall ſhew, under the article PUMP, that water may be drawn from any depth by a compound pump. Suppoſe the depth = 150 feet, and the diameter of the pump at plate LXII. *fig.* 1. be 7 $\frac{1}{4}$ inches, then the weight of a cylindric column of water 150 feet high, and 7 $\frac{1}{4}$ inches diameter, will be about 3000 lb weight. If now the rod of this pump were hung by a chain to the end

of the lever *h h*, as at H, and at the other end another power were applied, as at L, with a ſuperior force, the pump might be worked, and the water raiſed by that power.

Now this power cannot be human, or the ſtrength of man; for it will require a hundred men to pull down the beam, each pulling with the force of thirty pound; and an hundred men to relieve them, when weary; for the pump in a mine muſt not ſtand ſtill: but two hundred men would be too expenſive. If we allow horſes, and one horſe equal to five men, there muſt be twenty horſes working at a time, and twenty more to relieve theſe; which great number of horſes, though leſs expenſive than the men, will be found too great for moſt mines: and neither men nor horſes would be able to give more than fifteen or ſixteen ſtrokes in a minute.

Some other power therefore muſt be applied, and this may be effected as follows: B is a large boiler, whoſe water, by the fire under it, is converted into an elaſtic ſteam. The great cylinder C C is fixed upon it, and communicates with it by the pipe D *d*; on the lower orifice of which, within the boiler, moves a broad plate, by means of the ſteam-cock, or regulator E 10, ſtopping or opening the paſſage to prevent or permit the ſteam to paſs into the cylinder, as occaſion requires. The diameter of the pipe D is about four inches.

The ſteam in the boiler ought always to be a little ſtronger than the air, that when let into the barrel, it may be a little more than a ballance to the external air, which keeps down the piſton at the bottom *d n*. The piſton being by this means at liberty, the pump-rod will, by its great weight, deſcend at the oppoſite end to fetch a ſtroke; for the weight of ſeventy or eighty yards of iron rod amounts to nine or ten hundred weight; whereas the piſton, and other weights at the other end, is not above four or four and a half hundred weight. The end of the lever at the pump, therefore, will always preponderate the other, and deſcend when the piſton is at liberty.

The handle of the ſteam cock E 10, being turned towards *n*, opens a pipe D to let in the ſteam; and being turned towards O, it ſhuts it off, that no more can enter. The piſton is now raiſed towards the top of the barrel at C, and the barrel is full of ſteam. The lever O 1 muſt then be lifted up, to turn, by its teeth, the injecting cock at N, which permits the water brought from the ciſtern *g*, by the pipe *g* M N, to enter the bottom of the barrel at *n*, where it flies up in the form of a fountain, and ſtriking againſt the bottom of a piſton, the drops, being driven all over the cylinder, will, by their coldneſs, condenſe the ſteam into water again, and precipitate it to the bottom of the barrel.

Mr. Henry Beighton made an experiment to determine the rarity of the ſteam, and found the content of the barrel of ſteam was 113 gallons; and ſince there were ſixteen ſtrokes in a minute, therefore $113 \times 16 = 1808$ gallons of ſteam per minute. He alſo obſerved, that the boiler required to be ſupplied with water at the rate of five pints per minute: and ſince 282 cubic inches make a gallon, $35\frac{1}{4}$ make a pint, and $5 \times 35\frac{1}{4} = 176\frac{1}{4}$ in five pints; alſo the cubic inches of ſteam are $1808 \times 282 = 509856$; if then we ſay, as $176\frac{1}{4} : 509856 :: 1 : 2893$; or one cubic inch of water is expanded into 2893 inches of ſteam; conſequently the ſteam in the barrel is reduced to $\frac{1}{2893}$ part, when turned to water by the jet of cold water; and therefore a ſufficient vacuum is made in the barrel, for the piſton to deſcend unballanced, by the preſſure of the air.

The piſton being forced down, raiſes the other end of the lever, and conſequently the piſton of the pump which brings up and diſcharges the water at *p*. Now this whole operation of opening and ſhutting the ſteam regulator and injection cock will take up but little more than three ſeconds; and will therefore produce very well ſixteen ſtrokes in a minute.

That the ciſtern *g* may always be ſupplied with water, there is an arch *x* fixed near the arch H at the pump-end, from whence another pump-rod *k*, with its piſton, draw water from a ſmall ciſtern near the mouth of a pit, ſupplied from the water raiſed at *p*, and forces it up the pipe *m m m* into the ciſtern *g*, which, therefore, can never want water.

That the leathers of the piſton C may be always ſupple and ſwelled out ſo as to be always air-lights, a ſmall ſtream of water is ſupplied from the injecting pipe M by the arm *z*. On the top of the cylinder is a larger part or cup L, to hold the water that lies on the piſton, leſt it ſhould overflow when the piſton is got to its greateſt height, as at W; at which time, if the cup be too full, the water will run down the pipe V to the waſte well at Y.

The water in the boiler which waſtes in generating ſteam, is ſupplied by a pipe I *i* about three feet long, going into the boiler a foot below the ſurface of the water. On the top of this pipe is a cup or funnel I ſupplied by the pipe W with water from the top of the ciſtern, which has the advantage of being always warm, and not ſo apt to check the boiling of the water in the copper.

That the boiler may not have the ſurface of the water too low, which would endanger burſting, or too high, which would not have room enough for ſteam, there are two gage-pipes at G; one going a little below the ſurface of the water when at a proper height, and the other ſtanding a little above it. When every thing is right, the ſtop-cock of the ſhorter pipe, being open, gives only a ſteam, and that of the long one water; but, if otherwiſe, both cocks will give ſteam when the ſurface is too low, and both give water when it is too high; and hence the cock which feeds the boiler at I may be opened to ſuch a degree, as always to keep the ſurface of water to its due height.

The cold water, conſtantly injected into the cylinder to condenſe the ſteam, is carried off by the eduction-pipe *d* T Y, going from the bottom of the cylinder to the waſte well Y, where going a little under water, it has its end turned up, with a valve Y, to keep the air from preſſing out into the pipe, but permitting the injected water coming the other way to be diſcharged, whereby the cylinder is kept empty.

Leſt the ſteam ſhould grow too ſtrong for the boiler, and burſt it, there is a valve fixed at *b*, with a perpendicular wire ſtanding up from the middle of it, to put weights of lead upon, by which to examine the ſtrength of the ſteam puſhing againſt it from within. Thus the ſteam is known to be as ſtrong as the air, if it will raiſe up ſo much weight on the valve, as is at the rate of fifteen pounds to an inch ſquare; becauſe that is the weight of air, nearly, on every ſquare inch. When the ſteam becomes ſtronger than is required, it will liſt up the valve, and go out. This valve is called the puppet-clack.

The ſteam has always a variable ſtrength, yet never $\frac{1}{15}$ ſtronger or weaker than common air: for it has been found that the engine will work well when there is the weight of one pound on each ſquare inch of the valve *b*. This ſhews that the ſteam is then $\frac{1}{15}$ part ſtronger than the common air. Now as the height of the feeding pipe from the funnel F to the ſurface of the water S *s* is not above three feet, and three feet and a half of water is $\frac{1}{15}$ of the preſſure of the air; if the ſteam were $\frac{1}{15}$ part ſtronger than air, it would puſh the water out at E; which, ſince it does not, it cannot be ſtronger than air, even in this caſe, where, the regulator being ſhut, it is moſt of all confined.

When the regulator is opened, the ſteam gives the piſton a puſh, which riſes it up a little way; then filling a greater ſpace, it comes to be of the ſame ſtrength, and ſo a balance to the atmoſphere; thus the piſton, being at liberty, riſes to the top W. The ſteam, now expanded into the whole capacity of the cylinder, is weaker than the air, and would not ſupport the piſton, were it not for the greater weight at the other end of the lever, which keeps it up. The ſteam each ſtroke drives the injected water of the preceding ſtroke out of the eduction pipe *d* T Y, and would itſelf follow, and blow out at the valve Y, which is not loaded, if it were ſtronger than the air, which it never does. If it were exactly equal to the ſtrength of the air, it would juſt drive all the water out at Y, but could not follow itſelf, the preſſure being on each ſide the valve equal by ſuppoſition. If it be weaker than the air, it will not force all the water out of the pipe *d* T Y, but the ſurface will ſtand, ſuppoſe, at T,

Vaulolie's Engine. Fig. 4.

where the column of water TY, added to the ſtrength of the ſteam, is equal to the preſſure of the air. When the ſteam is $\frac{1}{10}$ weaker than the air, the height TY = three feet and a half. Now, ſince the whole perpendicular diſtance from *d* to Y is but four feet, and the ſteam always ſufficient to expel the water; it is plain it can never be more than $\frac{1}{13}$ part weaker than the air, when weakeſt.

There is air in all the water injected; and though that air cannot be taken out or condenſed with the ſteam, yet will it precipitate and fall through the ſteam to the bottom of the cylinder, as being much heavier. For ſteam is to water, as 1 to 2893, in its denſity; but the denſity of air is to that of water, as 1 to 864, nearly; therefore, the rarity of ſteam is to that of air, as 2893 to 864; the air will, therefore, fall through the ſteam to the bottom, and from thence be driven out through a ſmall pipe opening into the cup at 4, on which is a valve. Now, when the ſteam firſt ruſhes into the cylinder, and is a little ſtronger than the outward air, it will force the precipitated air to open the valve at 4, and make its eſcape; but the ſteam cannot follow, becauſe it is weaker than the outward air, as the piſton gives it room by aſcending to expand. This valve, from the noiſe it makes, is called the ſnifting-clack.

Among the greateſt improvements of this engine, we may reckon that contrivance by which the engine itſelf is made to open and ſhut the regulator and injunction-cock, and that more nicely than any perſon attending could poſſibly do it. For this purpoſe, there is fixed to an arch 12, at a proper diſtance from the arch P, a chain, from which hangs a perpendicular piece or working beam QQ, which comes down quite to the floor, and goes through it in a hole, which it very exactly fits. This piece has a long ſlit in it, and ſeveral pin-holes and pins, for the movement of ſmall levers deſtined to the ſame office of opening and ſhutting the cocks, after the following manner.

Between two perpendicular pieces of wood on each ſide, there is a ſquare iron axis AB (plate LXII. *fig.* 2.) which has upon it ſeveral iron pieces of the lever kind. The firſt is the piece CED, called the Y, from its repreſenting that letter inverted by its two ſhanks E and D; on the upper part is a weight F to be raiſed higher or lower, and fixed, as occaſion requires. This Y is fixed very faſt upon the ſaid iron axle AB.

From the axle hangs a ſort of an iron ſtirrup IKLG, by its two hooks IG, and having on the lower-part two holes K, L, through which paſſes a long iron pin LK, and keyed in the ſame. When this pin is put in, it is alſo paſſed through the two holes in the ends E, N, of the horizontal fork or ſpanner EQN, joined at its end Q, to the handle of the regulator V 10. From Q to O are ſeveral holes, by which the ſaid handle may be fixed to that part of the end which is moſt convenient.

Upon this axis AB is fixed at right angles to the Y, an handle or lever G 4, which goes on the outſide of the piece Q 2, Q 2, and lies between the pins. Another handle is alſo faſtened upon the ſame axle, viz. H 5, and placed at half a right-angle to the former G 4; this paſſes through the ſlit of the piece Q 2, Q 2, lying on one of the pins. Hence we ſee, that when the working beam goes up its pin in the ſlit, it lifts up the ſpanner H 5, which turns about the axle ſo faſt, as to throw the Y, with its weight F, from C to 6, in which direction it would continue to move, after it had paſſed the perpendicular, were it not prevented by a ſtrap of leather fixed to it at *o*, and made faſt at the ends *m* and *n*, in ſuch a manner as to allow the Y to vibrate backwards and forwards about a quarter of a circle, at equal diſtances on this ſide, and that of the perpendicular.

As things are repreſented in the figure, the regulator is open, its plate TY being ſhewn on one ſide the pipe S, which joins the cylinder and boiler. The piſton is now up, and alſo the working beam near its greateſt height; the pin in the ſlit has ſo far raiſed the ſpanner H 5, that the weight F on the head of the Y is brought ſo far from *o*, as to be paſt the perpendicular, and ready to fall over towards *m*, which, when it does, it will by its ſhank E, with a ſmart blow, ſtrike the iron pin KL, and drawing the fork horizontally towards the beam Q, will draw the end 10 of the regulator towards 6, and thereby ſhut it, by ſlipping the plate Y under the holes of the throat-pipe S.

Immediately after the regulator is ſhut, the beam riſing a little higher, with its pin S on the outſide upon the lower part, lifts up the end *k* 1 of the handle of the injection-cock, and opens it by the turning of the two parts with teeth. The jet immediately making a vacuum, the beam again deſcends, and the pin *r*, depreſſing the handle *k* 1, ſhuts the injection-cock; and the beam continuing to deſcend, the pin *p* bears down the handle G 4, and throwing back the Y, its ſhank D throws forward the fork NQ, and again opens the regulator to admit freſh ſteam. After this every thing returns as before; and thus is the engine moſt wonderfully contrived to work itſelf. After the engine had been made, as above deſcribed, for many years, it received another improvement of very great advantage; and that was, inſtead of feeding the boiler with warm water from the top of the cylinder, by the pipe W (*fig.* 1.) above, and F *f* below, they contrived to ſupply it with the ſcalding hot water which comes out of the eduction-pipe *d* T Y, which now, inſtead of going to the waſte-well at Y, was turned into the boiler on the top part; and as the eduction-pipe before went out at the ſide of the cylinder, it was now inſerted in the bottom of the ſame; and though the preſſure of ſteam in the boiler be ſomewhat ſtronger in the cylinder, yet the weight of water in the eduction-pipe, being added to the force of ſteam in the cylinder, will carry the water down continually, by overcoming the reſiſtance in the boiler.

This is the lever-engine with the improvements of Mr. Newcomen and others; but as captain Savary's, or rather the marquis of Worceſter's, is very cheap in reſpect of this machine, and as it is alſo applicable with great advantage when the height to which the water is to be raiſed does not exceed 100 or 150 feet, we ſhall here ſubjoin a view of that engine, with the improvements of Dr. Deſaguliers.

The boiler BB (plate LXIII. *fig.* 1.) is a large copper body of a globular form, which will beſt of all withſtand the very great force of ſteam, that is in this caſe neceſſary. Round the body of this boiler the fire and flame are conducted, as ſhewn at TTT. It has a copper cover ſcrewed on, which contains the ſteam-pipe CD, and two gage-pipes N, O, which, by turning their cocks, ſhew the height of the ſurface of the water within, as in the other engine.

On the ſame cover at P is a valve, over which lies a ſteelyard, with its weight Q to keep it down, the ſtrength of the vapour being this way moſt exactly eſtimated: for being in the nature of a lever of the third ſort, it is plain, if the beam of the lever be divided into ten equal parts, and the firſt of them be upon the middle of the valve, and the weight Q hangs at the ſecond, third, fourth, &c. diviſion, that then the force of the ſteam which can raiſe up the valve will be two, three, four, &c. times as great as the weight. If the area of the valve be a ſquare inch, and Q = 15 pounds, hanging at the ſecond diviſion, is raiſed by a ſteam puſhing up the valve, it will ſhew the ſteam will then preſs with the force of two atmoſpheres; but great care muſt then be taken about it, leſt the ſteam, ſo very ſtrong, burſt the boiler to pieces.

The ſteam is carried from the boiler to the copper-veſſel A, by means of the pipe CD; and is let into the ſame by turning the handle K of the ſteam-cock DI. The key of this cock is kept down by the ſcrew L, and held up by the gibbet DL. The handle turned from K to *k*, admits a paſſage to the ſteam into the copper receiver A.

This receiver A communicates at bottom with the ſuction-pipe ZH going down to the water H in the well X; and above, with the forcing-pipe EE, which goes up a little above the water of the reſervoir R; between theſe two pipes are two valves F and G, both opening upwards. The ſteam being let in upon the water of the receiver A, forces it up the valve F, and the pipe EE, to the reſervoir, and then the ſaid receiver is full of hot ſteam.

This ſteam, in the receiver, is condenſed by a jet of cold water coming from the forcing-pipe by the ſmall pipe MI, being let in and ſhut off by the cock at M.

The ſteam being condenſed by this jet, will be reduced within a very ſmall ſpace, and ſo make a vacuum; upon which the water in the well will ruſh up the forcing-pipe to reſtore the æquilibrium, and thus again fill the receiver A; the little air being compreſſed within a ſmall compaſs at the top above *a b*.

That there may be always water in the force-pipe for the jet, there is a little pipe which brings the water to it from the reſervoir, with the ſmall ſtop-cock Y to ſhut it off upon occaſion. The valves at F and G are examined at any time, by unſcrewing the pin 1 to looſen the ſtrap 2, and let down the flanch 3; all which parts are ſhewn larger in *fig.* 2.

By the particular contrivance of the cock at D I, and its key, the water is made to paſs from the force-pipe to the boiler, to ſupply the waſte in ſteam. This is plainly ſhewn in the ſection of the cock and key, where 5 is the top of the key; 6 is a hole on one ſide, which goes down to the bottom to convey the ſteam or jet of water alternately to the receiver; 7 is a notch on the other ſide, to take in the water from the force-pipe, and conduct it to the boiler B. How this is done is eaſy to conceive from a view of the two ſections of the cock and key in two poſitions within it.

The boiler may hold five or ſix hogſheads, and the receiver one hogſhead per hour. This ſteam makes a vacuum ſo effectually, as to raiſe water from the well to the height of 29 or 30 feet; and ſuppoſe the ſteam able to lift up the ſteelyard, with its weight hanging at the ſixth diviſion, it will then be able to raiſe a column of water about 50 yards high, as being then ſix times ſtronger than the preſſure of the air, as is eaſily underſtood from what has been ſaid under ENGINE for extinguiſhing fires, the water being raiſed in a ſimilar manner in both machines; there by the preſſure of condenſed elaſtic air; and here by the preſſure of rarified elaſtic ſteam.

The elaſticity of the ſteam increaſing with its heat, and the ſpace, into which it endeavours to expand itſelf, being as its elaſticity or ſtrength, and ſince we know that water expanded into vapour, of the ſame ſtrength of the air, occupies near 3000 times the ſpace as before, it follows, that, when the ſteam has twice that ſtrength, it will be expanded into 6000; if it be five times as ſtrong as the air's ſpring, it will become expanded into 15000 times that ſpace, and ſo on, beyond the reach of experiments; from all which it appears, how near a perfect vacuum we may approach by this engine, or any other, by means of rarified vapours.

The following engine, which was invented by Mr. De Moura of Portugal, F. R. S. is an improvement of that above deſcribed, as it is rendered capable of working itſelf.

This engine conſiſts of a receiver, a ſteam, and an injection-cock; a ſuction and a forcing-pipe, each furniſhed with a valve; together with a boiler, which, on account of its bulk and weight, was not ſent with the reſt; but, as it may be of the common globular ſhape, and having nothing particular in its conſtruction, a deſcription of it will not be neceſſary, as alſo, the reſt of theſe parts already mentioned being eſſential to every machine of this kind, a further account of them may be diſpenſed with. What is peculiar to this engine, is a float within the receiver, compoſed of a light ball of copper, which is not looſe therein, but faſtened to the end of an arm, which is made to riſe and fall by the float, while the other end of the arm is faſtened to an axis; and conſequently, as the float moves up and down, the axis is turned round one way or the other. This axis is made conical, and paſſes through a conical ſocket; which laſt is ſoldered to the ſide of the receiver. Upon one of the ends of the axis, which projects beyond the ſocket, is fitted a ſecond arm, which is alſo moved backward and forward by the axis, as the float riſes and falls. By theſe means, the riſing and falling of the ſurface of the water within the receiver communicates a correſpondent motion to the outſide, in order to give proper motions to the reſt of the geer, which regulates the opening and ſhutting of the ſteam and injection-cocks; and ſerves the ſame purpoſe as the plug-frame, &c. in Newcomen's engine. The particular conſtruction and relation of thoſe pieces, will better appear by the figure and references, than can be done by a general deſcription.

AB, (p. LII. *fig.* 3.) an arm, which is faſtened to *a b*, a conical axis, which goes through a conical ſocket in C, a triangular piece ſoldered to the receiver. This piece has this ſhape to give liberty to the arm to riſe and fall, that carries the float on the inſide. D E is a ſmall ciſtern ſoldered to the receiver, which, being kept full of water, keeps the axis and ſocket air-tight. This ciſtern is conſtantly kept full of water, by means of a ſmall leakage through the wooden peg *c*, which follows the pack-thread *e d* to the ciſtern.

e, is a ſmall weight to counterpoiſe the float within.

f, is a ſlider, which being ſet nearer to, or farther from, the axis, will riſe or fall a greater or leſſer ſpace, as may be required; and is faſtened by the ſcrew *g*. This ſlider is furniſhed with a turn-about, *h i*, which is alſo faſtened by a ſcrew, and not at the end *i*, and ſerves to adjuſt the length of F G G H, a chain, which gives motion, by means of the ſhorter chain *k l*, to I K L, the balance, which opens and ſhuts the cocks; and moves upon the ſmall axis L.

G, G, are two pullies ſupported by two arms that are faſtened to the ſide of the receiver, and give the chain a proper direction in order to move the balance.

M N is the ſteam-cock; the end N being ſuppoſed to be detached from a pipe that gives it communication with the boiler.

O is the injection-cock, whoſe key is turned by the arm O *m*.

P Q is the injection-pipe, communicating between the forcing-pipe above the valve, and the top of the receiver.

R S is the arm by which the key of the ſteam-cock is worked.

I, K, two rollers annexed to the balance, which is furniſhed with two ſmall rollers, *n*, *o*, which open and ſhut the injection-cock, by acting upon the arm O *m*, in ſuch a manner, that when the ſteam-cock is opened, the injection is ſhut, and *vice verſa*.

T is a bell of advice, which, moving along with the balance, continues to ring as long as the engine is at work.

V is a cock which ſerves to diſcharge the air from the receiver, and is opened by hand when neceſſary.

W is a weight ſufficient to raiſe the balance to a perpendicular poſture, when it is inclined to the right, and alſo to overcome the friction of the float, axis, pullies, chain, &c.

To put the engine in motion, preſs down the arm A B, which will bring the balance over to the right ſide, and in its motion will open the ſteam-cock, and ſhut the injection; ſet open the cock at V, that the air may be diſcharged by the entrance of the ſteam into the receiver. This being done, ſhut that cock, and let go the arm; the weight W will bring over the balance to the left, and in its motion ſhut the ſteam-cock, and open the injection; this preſently condenſing the ſteam into water, in a great meaſure, leaves a vacuum in the receiver. Things remain in this ſituation, till the preſſure of the atmoſphere has cauſed the water to mount through the ſuction-pipe into the receiver, where, as its ſurface riſes, it cauſes the float to aſcend; and, depreſſing the arm A B, raiſes the balance till it has paſſed the perpendicular; and in its deſcent, which is done by its own gravity, the roller K lays hold of the arm R S, again opens the ſteam-cock, and ſhuts the injection. The receiver being now almoſt filled with water, the balance cannot return till the ſurface of the water therein ſubſides, and ſuffers the float to deſcend. This is performed by the elaſticity of the ſteam, which, at the ſame time that it fills the receiver, drives out the water through the forcing-pipe; and when the ſurface is deſcended ſo low as to ſuffer the weight W to bring the balance beyond the perpendicular towards the left, it then falls of its own accord, and, in falling, the roller I lays hold of the arm R S, ſhuts the ſteam-cock, and opens the injection as above.

When the engine is deſired to be ſtopped, obſerve, when the balance lies to the right, to turn round the arm O *m* of the injection-cock, ſo that the tail of the ſteam-

cock

cock may miſs it in the next motion; ſo that at the ſame time that the receiver is filled with ſteam, and the ſteam-cock ſhut, the injection not being opened, the motion will ſtop for want thereof.

In the Philoſophical Tranſactions, N°. 461, there is an account of an improvement made in the ſteam-engine by Mr. Payne, as follows. He has contrived two iron-pots, or veſſels, of a conical form, inverted as repreſented by ABEF, (p. LXIII. *fig.* 3.) on the upper-part of which is fixed a round globular copper-head, about five feet and a half in diameter, as L M N. There is then placed on the inſide a ſmall machine H, called the diſperſer, with ſpouts *a*, *b*, *c*, *d*, *e*, &c. round the ſides fixed to it, and the bottom thereof reſts on a center pin O. In this machine is fixed an upright tube G, with holes at the bottom, and a funnel P on the top to receive a ſpout of water from a conduit-pipe Q, by the ſtop-cock R.

This veſſel being completed, two or more of them are placed in a reverberatory arch for conveying the intenſe heat of a ſtrong fire, the flame of which encompaſſes the iron-veſſels, and keeps them in a red heat during the time of their uſe; at which time the cog-wheel I, being turned by proper machines, whirls the diſperſer about with great velocity, and cauſes the water in it, by a centrifugal force, to fly through the ſpouts, againſt the ſides of the red-hot pots, which immediately converts the greateſt part thereof into vapour, or elaſtic ſteam, which is conveyed by a common pipe and cock to the barrel of the engine, to put the piſton in motion; and the waſte water is conveyed away at bottom, by means of a pipe at C D, with a valve at D to keep out the air.

Mr. Vauloüe's ENGINE, *invented for driving the Piles at Weſtminſter Bridge.*

A. (plate LXIII. *fig.* 4.) The great ſhaft on which are the great wheel and drum.

B. The great wheel with cogs, that turns a trundle-head with a fly to prevent the horſes falling when the ram is diſcharged.

C. The drum on which the great rope is wound.

D. The follower, with a roller at one corner, in which are contained the tongs that take hold of the ram, and are faſtened to the other end of the great rope which paſſes over the pulley, near the upper end of the guides, between which the ram falls.

E. The inclined planes which ſerve to open the tongs, and diſcharge the ram.

F. The ſpiral barrel that is fixed to the drum, on which is wound a rope with a counterpoiſe, to hinder the follower from accelerating, when it falls down to take up the ram.

G. The great bolt which locks the drum to the great wheel.

H. The ſmall lever which has a weight fixed at one end, paſſes through the great ſhaft below the great wheel, and always tends to puſh the great wheel upwards, and locks the drum to the great wheel.

I. The forcing-bar which paſſes through the hollow axis of the great ſhaft, and bears upon the ſmall lever, and has near the upper-end a catch, by which the crooked lever keeps it down.

K. The great lever which preſſes down the forcing-bar, and diſcharges the great bolt, at the time the long end is lifted up by the follower.

L. The crooked lever, one end of which has a roller, which is preſſed upon by the great rope; the other end bears upon the catch of the forcing-bar, during the time the follower is deſcending.

M. The ſpring that preſſes againſt the crooked lever, and diſcharges it from the catch of the forcing-bar, as ſoon as the great rope ſlackens and gives liberty to the ſmall lever to puſh up the bolt.

By the horſe going round, the great rope is wound about the drum, and the ram is drawn up till the tongs come between the inclined planes, when they are opened, and the ram is diſcharged.

Immediately after the ram is diſcharged, the roller which is at one end of the follower, takes hold of the rope that is faſtened to the long end of the great lever, and lifts it up; the other end preſſes down the forcing-bar, unlocks the drum, and the follower comes down by its own weight.

As ſoon as the follower touches the ram, the great rope ſlackens, and the ſpring M diſcharges the crooked lever from the catch of the forcing-bar, and gives liberty to the ſmall lever to puſh up the great bolt, and to lock the drum to the great wheel, and the ram is drawn up again as before.

ENGINEER, or INGINEER, properly ſignifies one ſkilled in the nature of engines in general; but it is commonly applied to an officer who is appointed to inſpect and contrive any attacks, defences, &c. of a fortified place.

ENGLAND, the ſouthern diviſion of Great Britain, ſituated in the Atlantic ocean, between the ſecond degree eaſt and ſixth degree weſt longitude, and between 49 deg. 55 min. and 55 deg. 55 min. north latitude.

There are in England, including Wales, fifty-two counties, two archbiſhoprics, twenty-four biſhoprics, two univerſities, twenty-nine cities, upwards of eight hundred towns, and near ten thouſand pariſhes; ſuppoſed to contain about ſeven million of perſons.

As to the polity, trade, law, civil and religious antiquities, &c. of England, their ſeveral branches are treated of under the articles PARLIAMENT, PRIVY-COUNCIL, COURT, CUSTOM-HOUSE, ADMIRALTY, &c.

New ENGLAND, comprehending the colonies of Maſſachuſets, New Hampſhire, Connecticut, Rhode-Iſland, and Providence Plantation, is ſituated between the 67th and 73d deg. weſt longitude, and between the 41ſt and 45th deg. north latitude.

The provinces into which New-England is divided, have different conſtitutions, and generally different governors, who have a negative voice in the choice of the members who are to ſerve as their council; and beſides, all laws muſt be ſent to Old England to receive the approbation of the crown, and no act of government is valid without the governor's conſent in writing.

ENGLISH, or the ENGLISH-TONGUE, the language ſpoken by the people of England, and, with ſome variation, by thoſe of Scotland, as well as part of Ireland, and the reſt of the Britiſh dominions.

The ancient language of Britain is generally allowed to have been the ſame with the Gaulic, or French; this iſland, in all probability, having been firſt peopled from Gallia, as both Cæſar and Tacitus affirm, and prove by many ſtrong and concluſive arguments, as by their religion, manners, cuſtoms, and the nearneſs of their ſituation. But now we have very ſmall remains of the ancient Britiſh tongue, except in Wales, Cornwall, the iſlands and highlands of Scotland, part of Ireland, and ſome provinces of France; which will not appear ſtrange, when what follows is conſidered.

Julius Cæſar, ſome time before the birth of our Saviour, made a deſcent upon Britain, though he may be ſaid rather to have diſcovered than conquered it; but, about the year of Chriſt forty-five, in the time of Claudius, Aulus Plautius was ſent over with ſome Roman forces, by whom two kings of the Britons, Codigunus and Caractacus, were both overcome in battle: whereupon a Roman colony was planted at Malden in Eſſex, and the ſouthern parts of the iſland were reduced to the form of a Roman province: after that, the iſland was conquered as far north as the Firths of Dumbarton and Edinburgh, by Agricola, in the time of Domitian; whereupon a great number of the Britons, in the conquered part of the iſland, retired to the weſt part called Wales, carrying their language with them.

The greateſt part of Britain being thus become a Roman province, the Roman legions, who reſided in Britain for above two hundred years, undoubtedly diſſeminated the Latin tongue; and the people being afterwards governed by laws written in Latin, muſt neceſſarily make a mixture of languages. This ſeems to have been the firſt mutation the language of Britain ſuffered.

Thus the Britiſh tongue continued, for ſome time, mixed with the provincial Latin, till, the Roman legions being called home, the Scots and Picts took the opportunity to attack and harraſs England: upon which, king Vortigern, about the year 440, called the Saxons to his aſſiſtance, who came over with ſeveral of their neighbours, and having repulſed the Scots and Picts, were rewarded for their ſervices with the iſle of Thanet, and

the whole county of Kent: but growing too powerful, and not being contented with their allotment, diſpoſſeſſed the inhabitants of all the country on this ſide of the Severn: thus the Britiſh tongue was in a great meaſure deſtroyed, and the Saxon introduced in its ſtead.

In the beginning of the ninth century, the Danes invaded England, and getting a footing in the northern and eaſtern parts of the country, their power gradually increaſed, and they became ſole maſters of it in about two hundred years. By this means the ancient Britiſh obtained a tincture of the Daniſh language; but their government, being of no long continuance, did not make ſo great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, in the year 1067, was ſubdued by William the Conqueror, duke of Normandy in France: for the Normans, as a monument of their conqueſt, endeavoured to make their language as generally received as their commands, and thereby rendered the Britiſh language an entire medley.

Thus was the ancient Britiſh language, in a manner, extirpated by the Romans, Danes, and Saxons, and ſucceeded by the Saxon, and after that blended with the Norman French. But, beſides theſe, a change in the language has been effected by two other cauſes. The firſt is that of commerce; for as the inhabitants of Great Britain have been for a long ſeries of years greatly addicted to trade, the names of offices, dignities, names of wares, and terms of traffic, have been introduced, and formed according to the genius of our own tongue. The ſecond is that of learning, from which our tongue has received no ſmall improvement; for, as to the Greek and Latin, the learned have, together with the arts and ſciences, now rendered familiar among us, introduced abundance, nay almoſt all the terms of art in the mathematics, philoſophy, phyſic, and anatomy; and we have entertained many more from the Latin, French, &c. for the ſake of neatneſs and elegancy: ſo that, at this day, our language, which, about 1800 years ago, was the ancient Britiſh, or Welſh, &c. is now a mixture of Saxon, Teutonic, Dutch, Daniſh, Norman, and modern French, embelliſhed with the Greek and Latin. Yet this, in our opinion, is ſo far from being a diſadvantage to the Engliſh tongue, as now ſpoke; for all languages have undergone changes, and do continually participate with each other; that it has ſo enriched it, as now to become the moſt copious, ſignificant, fluent, courteous, amorous, and maſculine language in Europe, if not in the world: this, indeed, was Camden's opinion of it in his time, and Dr. Heylin's in his time: if then the Engliſh tongue, in the opinion of theſe learned authors, deſerved ſuch a character in their days, how much more now, having ſince received ſo conſiderable improvements from ſo many celebrated writers.

ENGRAFTING, or GRAFTING, in gardening. See GRAFTING.

ENGRAILED, or INGRAILED, in heraldry, a term derived from the French, *greſly*, hail; and ſignifying a thing the hail has fallen upon and broke off the hedges, leaving them ragged, or with half rounds, or ſemi-circles, ſtruck out of their edges.

ENGRAVING, the art of cutting on wood, metals, precious ſtones, &c. figures, landſcapes, letters, &c.

ENGRAVING *on Wood*. See the article CUTTING *in Wood*.

ENGRAVING *on Copper*, the making, correſpondently to ſome delineated figure or deſign, ſuch concave lines on a ſmooth ſurface of copper, either by cutting or corroſion, as render it capable, when charged properly with any coloured fluid, of imparting by compreſſion an exact repreſentation of the figure or deſign to any fit ground of paper or parchment.

The method by which engraving is at this time performed, is of three kinds: by the graver or tool alone, which is in common language the only kind called engraving: by corroſion with aqua-fortis, which is generally called etching: and by covering the ſurface of a copper-plate with lines, in ſuch manner, that the whole would produce the effect of black in an impreſſion; and then ſcraping or burniſhing away part of the lines, ſo as to cauſe the remainder to have the ſame effect as if they had been cut on the even ſurface, according to the delineation of any figure or deſign; which laſt kind is called ſcraping in mezzotinto. See ETCHING and MEZZOTINTO.

Engraving with the tool was the kind originally practiſed, and it is yet retained for many purpoſes. For tho' the manœuvre of etching be more eaſy, and other advantages attend it; yet where great regularity and exactneſs of the ſtroke or lines are required, the working with the graver is much more effectual; on which account it is more ſuitable to the preciſion neceſſary in the execution of portraits; as there every thing the moſt minute muſt be made out and expreſſed, according to the original ſubject, without any licenſe to the fancy of the deſigner in deviating from it, or varying the effect either by that maſterly negligence and ſimplicity in ſome parts, or thoſe bold ſallies of the imagination and hand in others, which give ſpirit and force to hiſtory painting.

The principal inſtruments uſed in engraving with the tool, are gravers, burniſhers, an oil-ſtone, and a cuſhion for bearing the plates.

Gravers are made in ſeveral forms with reſpect to the points, ſome being round, others ſquare, and a third kind lozange. The round-pointed is beſt for ſcoring lines; the ſquare for cutting broad and deep; and the lozange for more delicate and fine ſtrokes and hatches. La Boſſe recommends, as the moſt generally uſeful, ſuch as are of a form betwixt the ſquare and lozange; and adviſes, that they ſhould be of a good length; ſmall towards the point, but ſtronger upwards, that they may have ſtrength enough to bear any ſtreſs there may be occaſion to lay upon them; for if they be too ſmall and mounted high, they will bend, which frequently cauſes their breaking, eſpecially if they be not employed for very ſmall ſubjects.

Burniſhes are another kind of inſtruments uſed to aſſiſt in the engraving on ſome occaſions, as well as to poliſh the plates. Thoſe uſed for engraving may be ſuch as are made for other purpoſes; which, being to be procured every where, do not require a further deſcription here. The principal application of them in engraving, beſides their uſe in poliſhing the plates, is to take out any ſcratches, or accidental defacings, that may happen to the plates during the engraving; or to leſſen the effect of any parts that may be too ſtrongly marked in the work, and require to be taken down.

A cuſhion, as it is called, is likewiſe generally uſed for ſupporting the plate in ſuch manner, that it may be turned every way with eaſe. It is a bag of leather filled with ſand, which ſhould be of the ſize that will beſt ſuit the plates it is intended to bear. They are round and about nine inches over, and three or four inches in thickneſs.

The cuſhion, made as above directed, being laid on the table firmly fixed, the plate muſt be put upon it; and the graver being held in the hand, according to the inſtructions before given, the point muſt be applied to the plate, and moved in the proper direction for producing the figures of the lines intended: obſerving, in forming ſtraight lines, to hold the plate ſteady on the cuſhion; and where they are to be finer, to preſs more lightly, uſing greater force where they are to be broader and deeper. In making circular or other curve lines, the hand and graver muſt be held ſteady, with the arm reſting upon the table; and the plate moved upon the cuſhion under the graver, ſo that as each proper part paſſes the point, the figure intended may be cut upon it: for crooked and winding lines cannot be produced with the ſame neatneſs and command by any other means. After part of the work is engraved, it is neceſſary to ſcrape it with the ſharp edge of a burniſher, or graver, paſſed in the moſt level direction over the plate, to take off the roughneſs formed by the cutting of the graver; but great care muſt be taken not to incline the edge of the burniſher, or tool uſed, in ſuch manner, that it may take the leaſt hold of the copper; as it would otherwiſe produce falſe ſtrokes or ſcratches in the engraving: and that the engraved work may be rendered more viſible, it may afterwards be rubbed over with a roll of felt dipped in oil. In uſing the graver, it is neceſſary to carry it as level as poſſible with the ſurface of the plate; for otherwiſe, if the fingers ſlip betwixt them, the line that will be produced, whether curve or ſtraight, will become deeper and deeper in the progreſs of its formation; which entirely prevents

ſtrokes

ſtrokes being made at one cut, that will be fine at their extremities, and larger in the middle; and occaſions the neceſſity of retouching, to bring them to that ſtate. For this reaſon it is very neceſſary for thoſe, who would learn to engrave in perfection, to endeavour, by frequent trials, to acquire the habit of making ſuch ſtrokes both ſtraight and curving, by lightening or ſinking the graver with the hand, according to the occaſion. If after finiſhing the deſign, any ſcratches appear, or any part of the engraving be falſely executed, ſuch ſcratches, or faulty parts, muſt be taken out by the burniſher, and further poliſhed, if neceſſary, by the abovementioned roll; and the plate may be cleanſed as at firſt, by crumbs of bread and chalk, in order that the obliterated part may be reſtored, where there is occaſion, by reingraving it.

The plate being thus engraved, it is proper to take off the edges, by uſing firſt a rough file, and afterwards a ſmoother; and to blunt the corners a little, by the ſame means; after which, the burniſher ſhould be paſſed over the filed places, to take away the ſcorings, that no part of the printing-ink may be retained in them.

ENGRAVING *on precious Stones*, is the repreſenting of figures, or devices, in relievo, or indented, on divers kinds of hard poliſhed ſtones.

The art of engraving on precious ſtones is one of thoſe wherein the ancients excelled; there being divers antique agats, cornelians, and onyx's, which ſurpaſs any thing of that kind the moderns have produced. Pyrgoteles among the Greeks, and Dioſcorides under the firſt emperors of Rome, are the moſt eminent engravers we read of: the former was ſo eſteemed by Alexander, that he forbad any body elſe to engrave his head: and Auguſtus's head, engraven by the latter, was found ſo beautiful, that the ſucceeding emperors choſe it for their ſeal.

All the polite arts having been buried under the ruins of the Roman empire, the art of engraving on ſtones met the ſame fate. It was retrieved in Italy at the beginning of the fifteenth century, when one John of Florence, and after him Dominic of Milan, performed works of this kind no way to be deſpiſed. From that time, ſuch ſculptures became common enough in Europe, and particularly in Germany, whence great numbers were ſent into other countries; but they came ſhort of the beauty of thoſe of the ancients, eſpecially thoſe on precious ſtones; for, as to thoſe on cryſtal, the Germans, and, after their example, the French, &c. have ſucceeded well enough.

In this branch of engraving, they make uſe either of the diamond, or emery.—The diamond, which is the hardeſt, and moſt perfect of all precious ſtones, is only cut by itſelf, or with its own matter. See DIAMOND.

As to rubies, emeralds, hyacinths, amethyſts, garnets, agats, and other of the ſofter ſtones, they are cut on a leaden wheel, moiſtened with emery and water; and poliſhed with tripoli, on a pewter-wheel. Lapis, opal, &c. are poliſhed on a wooden wheel.

To faſhion and engrave vaſes of agat, cryſtal, lapis, or the like, they have a kind of lathe, like that of the pewterers, excepting, that whereas the latter is to hold the veſſels which are to be wrought with proper tools; the former generally holds the tools, which are turned by a wheel, and the veſſel held to them to be cut and engraved, either in relievo, or otherwiſe; remembering, from time to time, to moiſten the tools with diamond duſt and oil, or at leaſt emery and water.

To engrave figures or devices on any of theſe ſtones, when poliſhed, ſuch as medals, or ſeals, &c. they uſe a little iron wheel, the two ends of whoſe axes are received within two pieces of iron placed upright, as in the turner's lathe, to be brought cloſer, or ſet further apart, at pleaſure. At one end of one of the axes are fitted the proper tools, being kept tight by a ſcrew. Laſtly, the wheel is turned by the foot, and the ſtone applied by the hand to the tool; and thus ſhifted and conducted, as occaſion requires.

The tools are generally of iron, ſometimes of braſs. As to their form it is various, but generally bears ſome reſemblance to chiſſels, gouges, &c. ſome have ſmall round heads like buttons, others like ferrels, to take the pieces out; others flat, &c. Theſe tools are not applied directly againſt the ſtone, but, as it were, ſidewiſe; thus wearing, and, as it were, grinding off the ſubſtance: and ſtill, whether it be figures, or letters, or characters, the manner of application is the ſame. The tools, as above obſerved, are to be frequently moiſtened with diamond duſt, and oil of olives. When the ſtone is engraven, they poliſh it on a wheel of bruſhes, made of hogs briſtles, with tripoli. For the larger and leſs delicate works, they have copper or pewter tools, on purpoſe to poliſh the ground, or plain parts, with tripoli, &c. which they apply after the ſame manner as thoſe wherewith the graving is performed.

ENGRAVING *on Steel* is chiefly employed in cutting punches for coins, medals, &c.

The methods of engraving, with the inſtruments, &c. are the ſame for coins, as for medals and counters: all the difference conſiſts in their greater or leſs relievo; the relievo of coins being much leſs conſiderable than that of medals; and that of counters ſtill leſs than that of coins.

The engraver in ſteel uſually begins with punches, or punchions, which are in relievo, and ſerve for making the creux, or cavities of the matrices, and dies. Though, ſometimes, he begins immediately with the creux; but it is only when the intended work is to be cut very ſhallow. The firſt thing is to deſign his figures; then he moulds them in white wax, of the ſize and depth required; and from this wax he graves his punch.

This punch is a piece of ſteel, or at leaſt of iron and ſteel mixed; on which, before they temper or harden it, the intended figure, whether a head, or a reverſe, is cut, or carved in relievo. The inſtruments uſed in this graving in relievo, which are much the ſame as thoſe wherewith the finiſhing of the work in creux is effected, are of ſteel. The principal are gravers of divers kinds, chiſſels, flatters, &c. When the punch is finiſhed, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is ſtruck, to give the impreſſion to the matrice.

What they call matrice, or matrix, is a piece of good ſteel of a cubic form, called alſo a die; whereon the relievo of the punch is ſtruck in creux. It is called matrix, becauſe, in the cavities or indentures thereof, the coins, or medals, ſeem formed, or generated, as animals are in the matrix of their mother. To ſoften this ſteel, that it may more eaſily take the impreſſions of the punch, they make it red-hot; and, after ſtriking the punch thereon in this ſtate, they proceed to touch up or finiſh the ſtrokes and lines, where, by reaſon of their fineneſs, or the too great relievo, they are any thing defective, with ſome of the tools abovementioned.

The figure thus finiſhed, they proceed to engrave the reſt of the medal, as the mouldings of the border, the engrailed ring, letters, &c. All which, particularly the letters, and graining, or engrailment, are performed with little ſteel punches, well tempered, and very ſharp. Add, that as they ſometimes make uſe of punchions, to engrave the creux of the matrix; ſo, on ſome occaſions, they make uſe of the creux of the matrix to engrave the relievo of the punch.

To ſee and judge of the engraving in creux, divers means have been deviſed to take the impreſſions therefrom, as the work proceeds. Sometimes they make uſe of a compoſition of common wax, turpentine, and lamp black; which, always retaining its ſoftneſs, eaſily takes the impreſſion of the part of the graving it is applied to. But, this only ſerving to ſhew the work piece-meal, they have had recourſe to other ways, to ſhew the whole figure. The firſt, by pouring melted lead on a piece of paper, and clapping the matrice thereon: the ſecond, with melted ſulphur, managed the ſame way: and the third, proper only where the graving is ſhallow, by laying a piece of ſoft paper on the graving, and over the paper a leaf of lead; when, giving two or three blows with a hammer on the lead, the paper takes the impreſſion of the work.

When the matrix is quite finiſhed, they temper it, rub it well with pumice-ſtone, and clean out the ſtone again with a hair-bruſh; and, laſtly, poliſh it with oil and emery.

ENGUICHE, in heraldry, is ſaid of the great mouth

of a hunting horn, when its rim is of a different colour from that of the horn itſelf.

ENHARMONIC, in the ancient muſic, one of their genera or kinds of muſic, ſo called from its ſuperior excellence; though wherein it conſiſted, ſays Mr. Malcolm, is hard to ſay: it was allowed by all to be ſo very difficult, that few could ever practiſe it.

Others ſay it is a ſpecies of muſic, the modulation whereof proceeds by intervals leſs than ſemitones; as the ſemitone minor, enharmonic dieſis, and third major.

ENIXUM, among chemiſts, a kind of neutral ſalt, generated of an acid and an alkali.

The ſal enixum of Paracelſus, is the caput mortuum of ſpirits of nitre with oil of vitriol, or what remains in the retort after the diſtillation of this ſpirit, being of a white colour, and pleaſing acid taſte.

ENMANCHE, in heraldry, is when lines are drawn from the center of the upper-edge of the chief to the ſides, to about half the breadth of the chief; ſignifying ſleeved, or reſembling a ſleeve, from the French *manche*.

ENNEAGON, in geometry, a figure conſiſting of nine angles, and as many ſides.

The word is derived from the Greek εννεα, nine, and γονια, an angle.

ENNEAHÆDRIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek εννεα, nine, and εδρα, a ſide.

The bodies of this genus are ſpars, compoſed of nine planes, in a triagonal column, terminated at each end by a triagonal pyramid.

ENNEANDRIA, in botany, a claſs of plants, with hermaphrodite flowers, and nine ſtamina, or male parts, in each.

The word is derived from the Greek εννεα, nine, and ανηρ, male.

The plants of this claſs are the bay-tree, rhubarb, &c.

ENNERIS, in the naval architecture of the ancients, a galley or veſſel with nine tiers of oars. See the article GALLEY.

ENS, among metaphyſicians, denotes entity, being, or exiſtence: this the ſchools call *ens reale*, and *ens poſitivum*, to diſtinguiſh it from their *ens rationis*, which is only an imaginary thing, or exiſts only in the imagination.

ENS, among chemiſts, imports the power, virtue, and efficacy, which certain ſubſtances exert upon our bodies.

ENS VENERIS, the ſublimate of equal quantities of dulcified calx of vitriol, and the dried flowers of ſal ammoniac, a ſmall proportion of which turns a large one of the infuſion of galls black: it is red, ſaline, and aſtringent; and ſaid to be an excellent medicine in diſtempers ariſing from a weakneſs of the ſolids, as the rickets, and the like.

ENSIFORM, in general, ſomething reſembling a ſword; thus we find mention of enſiform leaves, enſiform cartilage, &c.

The word is compounded of the Latin, *enſis*, a ſword, and *forma*, reſemblance.

ENSIGN, in the military art, a banner, under which the ſoldiers are ranged according to the different companies or parties they belong to.

ENSIGN is alſo the officer that carries the colours, being the loweſt commiſſioned officer in a company of foot, ſubordinate to the captain and lieutenant.

ENSIGN, in naval affairs, a ſort of banner or flag hoiſted on a pole called the enſign-ſtaff over the ſtern of a ſhip.

It is uſed to diſtinguiſh the ſhips of different nations from one another, as alſo the different ſquadrons of a fleet from each other. See FLAG and SIGNAL.

ENTABLATURE, or ENTABLEMENT, in architecture, is that part of an order of a column, which is over the capital, and comprehends the architrave, frieze, and corniche.

The entablature is alſo called the trabeation, and ſeems borrowed from the Latin, *trabs*, a beam; though others derive it from *tabulatum*, a ceiling, becauſe the frieze is ſuppoſed to be formed by the ends of the joiſts which bear upon the architrave.

It is different in different orders; for notwithſtanding that it conſiſts of the three beforementioned diviſions in all; yet theſe parts are made up of more or fewer particular members or ſubdiviſions, according as the order is more or leſs rich. Vignola makes the entablature a quarter of the height of the whole column in all the orders. In the Tuſcan and Doric, the architrave, frieze, and corniche, are all the ſame height. In the Ionic, Corinthian, and Compoſite, the whole entablature being of fifteen parts, five of theſe go to the architrave, four to the frieze, and ſix to the corniche. See the articles TUSCAN, DORIC, &c.

Mr. le Clerc obſerves, that were we to regard only the laws of ſtrength and weakneſs, we ſhould rather diminiſh the entablature of ſuch columns as have pedeſtals, than thoſe which have none. As to the projecture of the entablature, it ſhould never be forgot, that its principal deſign is to ſhelter what is underneath.

ENTABLATURE, in maſonry, is uſed ſometimes to denote the laſt row of ſtones on the top of the wall of a building, on which the timber and covering reſt. This is often made to project beyond the naked of the wall, to carry off the rain.

ENTAIL, in law, is a free eſtate intailed; that is, abridged and limited to certain conditions preſcribed by the donor or grantor. See the articles FEE, RECOVERY, and TAIL.

ENTE, in heraldry, a method of marſhalling more frequent abroad than with us, and ſignifying grafted or ingrafted.

ENTELECHIA, εντελεχεια, a word uſed by Ariſtotle to expreſs the ſoul, and which, not occurring in any other author, has given the commentators upon that philoſopher great trouble to diſcover its true meaning.

ENTEROCELE, in ſurgery, is a kind of ſwelling, in which the inteſtine falls into the groin or ſcrotum.

The word is Greek, and derived from εντερον, an inteſtine, and κηλη, a hernia, tumour, or rupture.

This diſorder ariſes from a violent diſtention of the peritonæum and rings of the abdominal muſcles, through which the inteſtine prolapſes into the ſcrotum; and proceeds from ſome violence by a fall, blow, or ſtraining to leap, lift up great weights, vomiting, &c. and according to the nature of the cauſe, the rupture is formed either inſtantly or imperceptibly by degrees. This rupture is always attended with pains, and uſually happens but in one ſide, never in both at a time: ſometimes the inteſtine alone falls down; at other times it is accompanied with the omentum. The tumour appears ſoft to the touch like an inteſtine, or bladder, diſtended with wind: it firſt appears ſmall in the ingueh, and gradually deſcends down to the teſticle of the ſame ſide in the ſcrotum, which is thereby ſometimes diſtended halfway down the thigh, and even down to the knee: the other ſymptoms are the ſame with thoſe of the bubonocele.

The tumour is encreaſed by crying, plentiful eating, lifting, or carrying any burden; is contracted with cold, and dilated with heat: it may be diſtinguiſhed generally from the hydrocele or pneumatocele, by its returning into the abdomen with a murmuring noiſe.

This kind of rupture may be ſuſtained with but little inconveniencies by men not addicted to hard labour, and women with child; but it ſhould never be left to itſelf without a ſupport or truſs, leſt, by ſome accident, the inteſtines ſhould become incarcerated, and incapable of being returned. When the diſorder is recent, and in a young ſubject, it may be perfectly cured without danger of a relapſe; as it may alſo in adults and old people, by conſtantly wearing a proper truſs. It is leſs dangerous when the inteſtine is attended with the omentum. When the inteſtine is returnable, the ſurgeon ſhould immediately reduce the parts, and retain them in their proper ſituation, and to cloſe up the aperture firmly with a truſs, bandage, or by inciſion, termed celotomy.

Another method conſiſts chiefly in paſſing a ſmall gold wire round the upper part of the proceſs of the peritonæum, near the ring of the abdominal muſcles, leaving the teſticle in its natural poſition: the wire is twiſted by a pair of forceps, ſo as to confine the proceſs of the peritonæum, without compreſſing the ſpermatic veſſels, in order to prevent the inteſtine from falling through it

again: this method, however, is not thought effectual in moſt caſes by Heiſter.

In order to preſerve the teſticle, ſome ſurgeons do not tie the proceſs of the peritonæum and ſpermatic veſſels with a ligature, but having returned the inteſtines and omentum, they then ſcarify the ring of the abdomen, through which the inteſtine prolapſed, together with the ſkin, in order to render the cicatrix more firm. If in the interocele the inteſtine cannot be reduced, eſpecially if it adhere to the proceſs of the peritonæum, ring of the abdominal muſcles, ſcrotum, or teſticle, no truſs or bandage will be of any ſervice: there is, then, but one method of ſaving the patient, by a ſevere operation; in order to which the integuments are to be divided; and when the ſacculus appears, it is to be ſeparated, and a ſmall aperture made in it big enough to introduce a quill, or ſome other inſtrument, to ſeparate the inteſtine from all its adheſions, before it is protruded into the abdomen, which ſhould always be done where the inteſtine adheres; after which the wound is to be healed, and the patient ſecured from a relapſe, by wearing the bandage-ſpica. See BANDAGE and TRUSS.

If the ſtricture of the inteſtine is ſo great as to render all means ineffectual to reduce the rupture; the ſurgeon muſt then have recourſe to the knife to ſave the patient.

ENTERO-EPIPLOCELE, in ſurgery, is a kind of rupture in which the inteſtines and omentum, or caul, fall down together into the ſcrotum.

The word is derived from the Greek εντερον, an inteſtine; and επιπλοον, the caul.

ENTERO EPIPLOMPHALUS, in ſurgery, is a rupture cauſed by the inteſtine and caul falling down through the navel.

The word is formed from the Greek εντερον, a gut, επιπλοον, the caul, and ομφαλος, the navel.

This is a diſorder common to women with child.

ENTERO-HYDROMPHALUS, in ſurgery, is when the tumour is cauſed by the gut and water ſwelling out at the navel.

The word is formed from the Greek εντερον, a gut, υδωρ, water, and ομφαλος, the navel.

ENTEROLOGY, a treatiſe on the bowels, which generally includes the contents of the three cavities, the head, breaſt, and belly.

The word is Greek, and derived from εντερον, a gut, and λογος, a diſcourſe.

ENTERPLEADER, in law, ſignifies the diſcuſſing or trial of point, incidentally falling out, before the principal cauſe can be determined.

ENTERSOLE, in architecture, a kind of little ſtory, ſometimes called a mezanzine, contrived occaſionally at the top of the firſt ſtory, for the conveniency of a wardrobe, &c.

ENTERTAINMENT, in a theatrical ſenſe. See the article FARCE.

ENTHUSIASM, a tranſport of the mind, whereby it is led to think and imagine things in a ſublime, ſurpriſing, and yet probable manner.

The word is Greek ενθουσιασμος, and derived from ενθουσιαζω, to be agitated with divine raptures.

ENTHUSIASM, in a religious ſenſe, implies a tranſport of the mind, whereby it fancies itſelf inſpired with ſome revelation, impulſe, &c. from heaven.

There is a degree of aſſent, ſays Mr. Locke, which, with ſome men, has the ſame authority, as either faith or reaſon; and that is Enthuſiaſm; which, laying by reaſon, would ſet up revelation without it; whereby, in effect, it takes away both reaſon and revelation, and ſubſtitutes, in the room of it, the ungrounded fancies of a man's own brain, and aſſumes them for a foundation both of opinion and conduct.

Immediate revelation being a much eaſier way for men to eſtabliſh their opinions, and regulate their conduct by, than the tedious labour of ſtrict reaſoning; it is no wonder, that ſome have been very apt to pretend to it, eſpecially in ſuch of their opinions and actions as they cannot account for by the ordinary methods of knowledge, and principles of reaſon.

Hence we ſee, that, in all ages, men, in whom melancholy has mixed with devotion; or whoſe conceit of themſelves has raiſed them into an opinion of greater familiarity with God, than is allowed others; have often flattered themſelves with the perſuaſion of an immediate intercourſe with the Deity, and frequent communications from the divine ſpirit.

Their minds being thus prepared, whatever groundleſs opinion comes to ſettle itſelf ſtrongly upon their fancies, is an illumination from the ſpirit of God; and, whatſoever odd action they find in themſelves an inclination to do, that impulſe is concluded to be a call, or direction, from heaven, and muſt be obeyed. This we take to be properly Enthuſiaſm, which, though riſing from the conceit of a warm or overweening brain, works, where its once gets footing, more powerfully on the perſuaſions and actions of men, than either reaſon, or revelation, or both together; men being moſt forwardly obedient to the impulſes they receive from themſelves.

When men are once got into this way of immediate revelation, of illumination without ſearch, and certainty without proof, reaſon is loſt upon them; they are above it: they ſee the light infuſed into their underſtandings, and they cannot be miſtaken; like the light of bright ſun-ſhine, it ſhews itſelf, and needs no other proof but its own evidence: they feel the hand of God moving them within, and the impulſes of the ſpirit, and cannot be miſtaken in what they feel.—But, of this ſeeing and feeling, is it a perception of an inclination to do ſomething, or of the ſpirit of God moving that inclination? Theſe are two very different perceptions, and ſhould be carefully diſtinguiſhed.

If they know the thing to be a truth, they muſt do it, either by its own ſelf-evidence, or by the rational proofs that make it out to be ſo: if they know it to be a truth either of theſe two ways, they in vain ſuppoſe it to be a revelation: for thus all truths, of what kind ſoever, that men uninſpired are enlightened with, come into their minds. If they ſay, they know it to be true, becauſe it is a revelation from God, the reaſon is good; but then it will be demanded, how they know it to be a revelation from God? If they ſay, by the light it brings with it; they ſhould conſider, whether this be ſaying any more, than that it is a revelation, becauſe they believe it to be true; for all the light they ſpeak of, is but a ſtrong perſuaſion of their own minds, that it is a truth; which is a very unſafe ground to proceed on, either in our tenets or actions. True light in the mind is nothing elſe but the evidence of the truth of any propoſition: and, if it be not ſelf-evident, all the light it can have, is from the clearneſs of thoſe proofs upon which it is received.

God, when he makes the prophet, doth not unmake the man; he leaves his faculties in their natural ſtate, to enable him to judge of his inſpirations, whether they be of divine original, or no. If he would have us aſſent to the truth of any propoſition, he either evidences that truth by the uſual methods of natural reaſon, or elſe makes it known to be a truth which he would have us aſſent to by his authority; and convinces us, that it is from him, by ſome marks, which reaſon cannot be miſtaken in.

The holy men of old, who had revelations from God, had ſomething elſe beſides internal light of aſſurance in their own minds, to teſtify to them that it was from God. They had outward ſigns to convince them, of the author of thoſe revelations. And, when they were to convince others, they had a power given them to juſtify the truth of their commiſſion from heaven; and by viſible ſigns to aſſert the divine authority of the meſſage they were ſent with. Moſes ſaw the buſh burn without being conſumed, and heard a voice out of it. God, by another miracle, of his rod turned into a ſerpent, aſſured him likewiſe of a power to teſtify his miſſion, by the ſame miracle repeated before them to whom he was ſent.

ENTHUSIAST, a perſon poſſeſſed with enthuſiaſm.

ENTHYMEME, ενθυμημα, among logicians, denotes a ſyllogiſm, perfect in the mind, but imperfect in the expreſſion, by reaſon one of the propoſitions is ſuppreſſed, as being eaſily ſupplied by the underſtanding of thoſe

thoſe with whom we diſcourſe: as for example, *Every man is mortal; therefore every king is mortal*; where the minor propoſition, *every king is a man*, is omitted as being ſufficiently known.

There is a particular elegance in the enthymeme form of arguing, as leaving ſomewhat to the exerciſe and invention of the mind; for which reaſon it is very frequent, as well in common converſation, as in the moſt polite writers. It not only ſhortens diſcourſe, and adds a certain ſtrength and livelineſs to our reaſoning, but alſo gives the reader a pleaſure not unlike that the author himſelf feels in compoſing. By this means we are put upon exerting ourſelves, and ſeem to ſhare in the diſcovery of what is propoſed to us.

ENTIER, in the manege, a reſty horſe that not only refuſes to turn, but alſo reſiſts the hand.

ENTIERTY, or ENTIERTIE, among lawyers, implies the whole of a thing, in contradiſtinction to a moiety: thus a bond, damages, &c. are ſaid to be intire, when they cannot be apportioned.

ENTIRE TENANCY, in law, is when the ſole poſſeſſion is in one perſon, in contradiſtinction to ſeveral tenancy, which is a joint, or common poſſeſſion of two or more.

ENTITIVELY, and ENTIETY, among metaphyſicians; ſee ENS.

ENTOYER, in heraldry, denotes a border charged wholly with things without life: it ſeems to be a corruption of the French *entour*, round about.

ENTREPAS, in the manege, a broken pace or going that is neither walk nor trot, but has ſomewhat of an amble.

ENTROCHUS, in natural hiſtory, the name of a genus of foſſils, of a very regular figure and ſtructure, ſuppoſed, by many authors, to be lapides ſui generis, and ſtones in their native ſtate. They are, however, in reality, the foſſil remains of ſome marine animal, probably either of the echinus, or of the ſtar-fiſh kind, filled, like the foſſil ſpecies of the echini, with a plated ſpar. Our imperfect knowledge in the animal hiſtory has not yet been able to aſcertain to what creature they really belong; but their analogy with the other animal remains found in the foſſil world, plainly evince, that they are of that origin. They are cylindric columns, uſually about an inch in length, and are made up of a number of round joints, like ſo many ſmall wheels, or ſegments of cylinders. Theſe joints, when found ſeparate, and naturally looſe, as they ſometimes are, are called trochitæ. They are all ſtriated, from the center to the circumference, and have a cavity in their middle, which is ſometimes found empty, but more frequently filled up with various matter, of the nature of the ſtratum in which they have lain, or of ſome other native foſſil ſubſtance.

ENTRY, in law, ſignifies taking poſſeſſion of lands or tenements, where a perſon has a right ſo to do. It is alſo uſed for a writ of poſſeſſion.

Bill of ENTRY, in commerce. See BILL.

ENVELOPE, in fortification, a work of earth, ſometimes in form of a ſimple parapet, and at others, like a ſmall rampart with a parapet; it is raiſed ſometimes on the ditch, and ſometimes beyond it.

Envelopes are often made to incloſe a weak ground, where that is practicable, with ſingle lines, to ſave the great charge of horn-works and tenails, or where there is not room for ſuch large works. Some give the name of ſillon, counterguard, conſerve, and lunette, to envelopes raiſed in the moat.

ENVIRONNE, in heraldry, ſignifies ſurrounded with other things: thus, they ſay, a lion environné with ſo many bezants. See the article BEZANT.

ENUMERATION, an account of ſeveral things, in which mention is made of every particular article.

ENUMERATION, in rhetoric, a part of peroration, in which the orator, collecting the ſcattered heads of what has been delivered throughout the whole, makes a brief and artful relation, or recapitulation thereof.

ENVOY, a perſon deputed to negociate ſome affair with any foreign prince or ſtate.

ENURNY, in heraldry, is applied to a border charged with beaſts.

ENVY, in ethics, is defined to be an uneaſineſs of the mind, cauſed by the conſideration of a good we deſire, obtained by one we think leſs worthy of it than ourſelves. See the article PASSION.

EPACTS, in chronology, the exceſſes of the ſolar month above the lunar ſynodical month, or of the ſolar year above the lunar year of 12 ſynodical months.

The common lunar year of 12 ſynodical lunations conſiſts of but 354 days, 8 hours, 48 min. 57 ſec. whereas the ſolar or tropical year conſiſts of 365 days, 5 hours, 48 min. 57 ſec. it is plain therefore that the ſolar year exceeds the lunar by 10 days, 21 hours, 00 min. 19 ſec. and in the ſpace of about 33 years, the beginning of the lunar year will have moved through all the variety of ſeaſons, whence it is called the moveable lunar year; and this form of the year is at this time uſed by the Turks and Arabs.

Hence, as the Julian year is 365 days, 6 hours, and the lunar year as above only 354 days, 8 hours, 48 min. 57 ſec. the annual epact will be 10 days, 21^h $11'$ $22''$; that is, nearly 11 days. Conſequently, the epact of 2 years is 22 days; of 3 years, 33 days; or rather 3, ſince 30 days is an emboliſmic, or intercalary month.

Thus, the epact of 4 years is 14 days, and ſo of the reſt; and at the end of every 19^{th} year, the epact becomes 30 or 0; conſequently the 20^{th} year the epact is 11 again; and ſo the cycle of epacts expires with the golden number, or lunar cycle of 19 years, and begins again with the ſame.

Again, as the new moons are the ſame, that is, as they fall on the ſame day every 19 years, ſo the difference between the lunar and ſolar years is the ſame every 19 years: and becauſe the ſaid difference is always to be added to the lunar year, in order to adjuſt, or make it equal to the ſolar year; hence the ſaid difference reſpectively belonging to each year of the moon's cycle is called the epact of the ſaid year, that is, the number to be added to the ſaid year, to make it equal to the ſolar, the word being formed from the Greek επαγω, *induco, intercalo.*

Upon this mutual reſpect between the cycle of the moon, and the cycle of the epacts, is founded this rule for finding the epact belonging to any year of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be leſs than 30, it is the epact ſought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact according to the Julian account.

But as a ſynodical month or ſpace of time contained between the moon's parting from the ſun, at a conjunction, and returning to him again, is 29 days, 12 hours, 44 min. and 6 ſec. it follows, that 235 lunations are made in 6939 days, 16 hours, 43 min. 30 ſec. but in 19 Julian years are 6939 days, 18 hours; and, conſequently, the new moons, after 19 Julian years, will not return to the ſame hour of the day, but will happen 1 hour, 16 min. 30 ſec. ſooner.

And therefore, becauſe the new moons do not return at the ſame time of the day that they did 19 years before; but in 312 years they will anticipate one day: we muſt, in order to find the epact according to the Gregorian calendar, make proper allowance for the anticipation ſince the Nicene council which was held in 325.

To do this, divide the centuries of the propoſed year by 4; let the quotient be multiplied by 43, and the remainder by 17; to the ſum of theſe products add 86, and divide the whole by 25. Let the quotient (neglecting fractions) be ſubtracted from 11 times the prime or golden number, then will the remainder, rejecting thirties, be the epact required.

To find the epact until the year 1900, the following rule will ſerve:

Subtract one from the prime or golden number, multiply the remainder by 11, and, rejecting thirties as before, the remainder will give the epact.

Example.

Example. Let it be required to find the epact for the preſent year 1765.

By the firſt rule

7 = the epact as before.

EPANORTHOSIS, in rhetoric, a figure by which a perſon corrects, or ingeniouſly revokes, what he juſt before alledged, as being too weakly expreſſed, in order to add ſomething ſtronger and more conformable to the paſſion with which he is agitated.

The epanorthoſis is diſtinguiſhed into two kinds: the one is when we correct or revoke the word, as in the following example of the apoſtle, "But I laboured more "abundantly than they all: yet not I, but the grace of "God, which was with me;" 1 Cor. xv. 10. where what he firſt attributed to his own merit, he chooſes afterwards to call the work of grace, as being the principal cauſe. The ſecond kind of epanorthoſis, is when we correct or revoke the ſentiment, as in the following inſtance from Cicero: *Italiam ornare, quam domum ſuam, maluit: quanquam, Italia ornata, domus ipſa mihi videtur ornatior.*

EPARER, in the manege, ſignifies the flinging of a horſe, or his yerking and ſtriking with his hind legs. See YERK.

EPAULE, in fortification, denotes the ſhoulder of a baſtion, or the place where its face and flank meet, and form the angle called the angle of the ſhoulder. See the article BASTION.

EPAULEMENT, in fortification, a work raiſed to cover ſidewiſe, is either of earth, gabions, or faſcines, loaded with earth. The epaulements of the places of arms for the cavalry, at the entrance of the trenches, are generally of faſcines mixed with earth.

EPAULEMENT alſo denotes a maſs of earth, called likewiſe a ſquare orillon from its figure, raiſed to cover the cannon of a cazemate, and faced with a wall.

It is likewiſe uſed for any work, thrown up to defend the flank of a poſt, or other place.

EPEMBOLE, in rhetoric, the ſame with parembole. See the article PAREMBOLE.

EPENTHESIS, in grammar, the interpoſition or inſertion of a letter or ſyllable in the middle of a word, as *olituum*, for *altum*; *relligio*, for *religio*; *induperator*, for *imperator*, &c.

EPHA, or EPHAH, in Jewiſh antiquity, a meaſure for things dry, containing 1.0961 of a buſhel. See MEASURE.

EPHEDRA, the ſea-grape, or ſhrub horſe-tail, in botany, a genus of plants, which has no corolla or flower-petals: the ſtamina are ſeven filaments, coaleſcing into a ſubulated column; the antheræ are roundiſh, three being ſuperior, and the other four inferior: the ſeeds are acutely oval, convex on one ſide, and plane on the other, and contained in a baccated cup.

The fruit is red, ſucculent, and of an acid auſtere taſte: its juice, taken in wine, is ſaid to be good for the coeliac paſſion and fluor albus.

EPHEMERA, in medicine, the name of a ſpecies of fever continuing the ſpace of one day, or ſometimes more; for the medical writers expreſs themſelves by *ephemera ſimplex, vel plurium dierum.*

This ſpecies of fever has this peculiar to it, that the pulſe is at firſt large, but as it becomes afterwards moderately quick and frequent, ſo it is equal, ſoft, and regular, as in a natural ſtate. The urine undergoes little or no change, nor is the diſorder preceded by a loathing of food, a ſpontaneous laſſitude of the body, diſturbed ſleep, preternatural yawning, or horror; but it ſeizes the patient ſuddenly, and afflicts him with no other ſymptoms than a pain of the head and ſtomach, a nauſea, heat, and reſtleſſneſs. The perſons moſt ſubject to this fever, are young men who have much blood, and feed heartily, and ſuch as have had any habitual diſcharge of blood ſtopped upon them, whether natural, as in the hæmorrhoidal or menſtrual diſcharges, or artificial, ſuch as frequent bleeding, cupping, and the like; and thoſe who have thrown their blood into violent emotions by the too free uſe of ſpirituous liquors, too violent exerciſe, unuſual watchings, long ſtay by large fires, a ſudden repreſſion of ſweats by cold water, or by violent paſſions, particularly anger. In the treatment of this fever, the proper courſe is to attemperate the violent motions of the blood with nitrous and the fixed antimonial medicines, and occaſionally with gentle acids. Sweat is to be promoted. Nitre, crabs-eyes, &c. may be preſcribed in ſmall doſes every three or four hours; and towards night, ſudorifics ſhould be joined to theſe, ſuch as the contrayerva-root, or the like. The ephemera, properly ſo called, differs in nothing except the time of its duration, from that which commonly laſts four days.

EPHEMERA MALIGNA is alſo a term by which ſome authors have called the ſudor anglicanus, or malignant diary fever, which generally deſtroyed the patient in twenty-four hours. See the article SUDOR ANGLICANUS.

EPHEMERA, the day-fly, in zoology, a genus of flies belonging to the neuroptera order, and ſo called from their living only one day and a night: they are about the ſize of the leſſer houſe-flies, and have two gibbous protuberances on the top of the head, reſembling eyes; add to this, that the tail is furniſhed with hairs, and the antennæ are ſhort.

Of this genus there are ſeveral ſpecies, diſtinguiſhed by their different colours, and the number of hairs in their tail; ſome having two, and others three.

EPHEMERIDES, in literary hiſtory, an appellation given to thoſe books or journals, which ſhew the motions and places of the planets for every day of the year.

It is from the tables contained in theſe ephemerides, that eclipſes, and all the variety of aſpects of the planets, are found. See the articles ECLIPSE, CONJUNCTION, OPPOSITION, &c.

EPHIPPUIM, in anatomy, the ſame with the cella turcica, being a part of the os ſphenoides. See the article SPHENOIDES.

EPHOD, in Jewiſh antiquity, one part of the prieſtly habit; being a kind of girdle which, brought from behind the neck over the two ſhoulders, and hanging down before, was put croſs the ſtomach, then carried round the waiſt, and made uſe of as a girdle to the tunic.

There were two ſorts of ephods, one of plain linen for the prieſts, and the other embroidered for the high prieſt: of this laſt Moſes gives an ample deſcription. It was compoſed of gold, blue, purple, crimſon, and twiſted cotton. Upon part of it, which paſſed over the ſhoulders, were two large precious ſtones, one on each ſhoulder: upon theſe were engraven the name of the twelve tribes, ſix upon each ſtone.

The ephod was peculiar to the prieſthood, and thought eſſential to their character; it being the opinion of the Jews, that no worſhip, true or falſe, could ſubſiſt without a prieſthood and ephod.

EPHORI, ἔφοροι, in Grecian antiquity, magiſtrates eſtabliſhed

eſtabliſhed in ancient Sparta to balance the regal power.

EPIC, or HEROIC POEM, a diſcourſe formed upon a ſtory partly real and partly feigned, repreſenting ſome one glorious and fortunate action, that is diſtinguiſhed by a variety of wonderful, yet probable and pleaſing events, and delivered in verſe by way of narration, in a ſublime and flowing ſtile, to form the manners, and inflame the mind with the love of virtue.

What diſtinguiſhes an epic from a dramatic poem, is, its being a narration that comes immediately from the poet, and is not repreſented as a tragedy by perſons introduced for that purpoſe.

The chief things to be conſidered in an epic poem are, firſt, the fable, that is, the form, and artful repreſentation of the action, which is the matter of the poem; and as the action is more or leſs perfect, ſo is the fable. The action in an epic poem, as well as in tragedy, muſt be one, not all the actions of a perſon's life; becauſe the mind is better ſatisfied with the contemplation of a ſingle object that is eaſily underſtood, than when it is perplexed with a variety, and loſt in confuſion. And on this principal action muſt all the epiſodes or under-actions ſo depend, as to become different, yet uſeful, members of the ſame body, and contribute to its ſupport. It muſt likewiſe be entire, that is, complete in all its parts, or, as Ariſtotle deſcribes it, have a beginning, a middle, and an end. Nothing ſhould go before, be intermixed with, or follow after this main action, but what is related to it; nor ſhould any ſingle ſtep be omitted in that juſt and regular proceſs, which it muſt be ſuppoſed to take from its origin to its conſummation. The epic action ought alſo to be great, that it may ſtrike us with awe, and be ſuitable to the dignity of the princes, heroes, and illuſtrious perſons, who are ſuppoſed to be ſpeaking and acting in the poem. It ſhould likewiſe be intereſting, that it may engage our paſſions and affections; and entire, that the mind may be wholly ſatisfied. As to its duration, it is not circumſcribed within any limited time; but the warmer and more violent the action is, the ſhorter muſt be its continuance. Thus the Iliad, whoſe ſubject is the anger of Achilles, contains only forty-ſeven days; but the Æneid, whoſe hero is of a quite different character, takes up a much longer time.

The manners and ſentiments fall under the ſame rule as thoſe of tragedy: and as to the diction, it ought to be perſpicuous, but at the ſame time figurative, noble, and ſublime. See TRAGEDY.

The moderns ſeem to miſtake that part of the epic and tragedy which contain the wonderful, confounding it with improbable, and uſing the two words promiſcuouſly. If it was really ſo, the wonderful would be always faulty; for that is always ſo which is improbable. The great art is a juſt temperament and mixture of both, to make it natural and probable. Scarce any of the poets but Virgil had the art, by the preparation of incidents, to manage the probability in all the circumſtances of an epic poem. Homer is not altogether ſo ſcrupulous and regular in his contrivances: his machines are leſs juſt, and all his meaſures, to ſave the probability, are leſs exact. Laſtly, the ſovereign perfection of an epic poem, in the opinion of Ariſtotle, conſiſts in the juſt proportion and perfect connection of all the parts. It is not ſufficient that all be grand and magnificent in an epic poem, but all muſt be juſt, uniform, and proportionable, in the different parts that compoſe it.

This is all that can be obſerved moſt eſſential to an epic poem: little need be ſaid about the machinery, which, among the ancient heathens, was the agency of their falſe gods, and of angels and dæmons among us chriſtians: its beauty and magnificence is well known. The dignity of an epic poem would ſcarce be kept up without it, eſpecially ſince the marvellous depends on it. The verſification of epic poetry, among the Greeks and Romans, conſiſted of hexameters, a ſort of verſe ſo peculiar to the epic, that when it is uſed upon other occaſions, it is called heroic verſe. Our Engliſh verſe comes neareſt to it both in gravity and majeſty, but at how great a diſtance? See the article HEXAMETER.

An epic or heroic poem is the beſt and moſt perfect kind of poetry; it is the greateſt work which the ſoul of man is capable of performing; and here it is the utmoſt bounds are ſet to human compoſition. All the nobleneſs and the elevation of the moſt perfect genius can hardly ſuffice to form ſuch a one as is requiſite for an heroic poet: the difficulty of finding together fancy and judgment, heat of imagination and ſobriety of reaſon, precipitation of ſpirit, and ſolidity of mind, renders this character ſo very rare: it requires great images, and yet a greater wit to form them. There muſt be a judgment ſo ſolid, a diſcernment ſo exquiſite, ſuch perfect knowlege of the language in which he writes, ſuch obſtinate ſtudy, profound meditations, and vaſt capacity, that ſcarce whole ages can produce one genius fit for an epic poet: even among the ancients themſelves, if we except Homer and Virgil, we ſhall ſcarce find one that is truly an epic poet.

EPICARPIUM, in ancient pharmacy, denotes a remedy applied in form of a plaſter to the wriſts: it conſiſted of penetrating ingredients, as garlic, onion, camphor, &c.

EPICEDIUM, ἐπικήδιον, in ancient poetry, a poem rehearſed during the funeral ſolemnity of perſons of diſtinction. See the article NENIA.

EPICERASTICA, ἐπικερασικὰ, from κεράννυμι, to mix, or attemperate. Medicines which attemperate or obtund the acrimony of the humours, and mitigate the uneaſy ſenſation of the parts thence ariſing. Among medicines of this kind, are reckoned emollient roots; as thoſe of the marſh-mallow, mallow, and liquorice.

The leaves of mallows, water-lily, the large houſe-leek-purſlane, and lettuce.

The ſeeds of barley decorticated, white henbane, lettuce, flax, white poppy, and rue.

The fruits, jubebs, raiſins, ſweet apples, ſweet prunes, ſebeſtens, ſweet almonds, and pine-nuts.

Among juices and liquors; almond-milk, ſtarch, barley-water, pinguious broths, the milk of the ſow-thiſtle, cremor of ptiſan, and the juices of the leaves of night-ſhade, and winter-cherry.

Among the parts of animals; the whites of eggs, butter, milk of all kinds, whey; the head and the feet of a calf, and alſo a ſheep's head, and broths prepared of them; jellies of hartſhorn and ivory.

Among mucilages; the ſeed of fleawort, quinces, of the ſeed and root of marſh-mallows; of the ſeed of flax, mallows, and of the root of borrage.

Among oils; oil of olives, violets, ſweet almonds, expreſſed oils of the ſeed of gourd, white henbane, and white poppy.

Among ointments; the unguentum roſatum and unguentum album camphoratum.

Among ſyrups; the ſyrups of violets, of apples, of marſh-mallows, of Fernelius, of liquorice, jubebs, poppies, and of purſlane.

Among the various ſhop preparations; the pulp of caſſia, diacodium, diapenidium, ſugar of violets, julap of violets, honey of violets.

EPICHIREMA, ἐπιχείρημα, in logic, a mode of reaſoning, which comprehends the proof of one or both the premiſes of a ſyllogiſm, before the concluſion is drawn.

EPICOENE, in grammar, a term applied to nouns, which, under the ſame gender and termination, mark indifferently the male and female ſpecies.

EPICUREAN PHILOSOPHY, the doctrine or ſyſtem of philoſophy maintained by Epicurus and his followers.

Epicurus, the Athenian, one of the greateſt philoſophers of his age, was obliged to Democritus for almoſt his whole ſyſtem, notwithſtanding he piqued himſelf upon deriving every thing from his own fund. He wrote a great number of books, which are made to amount to above 300. Though none of them are come down to us, no ancient philoſopher's ſyſtem is better known than his, for which we are moſtly indebted to the great Lucretius, Diogenes Laertius, and Tully.

His philoſophy conſiſted of three parts, canonical, phyſical, and etherial. The firſt was about the canons, or rules of judging. The cenſure which Tully paſſes upon him for his deſpiſing logic, will hold true only with regard to the logic of the ſtoics, which he could not approve of, as being too full of nicety and quirk. Epicurus was not

not acquainted with the analytical method of diviſion and argumentation, nor was he ſo curious in modes and formation as the ſtoics. Soundneſs and ſimplicity of ſenſe, aſſiſted with ſome natural reflections, was all his art. His ſearch after truth proceeded only by the ſenſes, to the evidence of which he gave ſo great a certainty, that he conſidered them as an infallible rule of truth, and termed them the firſt natural light of mankind.

In the ſecond part of his philoſophy he laid down atoms, ſpace, and gravity, as the firſt principles of all things: he did not deny the exiſtence of a God, but thought it beneath his majeſty to concern himſelf with human affairs: he held him a bleſſed, immortal being, having no affairs of his own to take care of, and above meddling with thoſe of others. See ATOMICAL PHILOSOPHY.

As to his ethics, he made the ſupreme good of man to conſiſt in pleaſure, and conſequently ſupreme evil in pain. Nature itſelf, ſays he, teaches us this truth, and prompts us from our birth to procure whatever gives us pleaſure, and avoid what gives us pain. To this end he propoſes a remedy againſt the ſharpneſs of pain: this was to divert the mind from it, by turning our whole attention upon the pleaſures we have formerly enjoyed: he held that the wiſe man muſt be happy, as long as he is wiſe; that pain, not depriving him of his wiſdom, cannot deprive him of his happineſs.

There is nothing that has a fairer ſhew of honeſty than the moral doctrine of Epicurus. Gaſſendus pretends, that the pleaſure in which this philoſopher has fixed the ſovereign good, was nothing elſe but the higheſt tranquility of mind in conjunction with the moſt perfect health of body: but Tully, Horace, and Plutarch, as well as almoſt all the fathers of the church, give us a very different repreſentation: indeed the nature of this pleaſure, in which the chief happineſs is ſuppoſed to be ſeated, is a grand problem in the morals of Epicurus. Hence there were two kinds of Epicureans, the rigid and the remiſs: the firſt were thoſe who underſtood Epicurus's notion of pleaſure in the beſt ſenſe, and placed all their happineſs in the pure pleaſures of the mind, reſulting from the practice of virtue. The looſe or remiſs Epicureans, taking the words of that philoſopher in a groſs ſenſe, placed all their happineſs in bodily pleaſures, or debauchery. Thus we have the whole myſtery of this celebrated doctrine. It was innocent in expreſſion, but criminal in thought; it had a beautiful outſide, but it was all corruption within. Theſe looſe philoſophers took up a ſeeming auſterity to diſguiſe their ſecret indulgence, and all their ſchemes of morality were but ſo many veils for their immoral behaviour.

EPICYCLE, in the Ptolemaic aſtronomy, is a little circle whoſe center is in the circumference of a greater; or it is a ſmall orb, which, being fixed in the large orb of a planet, is carried along with it, and yet by its own peculiar motion carries the body of the planet round its proper center. This ancient aſtronomers aſcribed to all the planets, except the ſun, in order to ſolve their phœnomena.

EPICYCLOID, in geometry, is a curve generated by a point taken in the periphery of a circle, that revolves upon the periphery of any other circle, either within or without it.

A point of the circumference of a circle, proceeding along a plane, in a right line, and at the ſame time revolving on its center, deſcribes a cycloid.

And the generating circle, if, inſtead of moving on a right line ſhould, move along the circumference of another circle, whether equal or unequal, the curve deſcribed by any point in its circumference is called an epicycloid.

If the generating circle proceed along the convexity of the periphery, it is called an upper or exterior epicycloid: if along the concavity, a lower or interior epicycloid.

The length of any part of the curve, that any point in the revolving circle has deſcribed from the time it touched the circle it revolved upon, ſhall be to double the verſed ſine of half the arch, which all that time touched the circle at reſt, as the ſum of the diameters of the circles, to the ſemi-diameter of the reſting circle; if the revolving circle move upon the convex ſide of the reſting circle; but if upon the concave ſide, as the difference of the diameters to the ſemi-diameter.

Dr. Halley gives a general propoſition for the meaſuring of all cycloids and epicycloids: thus, The area of a cycloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle; and alſo the areas of the parts, generated in thoſe curves, to the areas of analogous ſegments of the circle; as the ſum of double the velocity of the center, and velocity of the circular motion, to the velocity of the circular motion. The demonſtration hereof, ſee in the Phil. Tranſact. N°. 218.

EPIDEMIA, ἐπιδήμια, in Grecian antiquity, feſtivals kept in honour of Apollo and Diana, at the ſtated ſeaſons when theſe deities, who could not be preſent every where, were ſuppoſed to viſit different places, in order to receive the vows of their adorers.

The feſtival took its name epidemia, from ἐπὶ, among, and δῆμος, people; on account of the imaginary preſence of thoſe deities among the people.

EPIDEMIA is alſo uſed for the private feaſts, or rejoicings, on account of the ſafe return of a friend from a voyage or journey.

EPIDEMIC, among phyſicians, an epithet of diſeaſes, which, at certain times, are popular; attacking great numbers at or near the ſame time.

EPIDEMIC diſeaſes differ from thoſe called endemic. See the article ENDEMIC.

We muſt remark, ſays the celebrated Boerhaave, that though every particular diſeaſe of the fluids, in various epidemical conſtitutions, appear, to inattentive obſervers, the ſame with regard to their names, ſigns, and their conſequences in ſome meaſure, yet the ſame diſeaſes, appearing in one epidemical conſtitution, differ exceedingly from thoſe produced in another, with reſpect to their obſcure natures; their appearances not obſervable, except by the judicious; the various times of their increaſe, ſtate, coction, criſis, effect, event, and method to be purſued for the cure. Hence it is evident, that they require a different adminiſtration of the non-naturals, different treatment and medicines: this variety, however, in epidemical diſtempers is ſo obſcure, that phyſicians have not yet been able to deduce it from any abuſe of the non-naturals: and yet there are many circumſtances which make it highly probable, that the cauſes reſide in the air, but depend more upon the inexplicable variety of exhalations contained therein, which, by their mixture with the fluids of the body, or their ſtimulus, injure the human machine, than upon any change in the ſenſible qualities thereof. But it is very ſurpriſing, that theſe epidemical diſorders ſhould be principally propagated by contagion, received from one by another perſon unaffected.

Upon the invaſion of any unknown epidemical diſtemper, the phyſician will receive ſome information with reſpect to the cure, firſt, by reducing the diſtemper to ſome more known ſpecies, which it moſt reſembles.

Secondly, by obſerving its tendency at the vernal and autumnal equinoxes, at which ſeaſons it is generally moſt prevalent.

Thirdly, by attending to the ſpontaneous phœnomena which precede, accompany, or follow, the death or recovery of the patient, and the better or worſe ſtate of the diſorder.

Fourthly, by diligently remarking the benefit or injury received, from whatever the patients are unavoidably obliged to do; whatever is taken into, or diſcharged out of the body.

Fifthly, by comparing the caſes of a great many patients labouring under the diſtemper at the ſame time.

Sixthly, by abſtaining from all remedies which are dubious, which exagitate and induce a conſiderable change in the humours, and thereby obſcure the genus of the diſeaſe.

From theſe circumſtances, duly attended to, the curative indication ariſes.

EPIDERMIS, in anatomy, the ſame with the cuticle. See the article CUTICLE.

EPIDIDYMIS, in anatomy, the name by which ſome call the two bodies more uſually known by that of paraſtatæ. See the article PARASTATÆ.

EPIGASTRIC Region, a part or ſubdiviſion of the abdomen. See Abdomen.

Epigastric Veſſels, the arteries and veins belonging to the epigaſtric region; the former being branches of the cœliac artery, and the latter of the iliac veins. See Artery and Vein.

EPIGLOTTIS, in anatomy, one of the cartilages of the larynx, or wind-pipe. It is often of the ſhape of an ivy-leaf, and joined to the thyroide cartilage; over which it appears erect, immediately behind the root of the tongue; to which it is alſo connected by its middle ligament by two lateral ones to the cornua of the os hyoides, and by two poſterior ones to the arytenoide cartilage. In the act of ſwallowing it covers the glottis, or aperture of the larynx, and prevents any thing getting into it. See the articles Larynx and Glottis.

EPIGRAM, in poetry, a ſhort poem, or compoſition in verſe, treating of one thing only, and whoſe diſtinguiſhing characters are brevity, beauty, and point.

The word epigram ſignifies inſcription; for epigrams derive their origin from thoſe inſcriptions placed by the ancients on their ſtatues, temples, pillars, triumphal arches, and the like; which, at firſt, were very ſhort, being ſometimes no more than a ſingle word, but afterwards, increaſing their length, they made them in verſe to be the better retained by the memory. This ſhort way of writing came at laſt to be uſed upon any occaſion or ſubject; and hence the name of epigram has been given to any little copy of verſes, without regard to the original application of ſuch poems.

Its uſual limits are from two to twenty verſes, though ſometimes it extends to fifty; but the ſhorter the better it is, and the more perfect, as it partakes more of the nature and character of this kind of poem: beſides, the epigram, being only a ſingle thought, ought to be expreſſed in a little compaſs, or elſe it loſes its force and ſtrength.

The beauty required in an epigram, is an harmony and apt agreement of all its parts, a ſweet ſimplicity, and polite language.

The point is a ſharp, lively, unexpected turn of wit, with which an epigram ought to be concluded. There are ſome critics, indeed, who will not admit the point in an epigram, but require the thought to be equally diffuſed through the whole poem, which is uſually the practice of Catullus, as the former is that of Martial. It is allowed, there is more delicacy in the manner of Catullus, but the point is more agreeable to the general taſte, and ſeems to be the chief characteriſtic of the epigram.

This ſort of poem admits of all manner of ſubjects, provided that brevity, beauty, and point, are preſerved; but it is generally employed either in praiſe or ſatire.

Though the beſt epigrams are ſaid to be ſuch as are compriſed in two or four verſes, we are not to underſtand it as if none can be perfect which exceed thoſe limits. Neither the antients nor moderns have been ſo ſcrupulous with reſpect to the length of their epigrams; but, however, brevity in general is always to be ſtudied in theſe compoſitions.

EPILEPSY, επιλημψια, in medicine, the ſame with what is called the falling-ſickneſs, from the patient's falling ſuddenly to the ground.

Sometimes this diſeaſe comes upon the patient unawares; but it more frequently gives notice of its approach, by a laſſitude of the whole body, a heavy pain in the head, with ſome diſturbance of the ſenſes, unquiet ſleep, unuſual dread, dimneſs of ſight, and a noiſe in the ears: in ſome there is a violent palpitation of the heart, a puffing or inflation of the breaſt, difficult reſpiration, a murmuring noiſe in the belly, fœtid ſtools, a flux of the urine, and a refrigeration of the joints: in others, there is a ſenſation as it were of cold air, aſcending from the extreme parts towards the brain and heart. At length, falling ſenſeleſs to the ground, the thumbs are ſhut up cloſe in the palms of the hands, and are with difficulty taken out; the eyes are diſtorted or inverted, ſo as nothing but the whites appear: all ſenſation is ſuſpended, inſomuch that no ſmell, no noiſe, nor even pinching of the body is able to bring them to themſelves: they froth at the mouth with a hiſſing kind of noiſe; the tongue is lacerated, or torn by the teeth, and there is a ſhaking or trembling of the joints. However, in different patients the ſymptoms vary; for ſometimes, inſtead of convulſive motions, the limbs are all ſtiff, and the patient is as immoveable as a ſtatue: in infants the penis is erected; and in young men, there is an emiſſion of the ſemen, and the urine ſometimes ſtreams out to a great diſtance. At laſt there is a remiſſion of the ſymptoms, and the patients come to themſelves after a longer or ſhorter interval; then they complain of a pain and heavineſs of the head, and a laſſitude of all their joints.

Theſe fits uſually return on certain days, or age of the moon, but eſpecially about the new or full moon; in women, chiefly about the time of menſtruation, and as to the prognoſtics they generally leave the patient about the time of puberty.

As to the cure, in adults, or grown perſons, it is extremely difficult; but in children, it is juſt the reverſe. Blifters laid on the back part of the head are of great uſe a little before the fit is expected; which may the more certainly be foreknown, as this diſeaſe is influenced by the moon. The moſt proper medicines to correct the juices ſeem to be native cinnabar, and wild valerian root; a dram of which may be taken morning and evening for three or four months, and afterwards two or three days before the new and full moon. Or, two ſcruples of the powder of wild valerian root, mixed with one of that of native cinnabar, may be taken morning and evening. Ambergriſe and muſk are alſo accounted excellent.

It muſt not however be forgot, that this diſeaſe owes its origin to ſo many different cauſes, and is bred in ſo many different conſtitutions of the body, that the ſame remedy which ſucceeds in one caſe, often fails in another; and, therefore, different medicines are to be tried, eſpecially in adults. In caſe of a plethora, bleeding in the ancles will be proper. If the humours be in fault, cathartics, iſſues, cauteries, and blifters muſt be uſed. If in children it proceeds from gripes, or the breeding of teeth, nothing is better than to cleanſe the belly by milk clyſters, with a little venice-ſoap diſſolved in them. Some epileptic powder with cinnabar, or extract of rhubarb, and made into an electuary with ſyrup of roſes and manna, may likewiſe be given in proper doſes.

During the fit, too free an uſe of volatiles, ſpirituous liquors, and ſtrong ſmells, are hurtful, as cauſing the humours to flow too much to the head. The beſt method is to place the patient in an erect poſture, and to rub the hands and feet pretty briſkly; and the beſt drink is pure water, which will mitigate, if not cure, the ſymptoms.

When the diſeaſe is cauſed by external violence, or extravaſations of humours in the head, cinnabar reduced into an impalpable powder, and given in large doſes with other cephalics and diaphoretics, has a kind of ſpecific virtue.

According to Dr. Cheyne, a milk-diet will cure the moſt inveterate epilepſy. Miſletoe is alſo ſaid to cure it, as ſure as the bark does an intermitting fever: its doſe, to grown people, is half a dram or more, in powder, to be taken every ſixth hour, drinking after it a draught of a ſtrong infuſion of the ſame plant; and if to every ounce of the powder, a dram of aſa-fœtida be added, the medicine will be ſtill more effectual. Cinnabar of antimony is alſo greatly celebrated for the cure of this diſeaſe, and may be taken from four grains to a ſcruple, in conſerve of roſemary-flowers. If the diſeaſe is inveterate, ſome adviſe to give the following pills for a month, viz. Take caſtor and gum ammoniac, of each eight grains; wild valerian-root, half a ſcruple; ſalt of tartar, ſeven grains; and as much of tincture of caſtor as is ſufficient to form them into pills, one of which makes a doſe. On every ſeventh day, a cathartic ſhould be given; and ſometimes, inſtead of the caſtor and gum, filings of ſteel may be ſubſtituted.

A decoction of guaiacum, or ſaſſafras, taken twice a day, ſix or eight ounces at a time, and continued for thirty or forty days, is alſo ſaid to cure the epilepſy; eſpecially if male piony-root, or the like, be added.

The following electuary is alſo recommended as a moſt excellent and certain anti-epileptic: Take of Peruvian bark, pulveriſed, ſix drams; of Virginia ſnake-root, likewiſe

wiſe pulveriſed, two drams; and of the ſyrup of piony-flowers, as much as is ſufficient to make a ſoft electuary. The doſe, after proper evacuations, in adults, is a dram; which ſhould be taken morning and evening for three or four months; and afterwards only repeated three or four days before the new and full moon.

EPILOBIUM, in botany, the willow-herb, a genus of plants, the corolla whereof conſiſts of four roundiſh patent petals, ſomewhat emarginated: the fruit is a very long capſule of a cylindraceous form, ſtriated, made up of four valves, and containing four cells: the ſeeds are numerous, oblong, and crowned with down.

EPILOGUE, in oratory, the end or concluſion of a diſcourſe, ordinarily containing a recapitulation of the principal matters delivered. See PERORATION.

EPILOGUE, in dramatic poetry, a ſpeech addreſſed to the audience after the play is over, by one of the principal actors therein, uſually containing ſome reflections on certain incidents in the play, eſpecially thoſe in the part of the perſon that ſpeaks it.

The epilogue is but of modern date, much later than the prologue: ſeveral have taken the exodium of the Greek drama for an epilogue; but it appears that they are very different; as the exodium was the laſt of the four parts of the tragedy, containing the unravelling the plot, anſwering to the laſt act of modern tragedy.

In the modern tragedy the epilogue has uſually ſomewhat of pleaſantry, intended, in all probability, to compoſe the paſſions raiſed in the courſe of the repreſentation. This is ridiculed by the Spectator, and compared to a merry jigg upon the organ, after a good ſermon, to wipe away any impreſſions that might have been made thereby, and ſend the people away juſt as they came. This practice, however, has the countenance of antiquity, for the Romans had ſomething of the ſame nature, though under a different name; but their exodium was a kind of farce or pantomime, brought on the ſtage when the tragedy was over, to compoſe the minds of the audience.

EPIMEDIUM, barren wort, in botany, a genus of plants, whoſe characters are as follow.

The leaves are like thoſe of ivy, and grow three on the top of each branch: the ſtalk is divided into three branches at each joint, and the triple diviſion is continued in the ſubdiviſions: the calyx is compoſed of four leaves: the flower conſiſts of four petals, which are tubulated and hollowed into blind canals, and furniſhed with four ſtamina: the ovary is ſeated in the bottom of the calyx, and is furniſhed with an erect tube or pointal, which becomes an unicapſular bivalve pod, containing round flat ſeeds.

EPINICION, in the Greek and Latin poetry, denotes a poem or compoſition on occaſion of a victory obtained. It alſo ſignifies a rejoicing, or feſtival, on account of a victory.

EPIPHANY, a Chriſtian feſtival, otherwiſe called the Manifeſtation of Chriſt to the Gentiles, obſerved on the ſixth of January, in honour of the appearance of our Saviour to the three magi, or wiſe men, who came to adore him and bring him preſents. The feaſt of Epiphany was not originally a diſtinct feſtival, but made a part of that of the nativity of Chriſt, which being celebrated twelve days, the firſt and laſt of which were high or chief days of ſolemnity, either of theſe might properly be called epiphany, as that word ſignifies the appearance of Chriſt in the world.

The kings of England and Spain offer gold, frankincenſe, and myrrh, on epiphany, or twelfth day, in memory of the offerings of the wiſe men to the infant Jeſus.

The feſtival of epiphany is called by the Greeks the feaſt of lights, becauſe our Saviour is ſaid to have been baptized on this day; and baptiſm is by them called illumination.

EPIPHONEMA, in rhetoric, a ſententious exclamation, containing a lively remark placed at the end of a diſcourſe or narration; ſuch is that of Virgil.

Fas omne abrumpit, Polydorum obtruncat, & auro
Vi potitur. Quid non mortalia pectora cogis
Auri ſacra fames?

And that of Lucretius, lib. i.

Tantum relligio potuit ſuadere malorum!

This figure cloſes a narration in a very advantageous manner, deeply impreſſes the thing related upon the memory of the reader, and leaves him well pleaſed with the ſenſe and ſagacity of his author.

EPIPHORA, in medicine, a preternatural defluxion of the eyes, when they continually diſcharge a ſharp ſerous humour, which excoriates the cheeks. The cure is performed by a derivation of the offending humour elſewhere, by bleeding, cupping, bliſters, purges, &c. The acrimony is likewiſe to be corrected by bitter chalybeate wine: ſometimes wine drank alone will perform the cure; after which, aſtringent topics are to be made uſe of. See the article RHEUM.

If an epiphora has been of long ſtanding, it is difficult to be cured, and often degenerates into a fiſtula lachrymalis. See the article FISTULA LACHRYMALIS.

EPIPHYLLOSPHERMOUS PLANTS, the ſame with capillary ones. See CAPILLARY.

EPIPHYSIS, in anatomy, a bony ſubſtance, or as it were a leſſer bone affixed to a larger or principal bone, by the intervention of a cartilage. In young people theſe epiphyſes are not continuous to the principal bone, but are only connected by the intermediate cartilage, and hence they are called appendages to the bones. It is to be obſerved of epiphyſes, 1. That they are all cartilaginous in infants; and though they afterwards grow hard, yet they never arrive at the true denſity of a bone. 2. That moſt of them degenerate into apophyſes in adults. 3. That they do not grow along the plain ſurface of the bone, but unequally, or by a mutual ingreſs with the body of it.

The uſe of the epiphyſes is very different in adults and in infants: in adults they ſeem to ſerve the bones which contain large quantities of marrow, by way of operculum, that this ſoft matter may not run out. 2. They are of ſervice to the articulators, rendering the motions more eaſy, as well as more determinate. 3. They make the whole bone lighter than it would be, if their place were ſupplied by abſolute bony matter. 4. They increaſe the power of the muſcles about the tendons, by means of their prominences. 5. They add to the ſize of the places deſtined for receiving the inſertions of the muſcles. 6. They give a firmer coheſion to the ligaments which ſerve in the articulations, and allow an entrance to the blood-veſſels. The uſes of the epiphyſes in infants are, 1. That by means of their yielding ſoftneſs, they may give way to the compreſſion in the uterus, and ſuffer the whole bulk to be more folded together than otherwiſe it could, ſo that it may lie in a ſmaller compaſs. 2. That they may give way to the elongation and growth of the bones. 3. That they may prevent the frequent fractures, which would otherwiſe unqueſtionably happen to children from their falls, and the other accidents they are liable to.

EPIPLOCELE, in medicine, is a kind of hernia, or rupture, in which the omentum ſubſides into the ſcrotum. The cure conſiſts principally in a reduction of the tumour, by returning the omentum again into the abdomen, and in ſecuring the parts from a relapſe by a truſs or bandage. See HERNIA and ENTEROCELE.

EPIPLOIS, in anatomy, a term applied to the arteries and veins diſtributed through the ſubſtance of the epiploon or caul: thus, the dextera epiplois is a branch of the right ſide of the cæliac artery, and the ſiniſtra epiplois and gaſtro-epiplois are terms by which anatomiſts call branches from the left ſide of the cæliac artery. See the articles CÆLIAC and ARTERY.

EPIPLOOMPHALON, *επιπλοομφαλον*, in medicine, an hernia umbilicalis, proceeding from the omentum falling into the region of the umbilicus or navel. See the article EXOMPHALUS.

EPIPLOON, the ſame with what is otherwiſe called omentum. See OMENTUM.

EPIPLOSARCOMPHALUS, in ſurgery, a kind of exomphalus. See the article EXOMPHALUS.

EPISCOPACY, the quality of epiſcopal government, or that form of church diſcipline, wherein dioceſan biſhops are eſtabliſhed diſtinct from and ſuperior to prieſts or preſbyters. See BISHOP.

EPISCOPAL, ſomething belonging to biſhops. See the articles BISHOP and EPISCOPACY.

EPISCOPALIANS, in church-hiſtory, an appellation given

given to those who prefer the episcopal government and discipline to all others.

EPISODE, ἐπεισόδιον, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events: though, in a more limited sense, all the particular incidents whereof the action or narration is compounded, are called episodes. See the articles EPIC and TRAGEDY.

The episode, in its original, was only something rehearsed between the parts of the chorus, or antient tragedy, for the diversion of the audience. Episodes serve to promote the action, to illustrate, embellish, and adorn it, and carry it to its proper period. Episodes are either absolutely necessary, or very requisite. All episodes are incidents, though all incidents are not episodes; because some incidents are not adventitious to the action, but make up the very form and series of it. Examples will clear up this distinction: the storm in the first Æneid of Virgil, driving the fleet on the coast of Carthage, is an incident, not an episode, because the hero himself and the whole body of his forces are concerned in it; and so it is a direct and not a collateral part of the main action. The adventures of Nisus and Euryalus, in the ninth Æneid, are episodes, not incidents, i. e. not direct parts of the main action.

It is particularly by the art of episodes that the great variety of matter which adorns a poem is brought into the principal action: but though the episodes are a kind of digression from the subject, yet they ought to have a natural relation to the principal action, never be farfetched, and must be handled with judgment, to avoid confusion and burdening the subject with too much action. Without this restriction the episode is no longer probable, and there appears an air of affectation which becomes ridiculous. Aristotle calls all those fables episodic, which abound in episodes not necessarily nor properly connected with each other.

The most natural episodes are the propereſt to circumstantiate the principal actions, namely, the causes, the effects, the beginnings, and the consequences of it. Homer and Virgil have shewn their principal art in this particular: the action of the Iliad and that of the Æneid were in themselves exceeding short, but are so beautifully lengthened and diversified by the intervention of episodes, that they make up an agreeable story, sufficient to employ the memory without overcharging it. See the article EPIC.

Our noble poet Milton has excelled in this art; he has no other episodes than what naturally arise from the subject, and yet his poem of Paradise Lost is filled with a multitude of astonishing incidents. Those great actions, the battle of the angels, and the creation of the world, are by way of episode to this noble poem. With the like art, and in the same manner, in that part of it which regards the fall of man, he has related the fall of those angels who are his professed enemies; besides the many other beauties of such an episode, its running parallel with the great action of the poem, hinders it from breaking unity so much as another episode would have done, that had not so great an affinity with the principal subject.

EPISPASTIC, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part. See VESICATORY.

EPISTLE, ἐπιστολὴ, denotes the same with a missive letter; but is now chiefly used in speaking of antient writings, as the epistles of St. Paul, epistles of Cicero, epistles of Pliny, &c. See the article LETTER.

EPISTOLARY, something belonging to an epistle. The art of epistolary writing is acknowledged to be very entertaining and instructive. The Romans ranked it in the number of liberal and polite accomplishments. And, indeed, it enters so much into all the occasions of life, that no gentleman can avoid shewing himself in this kind of composition; the chief excellence of which consists in expressing ordinary occurrences, in an elegant and uncommon manner. However, it is proper to observe, that such is the nature of epistolary writings, in general, as unavoidably renders them obscure, since the writer passes by many things, as being well known to him to whom the letter is addressed, which must be laid open to a stranger, before he can fully comprehend what is said. Hence it is, that the epistles of the antients, whether sacred or prophane, are so difficult to be understood.

EPISTROPHE, in rhetoric, a figure, wherein that which is supposed of one thing, is strongly affirmed of another: thus, "Are they Hebrews? so am I. Are "they Israelites? so am I. Are they of the seed of "Abraham? so am I," &c.

EPISTYLE, in the antient architecture, a term used by the Greeks for what we call architrave, viz. a massive piece of stone or wood, laid immediately over the capital of a column. See ARCHITRAVE and COLUMN.

EPITAPH, a monumental inscription, which generally contains some elogium of the virtues and good qualities of the deceased, and has a turn of seriousness and gravity adapted to the nature of the subject. The elegance of epitaphs consists in a nervous and expressive brevity; and sometimes are closed with an epigrammatic point. In these compositions, no mere epithet, properly so called, should be admitted; for here illustration would impair the strength, and render the sentiment too diffuse and languid. Words that are synonimous are also to be rejected.

Though the true characteristic of the epitaph is seriousness and gravity, yet we find many that are jocose and ludicrous; some likewise have true metre and rhyme, while others are between prose and verse, without any certain measure, though the words are truly poetical, and the beauty of this last sort is generally heightened by an apt and judicious antithesis.

EPITASIS, in antient poetry, the second part or division of a dramatic poem, wherein the plot, entered upon in the first part, or protasis, was carried on, heightened and worked up till it arrived at its state or height, called catastasis. See PROTASIS, CATASTASIS, DRAMA, &c.

In the epitasis, accidents, as they are called by the moderns, arise; all things are in confusion, and involved in doubts and difficulties. Vossius says, the epitasis is contained in the second, sometimes in the third and fourth, but very rarely any part of it in the fifth act: but Dr. Trapp says, that there is no act to which the epitasis is not suitable; nay, that some of it ought always to be in the fifth act.

It is the epitasis that supports the weight and burden of the poem; upon it the crisis of the action chiefly turns. This division of tragedy is laid aside in the modern drama, instead of which plays are divided into acts. See the article ACT.

EPITASIS, in medicine, the increase of a disease, or beginning of a paroxysm, particularly in a fever. See FEVER.

EPITHALAMIUM, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

EPITHEM, in pharmacy, a kind of fomentation, or remedy of a spirituous aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperature thereof. See the article FOMENTATION.

There are principally three kinds of these external applications, the liquid, the solid, and the soft or poultice-kind. The liquid epithems are sometimes considerably thick; but when they are intended to penetrate deep, they are much better if very thin and fluid. As to the part to which the epithem is immediately applied, it is not what it is always intended to act upon, as this frequently lies deep within: the epithems, therefore, intended for this purpose, should consist of the most penetrating ingredients, for which reason astringents and inspissating remedies can be of no use; but in this form hot wine alone is sometimes used as an epithem, and often such medicines as are not to be safely taken inwardly, such as highly rectified spirits, preparations of lead, henbane, mandrake, and other poisonous plants, and the like: but we are carefully to remember in regard to these, that the pores are capable of absorbing them, and ought therefore to know the effects they are

capable of producing, when thus abſorbed in the body. As to the vehicle of the liquid epithems, they are various, as linen or woollen cloths, ſilk, ſtripes, toaſted bread, &c. They are in ſome caſes to be applied hot, in others, cold; when the intention is to reſolve, penetrate, and attract, then the hot are to be preferred; but theſe are injurious to parts conſtricted by intenſe cold.

The dry epithems are medicated powders, uſually ſewed up in a cloth, and applied to different parts of the body; for which purpoſe the powders muſt be coarſe. Sometimes the liquid epithems are added to the dry, to reduce the whole to a conſiſtence, ſuch as may be ſpread upon cloth, and applied.

EPITHET, in poetry and rhetoric, an adjective expreſſing ſome quality of a ſubſtantive to which it is joined; or ſuch an adjective as is annexed to ſubſtantives by way of ornament and illuſtration, not to make up an eſſential part of the deſcription. Nothing, ſays Ariſtotle, tires the reader more than too great a redundancy of epithets, or epithets placed improperly; and yet nothing is ſo eſſential in poetry as a proper uſe of them. The writings of the beſt poets are full of them, eſpecially Virgil.

EPITOME, in literary hiſtory, an abridgement or ſummary of any book, particularly of a hiſtory. See ABRIDGEMENT.

EPITRITUS, in proſody, a foot conſiſting of three long ſyllables and one ſhort. Of theſe, grammarians reckon four kinds; the firſt conſiſting of an iambus and ſpondee, as *sălūtāntēs*: the ſecond of a trocheus and ſpondee, as *cōncĭtāti*: the third, of a ſpondee and an iambus, as *cōmmūnĭcāns*: and the fourth, of a ſpondee and trocheus, as *incāntārĕ*. See the articles SPONDEUS, TROCHEUS, &c.

EPITROPE, in rhetoric, a Greek term for the ſame figure which the Latins call *conceſſio*. See the article CONCESSION.

EPIZEUXIS, in rhetoric, a figure which repeats the ſame word, without any other intervening: ſuch is that of Virgil; *nunc, nunc, inſurgite remis.*

EPOCHA, in chronology, a term or fixed point of time, whence the ſucceeding years are numbered or accounted. See the article ÆRA.

The moſt remarkable epochas are thoſe that follow.

EPOCHA *of the creation of the world.* See the article CHRONOLOGY.

EPOCHA *of the deluge.* According to the Hebrew text, there are 1656 years from the creation to the deluge; 1307, according to the Samaritan; 2242, according to Euſebius and the Septuagint; 2256, according to Joſephus and the Septuagint; 2262, according to Julius Africanus, Petavius, and the Septuagint; and 2255, according to Jackſon. In following the Hebrew text, this epocha begins in the year 2366 of the Julian period.

EPOCHA *of the Olympiads*, uſed principally by the Greeks, had its origin from the Olympic games, which were celebrated at the beginning of every fifth year. This epocha begins 776 years before the incarnation, or in the 3938 of the Julian period.

Varronian EPOCHA *of the building of Rome*, is fixed 753 years before our Saviour's birth, and in the 3961 of the Julian period.

EPOCHA *of Nabonaſſar king of Babylon*, made uſe of by Ptolemy, Cenſorinus, and ſeveral other authors, began 747 years before the incarnation, and in the 3967 of the Julian period.

Julian EPOCHA. The firſt year of Julius Cæſar's correcting the calendar ſtands 45 years before our Saviour's birth, and coincides with the 4669 of the Julian period.

EPOCHA *of Chriſt.* The chriſtian world generally reckoned from the epocha of the creation, the building of Rome, the conſuls regiſter, or the emperor's reign, till about 500 years after Chriſt, when the epocha of the nativity of our bleſſed Lord was introduced by Dionyſius Exiguus. He began his account from the conception or incarnation, properly called Lady-day. Moſt countries in Europe, however, at preſent reckon from the firſt of January next following, except the court of Rome, where the epocha of the incarnation ſtill obtains for the date of their bulls and briefs. But here we are to obſerve, that there are different opinions touching the year of our Saviour's birth. Capellus and Kepler fix it at about the 748th year from the building of Rome. Deckar and Petavius place the incarnation in the 749th of Rome. Scaliger and Voſſius make it fall on the 751ſt of Rome. Dionyſius Exiguus, Bede, &c. fix the birth of our Saviour to the year 751 of Rome; the diverſity of theſe opinions proceeding from the difficulty of fixing Herod the Great's death, who, as is evident from the Evangeliſts, was living at our Saviour's birth, the taxation of Cyrenius, and the time of our Saviour's beginning his miniſtry. But let this be as it will, it is generally agreed, that as to computation and uſe, the common epocha is to be followed, which places the birth of Chriſt in the 4713 of the Julian period, although the true birth rather correſponds with the 4711th of the ſame period.

Dioclefian EPOCHA, or EPOCHA *of martyrs*, called alſo the æra of the Copthi or Egyptians, becauſe the emperor Diocleſian made a great many martyrs in Egypt, begins in the year 283 of our Lord, and the 4997 of the Julian period.

EPOCHA *of the hegira*, or flight of Mahomet, uſed among the Turks, is the year of the Julian period 5335, anſwering to the year of Chriſt 622.

Yezdejerd, or *Perſian* EPOCHA, is the year of the Julian period 5345, anſwering to the year 622.

To reduce the years of one epocha to thoſe of another, obſerve the following rule: add the given year of an epocha to the year of the Julian period correſponding with its riſe, and that will give the year of the period.

EPODE, in lyric poetry, the third or laſt part of the ode, the ancient ode being divided into ſtrophe, antiſtrophe, and epode. See ODE, &c.

The epode was ſung by the prieſts, ſtanding ſtill before the altar, after all the turns and returns of the ſtrophe and antiſtrophe, and was not confined to any preciſe number or kind of verſes.

The epode is now a general name for all kinds of little verſes that follow one or more great ones, of what kind ſoever they be; and in this ſenſe a pentameter is an epode after an hexameter. And as every little verſe, which being put after another, cloſes the period, is called epode; hence the ſixth book of Horace's odes is entitled, *Liber Epodon*, Book of Epodes, becauſe the verſes are all alternately long and ſhort, and the ſhort ones generally, though not always, cloſe the ſenſe of the long one.

EPOMIS, in anatomy, a muſcle, otherwiſe called deltoides. See DELTOIDES.

EPOPOEIA, in poetry, the ſtory, fable, or ſubject treated of in an epic poem. See FABLE.

The word is commonly uſed for the epic poem itſelf. See EPIC POEM.

EPULONES, in Roman antiquity, miniſters who aſſiſted at the ſacrifices, and had the care of the ſacred banquet committed to them.

EQUABLE, an appellation given to ſuch motions as always continue the ſame in degree of velocity, without being either accelerated or retarded.

EQUAL, a term of relation between two or more things of the ſame magnitude, quantity, or quality.

EQUALITY, that agreement between two or more things, whereby they are denominated equal.

The equality of two quantities, in algebra, is denoted by two parallel lines placed between them: thus, $4+2=6$, that is, 4 added to 2, is equal to 6.

EQUANIMITY, in ethics, denotes that even and calm frame of mind and temper, under good or bad fortune, whereby a man appears to be neither puffed up, or overjoyed with proſperity; nor diſpirited, ſoured, or rendered uneaſy by adverſity.

EQUANT, ÆQUANT, or *Circle of* EQUALITY, in aſtronomy, is a circle uſed in the Ptolemaic ſyſtem to account for the eccentricity of the planets, &c.

EQUATION, or ÆQUATION, in algebra, an expreſſion of the ſame quantity, in two different, that is, diſſimilar, but equal terms or denominations.

As, when we ſay $2\times3=4+2$, that is, twice three is equal to four and two.

Stifelius defines equation to be the ratio of equality between two quantities differently denominated; as when

we

we ſay, 3 ſhill. = 36 pence. Or, 50 ſhill. = 2 *l.* 10 *s.* 50 ſhill. = 600 pence = 2400 farths. Or, $b = d + e$. Or, $12 = \frac{40-4}{3}$, &c.

Hence, the reduction of two heterogeneous, or diſſimilar quantities to the ſame value, i. e. to an equality, is called the bringing them to an equation.

The character or ſign of an equation is =.

The reſolution of problems by means of equations, is the buſineſs of algebra.

Terms of an EQUATION are the ſeveral quantities, or parts, of which an equation is compoſed, connected together by the ſigns + and —. Thus, in the equation $b + c = d$; the terms are b, c, and d, and the tenor or import of the equation is, that ſome quantity, repreſented by d, is equal to two others repreſented by b and c.

Root of an EQUATION is the value of the unknown quantity in the equation. Thus if $a^2 + b^2 = x^2$, the root x will be $\sqrt{a^2 + b^2}$. See ROOTS *of Equations*.

Simple EQUATION is that wherein the unknown quantity is only of one dimenſion, or in the firſt power, as $x = a + b$.

Quadratic EQUATION is that wherein the unknown quantity is of two dimenſions, or in the ſecond power, as $x^2 = a^2 + b^2$. See QUADRATIC *Equation*.

Cubic EQUATION is that wherein the unknown quantity is of three dimenſions, as $x^3 = a^3 - b^3$, &c. See CUBIC *Equation*.

If the unknown quantity be of four dimenſions, as $x^4 = a^4 - b^4$, the equation is called biquadratic; if of 5, a ſurſolid, &c.

In order to bring problems to an equation, the algebraiſt muſt ſubſtitute ſome letter of the alphabet for the unknown quantity; and if there be more unknown quantities than one, the reſt muſt receive their names from ſo many conditions of the problem; and if the problem be juſtly ſtated and examined, there will ſtill remain a condition at laſt, which, being tranſlated into the algebraic language, will afford him an equation, the reſolution whereof will give the unknown quantity for which the tranſlation was made; and when this unknown quantity is once diſcovered, the reſt will be eaſily found. To illuſtrate this by an inſtance: ſuppoſe it required to find three numbers, in continual proportion, whoſe ſum is 20, and the ſum of their ſquares 140. Putting x, y, z, for the names of the three numbers ſought, the queſtion will be tranſlated out of the verbal to the ſymbolical expreſſion, thus:

The queſtion in words.	In ſymbols.
Required three numbers, on theſe conditions.	x. y. z.
That they be continually proportional.	$x : y :: y : z$, or $xz = yy$.
That the ſum be 20.	$x + y + z = 20$.
And the ſum of their ſquares 140.	$x^2 + y^2 + z^2 = 140$.

Thus is the queſtion brought to theſe equations, viz. $xz = yy$, $x + z + y = 20$, and $x^2 + y^2 + z^2 = 140$; by the help whereof x, y, and z, may be found.

The ſolutions of queſtions are, for the moſt part, ſo much the more expedite and artificial, by how much the unknown quantities you have at firſt are the fewer. Thus, in the queſtion propoſed, putting x for the firſt number, and y for the ſecond, $\frac{yy}{x}$ will be the third continual proportional; which being put for the third number, bring the queſtion into equations, as follows:

The queſtion in words.	Symbolically.
There are ſought three numbers in continual proportion.	x, y, $\frac{yy}{x}$
Whoſe ſum is 20.	$x + y + \frac{yy}{x} = 20$
And the ſum of their ſquares 140.	$x^2 + y^2 + \frac{y^4}{x^2} = 140$.

You have therefore the equations $x + y + \frac{yy}{x} = 20$, and $x^2 + y^2 + \frac{y^4}{x^2} = 140$; by reduction whereof x and y are to be determined.

Take another example: A merchant increaſes his eſtate annually by one third part, abating 100 l. which he ſpends yearly in his family; and after three years he finds his eſtate doubled. Query, What is he worth? — To reſolve this, it muſt be obſerved, that there are (or lie hid) ſeveral propoſitions, which are all thus found out and laid open.

In words.	Algebraically.
A merchant has an eſtate	x
Out of which the firſt year he ſpends 100 l.	$x - 100$
And augments the reſt by one third.	$x - 100 + \frac{x-100}{3}$, or $\frac{4x-400}{3}$
And the ſecond year he ſpends 100 l.	$\frac{4x-400}{3} - 100$, or $\frac{4x-700}{3}$
And augments the reſt by one third.	$\frac{4x-700}{3} + \frac{4x-700}{9}$, or $\frac{16x-2800}{9}$
And ſo the third year he ſpends 100 l.	$\frac{16x-2800}{9} - 100$, or $\frac{16x-3700}{9}$
And by the reſt gains likewiſe one third.	$\frac{16x-3700}{9} + \frac{16x-3700}{27}$ or $\frac{64x-14800}{27}$
And he becomes at length twice as rich as at firſt.	$\frac{64x-14800}{27} = 2x$.

Therefore the queſtion is brought to this equation, $\frac{64x-14800}{27} = 2x$, by reduction whereof you will find the value of x, viz. Multiply it into 27, and you have $64x - 14800 = 54x$; ſubtract $54x$, and there remains $10x - 14800 = 0$, or $10x = 14800$; and dividing by 10, you have $x = 1480$. So that the value of his eſtate at firſt was 1480 *l.*

It appears then, that to the ſolution of queſtions about numbers, or the relations of abſtract quantities, there is ſcarce any thing more required, but to tranſlate them out of the common into the algebraic language; i. e. into characters proper to expreſs our ideas of the relation of quantities. Indeed, it may ſometimes happen, that the language wherein the queſtion is ſtated, may ſeem unfit to be rendered into the algebraical; though by making a few alterations therein, and attending to the ſenſe, rather than the ſound of the words, the tranſlation becomes eaſy enough. The difficulty here reſults merely from the difference of idioms, which is as obſervable between moſt languages as between the common and ſymbolical. However, to render the ſolution of ſuch problems a little more eaſy and familiar, we ſhall add an example or two thereof.

1°. Given the ſum of two numbers a, and the difference of their ſquares b; to find the numbers themſelves: Suppoſe the leſſer x; the other will be $a - x$; and their ſquares x^2 and $a^2 - 2ax + x^2$; whoſe difference $a^2 - 2ax$ is called b; conſequently $a^2 - 2ax = b$: whence, by reduction, $aa - b = 2ax$; or $\frac{aa-b}{2a}$ $(= \frac{1}{2}a - \frac{b}{2a}) = x$.

E. gr. Suppoſe the ſum of the numbers, or a, to be 8, and the difference of their ſquares, or b, 16; then will $\frac{1}{2}a - \frac{b}{2a}$ $(= 4 - 1) = 3 = x$; and $a - x = 5$: therefore the numbers are 3 and 5.

2°. To find three quantities, x, y, and z, the ſum of each pair whereof is given: Suppoſe the ſum of the pair x and y be a; that of x and z, b; and that of y and z, c. To determine the three numbers required, x, y, and z; we have three equations, $x + y = a$, $x + z = b$, and $y + z = c$: now, to exterminate two of the unknown quantities, e. gr. y and x, take away x, both from the firſt and ſecond equations, and we ſhall have $y = a - x$, and $z = b - x$: which values being ſubſtituted for y and z in the third equation, there will ariſe $a - x + b - x = c$; and by reduction $x = \frac{a+b-c}{2}$. Having found x, the former equations, $y = a - x$, and $z = b - x$, will give y and z.

Thus, e. gr. If the ſum of the pair x and y be 9; of x and z, 10; and of y and z, 13; then, in the value x, y, and z, write 9 for a, 10 for b, and 13 for c; and you will have $a + b - c = 6$; and conſequently x $(= \frac{a+b-c}{2})$ $= 3$, y $(= a - x) = 6$, z $(= b - x) = 7$.

3°. The power or ſtrength of one agent being given; to determine how many ſuch agents will produce a given effect

effect a, in a given time b. Suppose the power of the agent such, as that it may produce the effect c in the time d; then, as the time d is to the time b, so is the effect c, which the agent can produce in the time d, to the effect it can produce in the time b, which accordingly will be $\frac{bc}{d}$. Then, as the effect of one agent $\frac{bc}{d}$ is to the joint effect of them all, a, so is that one agent to all the agents: consequently the number of agents will be $\frac{ad}{bc}$.

Thus, e. gr. If a clerk, or writer, in eight days time, transcribe 13 sheets; how many such clerks are required to transcribe 405 sheets in 9 days? Answer 24. For if 8 be substituted for d, 15 for c, 405 for a, and 9 for b, the number $\frac{ad}{bc}$ will become $\frac{405\times 8}{9\times 15}$; that is, $\frac{3240}{135}$, or 24.

4°. The power of several agents being given, to determine the time x, wherein they will jointly perform a given effect. Suppose the power of the agents A, B, C, such as that in the times e, f, g, they would produce the effects a, b, c, respectively; and these, in the time x, would produce effects $\frac{ax}{e}, \frac{bx}{f}, \frac{cx}{g}$: consequently $\frac{ax}{e}+\frac{bx}{f}+\frac{cx}{g}=d$, and by reduction x is equal to $\frac{d}{\frac{a}{e}+\frac{b}{f}+\frac{c}{g}}$.

Suppose, e. gr. that three workmen could finish a certain work in such and such times, viz. A once in three weeks, B thrice in eight weeks, and C five times in twelve weeks; and it is required in what time they will finish it together: here the powers of the agents A, B, C, are such as in the times 3, 8, and 12, respectively produce effects 1, 3, 5; and it is inquired in what time they will produce the effect, 1. For a, b, c, d, e, f, g, write 1, 3, 5, 1, 3, 8, 12; and there will come out $x=\frac{1}{\frac{1}{3}+\frac{3}{8}+\frac{5}{12}}$, or $\frac{8}{9}$ of a week, that is, 6 days, 5 $\frac{1}{3}$ hours, the time they will finish it in together.

5°. Given the specific gravities of a mixture, and of the several ingredients thereof; to find the proportion of the ingredients therein. Suppose e the specific gravity of the mixture A + B, a that of A, and b that of B: since the absolute gravity, or weight, is compounded of the bulk of the body, and its specific gravity, aA will be the weight of A; bB that of B; and eA + eB, the weight of the aggregate A + B; consequently aA + bB = eA + eB: and therefore aA − eA = eB − bB, or $\overline{e-b}\times$B. Hence A : B :: $e-b$: $a-e$.

Thus, e. gr. Suppose the specific gravity of gold to be as 19, that of silver as 10 $\frac{1}{2}$, and that of king Hiero's crown as 17; then will 10, 3 (:: $e-b$: $a-e$ :: A : B) :: the bulk of gold in the crown, to the bulk of silver: or 190 : 31 (:: 19×10. 16 $\frac{1}{2}\times 3$ :: $a\times\overline{e-b}$. $b\times\overline{a-e}$) :: the weight of the gold in the crown to the weight of the silver, and 221 : 31 :: the weight of the crown to the weight of silver.

To bring geometrical problems to equations.—Geometrical questions, or those relating to continued quantities, are sometimes also brought to equations after the same manner as arithmetical ones: so that the first rule to be here prescribed, is, to observe every thing directed for the solution of numerical problems.

Suppose, e. gr. it were required to cut a right line, as A B (plate LXIV. *fig.* 1.) in extreme and mean proportion in C; that is, so as that BE, the square of the greater part, shall be equal to the rectangle B D, contained under the whole line and the less part.

Here, supposing A B = a, and C B = x; then will AC = $a-x$; and $xx=aa-ax$. An equation, which by reduction, gives $x=\overline{\sqrt{\frac{5}{4}}-1}\times a$. But it is very rare that geometrical problems are thus brought to equation, as being generally found to depend on various complex positions, and relations of lines; so that here some farther artifice, and certain special rules, will be required to bring them to algebraic terms. Indeed, it is very difficult to prescribe any thing precise in such cases; every person's own genius should be the rule of their procedure.

Something, however, shall be said in the general, for the sake of those who are not versed in such operations, and principally from Sir I. Newton.

Observe then, that problems concerning lines related to each other in any definite manner, may be variously stated, by supposing such or such quæsita, or things sought, to be required from such or such data: yet still, with whatever data and quæsita the question is proposed, its solution will arise after the very same manner, without the least alteration of any circumstance, except in the imaginary species of lines, or in the names whereby the data are distinguished from the quæsita.

Suppose, e. gr. the question were about an isosceles triangle, BCD (*fig.* 2.) inscribed in a circle, whose sides, BC, BD, and base CD, were to be compared with the diameter of the circle AB. Here the question may be either proposed, of investigating of the diameter from the given sides and base; or investigating the base from the sides and diameter given: or, lastly, of finding the sides from the base and diameter given; and propose it under which form you will, it will be brought to an equation by the same algebraic series.

Thus, if the diameter be sought, put AB = x, CD = a, and BC or BD = b: then drawing AC, as the triangles ABC and CBE are similar; AB : BC :: BC : BE, or $x:b::b:$ BE; wherefore BE = $\frac{bb}{x}$, and CE = $\frac{1}{2}$ CD or $\frac{1}{2}a$. And, by reason the angle CEB is a right angle, $CE^q+BE^q=BC^q$; that is, $\frac{1}{4}aa+\frac{b^4}{xx}=bb$; which equation being reduced, gives the diameter required, x. Again, if the base be sought, put AB = c, CD = x, and BC or BD = b: then drawing AC, as the triangles ABC and CBE are similar, AB : BC :: BC : BE, or $c:b::b:$ BE; wherefore BE = $\frac{bb}{c}$; and CE = $\frac{1}{2}$ CD, or $\frac{1}{2}x$: and by reason the angle CEB is a right angle, $CE^2+BE^2=BC^2$; that is, $\frac{1}{4}aa+\frac{b^4}{xx}=bb$; which equation being reduced, gives the diameter required, x. Again, if the base be sought, put AB = c, CD = x, and BC or BD = b: then drawing AC, as the triangles ABC and CBE are similar, AB : BC :: BC : BE, or $c:x::x:$ BE; wherefore, BE = $\frac{xx}{c}$; and CE = $\frac{1}{2}$ CD, or $\frac{1}{2}x$; and the angle CEB being right, $\overline{CE}^2+\overline{BE}^2=\overline{BC}^2$; that is, $\frac{1}{4}xx+\frac{b^4}{cc}=bb$; an equation which, reduced, gives the base sought, x.

Lastly, if the side BC, or BD, were sought, put AB = c, CD = a, and BC or BD = x: then drawing AC, the triangles ABC and CBE being similar, we have AB : BC :: BC : BE, or $c:x::x:$ BE; wherefore, BE = $\frac{xx}{c}$; and CE = $\frac{1}{2}$ CD, or $\frac{1}{2}a$; and the angle CEB being right, $\overline{CE}^2+\overline{BE}^2=\overline{BC}^2$; that is, $\frac{1}{4}aa+\frac{x^4}{cc}=xx$; an equation which, by reduction, gives x required.

Thus is the calculus for arriving at the equation, as well as the equation itself, the same in all cases; except that the same lines are designed by different letters, according as they are data, or quæsita. Indeed, as the data or quæsita differ, there arises a difference in the reduction of the equation found, but there is no difference in the equation itself. So that we need make no difference between given and sought quantities; but are at liberty to state the question with such data and quæsita, as we think most favourable to the solution of the question.

To find the area of a triangle whose three sides are given in numbers.

First, the sum and difference of any two numbers multiplied together will give the difference of their squares, and *vice versa*; thus $\overline{a+y}\times\overline{a-y}=a^2-y^2$; and thus again $c^2-d^2=\overline{c+d}\times\overline{c-d}$.

Secondly, let the triangle proposed be A B C, (*fig.* 3.) whereof let A B = a, BC = b, and C A = c; and let $a+b+c$ (or the sum of all the sides) = 2s; then, if 2a be subtracted from both sides, you will have $-a+b+c=2s-2a$; and for a like reason $a-b+c=2s-2b$, and $a+b-c=2s-2c$.

Thirdly, draw the perpendicular AD, and the two right-

right-angled triangles ADB and ADC furniſh the two following equations, $AD^2 + DB^2 = AB^2$, and $AD^2 + DC^2 = AC^2$.

Fourthly, make $AD = x$, $BD = y$, and conſequently $CD = b - y$, and the two equations in the laſt ſtep according to this notation will ſtand thus:

$x^2 + y^2 \quad * \quad * = aa$,

and $x^2 + y^2 - 2by + b^2 = cc$. Subtract the latter equation from the former, and you will have

$* \; * + 2by - b^2 = a^2 - c^2$; whence $2by = a^2 + b^2 - c^2$.

Fifthly, ſince, by the laſt ſtep $2by = a^2 + b^2 - c^2$, we have $-2by = -a^2 - b^2 + c^2$, and $2ab - 2by$, or $2b \times \overline{a-y} = -a^2 + 2ab - b^2 + c^2$; make $a - b = d$, and you will have $a^2 - 2ab + b^2 = d^2$, and $-a^2 + 2ab - b^2 = -d^2$, and $-aa + 2ab - b^2 + c^2 = c^2 - d^2$; therefore, $2b \times \overline{a-y} = c^2 - d^2 = \overline{c-d} \times \overline{c+d} = \overline{c-a+b} \times \overline{c+a-b} = \overline{2s-2a} \times \overline{2s-2b} = 4 \times \overline{s-a} \times \overline{s-b}$; therefore from firſt to laſt, $2b \times \overline{a-y} = 4 \times \overline{s-a} \times \overline{s-b}$, and $\frac{2b}{4} \times \overline{a-y}$ or $\frac{b}{2} \times \overline{a-y} = \overline{s-a} \times \overline{s-b}$.

Sixthly, ſince, again, by the fourth ſtep, $2by = a^2 + b^2 - c^2$, we have $2ab + 2by$, or $2b \times \overline{a+y} = a^2 - 2ab + b^2 - c^2$; make $a + b = d$, and you will have $a^2 + 2ab + b^2 = d^2$, and $a^2 + 2ab + b^2 - c^2 = d^2 - c^2 = \overline{d-c} \times \overline{d+c} = \overline{a+b-c} \times \overline{a+b+c} = \overline{2s-2c} \times 2s = 4 \times \overline{s-c} \times s$; therefore, from firſt to laſt we have $2b \times \overline{a+y} = 4 \times \overline{s-c} \times s$, and $\frac{b}{2} \times \overline{a+y} = \overline{s-c} \times s$.

Seventhly, multiply the equations found in the two laſt ſteps together, viz. $\frac{b}{2} \times \overline{a-y} = \overline{s-a} \times \overline{s-b}$, and $\frac{b}{2} \times \overline{a+y} = \overline{s-c} \times s$, and you will have (by the firſt) $\frac{b^2}{4} \times \overline{a^2 - y^2} = \overline{s-a} \times \overline{s-b} \times \overline{s-b} \times \overline{s-c} \times s$.

Eighthly, but by the fourth ſtep $a^2 = x^2 + y^2$, and $a^2 - y^2 = x^2$; therefore $\frac{b^2 x^2}{4} = \overline{s-a} \times \overline{s-b} \times \overline{s-c} \times s$.

Ninthly, extract the ſquare root of both ſides, and you will have $\frac{bx}{2}$, or $AD \times \frac{1}{2} BC$, or the area ſought, equal to the ſquare root of the product $\overline{s-a} \times \overline{s-b} \times \overline{s-c} \times s$. In words thus.

From half the ſum of the ſides ſubtract the three ſides ſeverally, and mark down the remainders; then, if theſe three remainders and that half ſum be multiplied together by a continual multiplication, the ſquare root of the product will be the area ſought.

Note, if the perpendicular falls without the triangle, the inveſtigation of this theorem will ſtill be the ſame, only now the ſign of y will be changed. For the nature, &c. of quadratic, cubic, &c. equations; ſee QUADRATIC, CUBIC, &c.

Conſtruction of EQUATIONS. See GEOMETRICAL *Conſtruction of Equations*.

EQUATION *of Time*, in aſtronomy, the reducing of the apparent, unequal time, or motion of the heavenly bodies to equable or mean time, or motion.

Since the diurnal motion of the earth about its axis is equable, every revolution will be performed in the ſame time, and therefore all the ſidereal days, and the hours of thoſe days, will be equal. And on the other hand, the ſolar days are all unequal, and that on two accounts; to wit, becauſe of the ecliptic figure of the earth's orbit, and becauſe of the obliquity of the ecliptic to the equator.

This will appear as follows: Let S (plate LXIV. *fig.* 2.) be the ſun, A B a part of the ecliptic, A the center of the earth, and M D a meridian, whoſe plane paſſes through the ſun. Now, in the time of one revolution about its axis, let the earth be carried about the ſun from A to B, and then the meridian will be in the poſition *m d*, parallel to the former M D. But it is plain, the meridian *m d* is not yet directed to the ſun, nor will, till by its angular motion it has attained the ſituation *e f*, deſcribing the angle $e B m = B S A$; whence it appears, that all the ſolar days are longer than the time of one revolution or ſidereal day.

If the earth revolved in the plane of the equator, and in a circle about the ſun, then would the angle A S B, and conſequently the angle $e B m$, be always of the ſame quantity; and therefore the time of deſcribing the ſaid angle $e B m$ would always be equal; and ſo all the ſolar days would be equal among themſelves. But neither of theſe two caſes have place in nature. For by the earth's theory, founded on the niceſt obſervations, the orbit is an ellipſis; and, therefore, her annual motion cannot be equable, or the angle A S B, deſcribed in the ſame ſpace of time, will not be equal; for in the aphelion the velocity of the earth will be leſs than in the perihelion; therefore, alſo, the arch A B will be leſs; and, conſequently, the ſimilar arch *e m*, and, therefore, alſo the time of deſcribing it: whence it appears, that the part of time to be added to the ſidereal day, to complete the ſolar day, is always variable.

The other, and the moſt conſiderable part of the equation of time, is that which ariſes from the plane of the earth's orbit or ecliptic being inclined to that of the equator or plane of the diurnal motion: to explain which, let ♈ ♋ ♎ (plate LXIV. *fig.* 3.) be a ſemicircle of the ecliptic, and ♈ H ♎ of the equinoctial, S the center of the ſun, and A that of the earth in the third quarter of the ecliptic, *b f* the meridian paſſing through the true ſun S, and its apparent place as I, in the firſt quarter of the ecliptic ♈ ♋.

Suppoſe now the motion of the earth in every reſpect equable; and firſt, that it ſet out from ♎, and proceeded in the equator in a given time to D, the ſun would apparently deſcribe in the ſame time the arch of the equator ♈ I. Again, ſuppoſe it ſet out from the ſame point, ♎, and ſpent the ſame time with the ſame equable velocity in the ecliptic, it would arrive at the point A; ſo that the arch ♎ A = ♎ D, and ♈ I = ♈ C; then it is evident, as the earth revolves about its axis from weſt to eaſt, the meridian of any place will firſt arrive at the ſun I in the ecliptic, and afterwards at the ſun C in the equinoctial; that is, the time of noon by the ſun in the ecliptic will be ſooner than that of noon by noon, which would happen by the ſun in the equinoctial; and that by the quantity of the arch *b* D turned into time.

Now the arch *b* D = B C is the difference of the ſun's longitude ♈ I, or ♈ C, and his right aſcenſion ♈ B; draw *g e* parallel to D C, and the angle *e* A *f* will be equal to the angle D S *h*, and the arch *e f* ſimilar to the arch D *h*; therefore, the time in which the meridian *b f* revolves into the ſituation *e g*, is that which is to be added to the ecliptic noon, to equate it with the time of the equinoctial noon, in the firſt and third quarters of the ecliptic. In the ſecond and fourth quarters, the ſaid equation is to be ſubtracted, as would eaſily appear by making the ſame conſtruction there.

Now, becauſe in different parts of the quadrant this arch D *b* or B C is of a different length, the equation of time will be a variable quantity; and, therefore, ſince the motion and time meaſured by the ſun in the equinoctial is always equal, there being nothing to make it otherwiſe, it follows, that the times, that is, the days, meaſured by the ſun in the ecliptic muſt be always unequal; or, in other words, the ſolar days are ſometimes ſhorter, ſometimes longer, than the equal time meaſured out in the equinoctial.

The true motion of the earth precedes the mean in the firſt ſemicircle of anomaly, and is preceded by the mean in the ſecond: therefore, while the earth is going from the aphelion to the perihelion, or while the ſun apparently moves from the apogæum to the perigæum, the apparent time will be before the mean; and in the other ſemi-circle of anomaly it will be after it. The difference of theſe motions, converted into time, is the equation of time in this reſpect, and it is to be ſubtracted from the apparent time to gain the mean, or added to the mean to gain the apparent, in the firſt ſemicircle of anomaly, and *vice verſa* in the latter.

Now both theſe parts of the equation of time are calculated by aſtronomers for every degree of anomaly, and for every degree of the ſun's longitude in the ecliptic, and diſpoſed in two ſeveral tables, with directions for adding and ſubtracting, as the caſe requires; ſo that at all

all times, the true or equal time may be had. And from thence it appears, that the apparent time, or that ſhewn by the ſun, namely, by a ſun-dial, is but four days in the whole year the ſame with the mean or equal time ſhewn by a good clock or watch, to wit, about the fifteenth of April, the ſixteenth of June, the thirty-firſt of Auguſt, and the twenty-fourth of December. Alſo about the firſt of November, the equation is greateſt of all in the year, being then about 16′ 13″; clocks being then ſo much ſlower than ſun-dials.

Mr. FLAMSTEAD's TABLE of the EQUATION of natural Days, with the Regulation of a Movement by the ſame.

Equal time ſlower to the next aſteriks.

Equal time faſter to the next aſteriks.

Equal time faſter.

EQUATOR, in geography, a great circle of the terreſtrial globe, equidiſtant from its poles, and dividing it into two equal hemiſpheres; one north, and the other ſouth. See the article GLOBE.

It paſſes through the eaſt and weſt points of the horizon, and at the meridian is raiſed as much above the horizon as is the complement of the latitude of the place. From this circle, the latitude of places, whether north or ſouth, begin to be reckoned, in degrees of the meridian. See LATITUDE and MERIDIAN.

All people living on this circle, called by geographers and navigators the line, have their days and nights conſtantly equal.

It is in degrees of the equator that the longitude of places are reckoned; and as the natural day is meaſured by one revolution of the equator, it follows that one hour anſwers to $\frac{360}{24} = 15$ degrees: hence one degree of the equator will contain four minutes of time; fifteen minutes of a degree will make a minute of an hour; and, conſequently, four ſeconds anſwer to one minute of a degree.

EQUERRY, in the Britiſh cuſtoms, an officer of ſtate, under the maſter of the horſe.

There are five equerries, who ride abroad with his majeſty; for which purpoſe they give their attendance monthly, one at a time, and are allowed a table.

As to the equerries of the crown ſtable, they have this diſtinct appellation, as being employed in mounting, managing, and breaking the ſaddle-horſes for his majeſty's uſe, and holding his ſtirrup.

EQUESTRIAN STATUE ſignifies the ſtatue of a perſon mounted on horſeback.

EQUESTRIAN ORDER, among the Romans, ſignified their knights, or equites; as alſo their troopers, or horſemen in the field; the firſt of which orders ſtood in contradiſtinction to the ſenators, as the laſt did to the foot, military, or infantry: each of theſe diſtinctions was introduced into the ſtate by Romulus.

EQUIANGULAR, in geometry, an epithet given to figures whoſe angles are all equal: ſuch are a ſquare, an equilateral triangle, &c.

EQUICRURAL, in geometry, the ſame with iſoſceles. See the article ISOSCELES.

EQUICULUS, or EQUULEUS. See the article EQUULEUS.

EQUIDIFFERENT NUMBERS, in arithmetic, are of two kinds, 1. Continually equidifferent is when, in a ſeries of three numbers, there is the ſame difference between the firſt and ſecond, as there is between the ſecond and third; as 3, 6, 9. And, 2. Diſcretely equidifferent, is when in a ſeries of four numbers or quantities, there is the ſame difference between the firſt and ſecond, as there is between the third and fourth: ſuch are 3, 6, 7, 10.

EQUIDISTANT, an appellation given to things placed at equal diſtance from ſome fixed point, or place, to which they are referred.

EQUILATERAL, in general, ſomething that hath equal ſides, as an equilateral angle.

EQUILATERAL HYPERBOLA, one whoſe tranſverſe diameter is equal to its parameter; and ſo all the other diameters, equal to their parameters: in ſuch an hyperbola, the aſymptotes always cut one another at right angles in the center. Its moſt ſimple equation, with regard to the tranſverſe axis, is $y^2 = x^2 - a^2$; and, with regard to the conjugate, $y^2 = x^2 + a^2$, when a is the ſemitranſverſe, or ſemi-conjugate. The length of the curve cannot be found by means of the quadrature of any ſpace, of which a conic ſection is any part of the perimeter. See the article HYPERBOLA.

EQUI-

EQUILIBRIUM, in mechanics, is when the two ends of a lever or ballance hang ſo exactly even and level, that neither doth aſcend or deſcend, but keep in a poſition parallel to the horizon; which is occaſioned by their being both charged with an equal weight.

EQUIMULTIPLES, in arithmetic and geometry, are numbers or quantities multiplied by one and the ſame number or quantity. Hence, equimultiples are always in the ſame ratio to each other, as the ſimple quantities before multiplication: thus, if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other as 6 to 8.

EQUINOCTIAL, in aſtronomy, a great circle of the celeſtial globe, whoſe poles are the poles of the world.

It is ſo called, becauſe whenever the ſun comes to this circle, the days and nights are equal all over the globe; being the ſame with that which the ſun ſeems to deſcribe at the time of the two equinoxes of ſpring and autumn. See the article EQUINOX.

All ſtars, directly under this circle, have no declination, and always riſe due eaſt, and ſet full weſt. The hour circles are drawn at right angles to it, paſſing thro' every fifteenth degree; and the parallels to it are called parallels of declination. See the articles DECLINATION and CIRCLE.

EQUINOCTIAL	COLURE,	See	COLURE.
	DIAL,		DIAL.
	HOUR,		HOUR.
	LINE,		LINE.
	OCCIDENT,		OCCIDENT.
	ORIENT,		ORIENT.
	POINT, &c.		POINT, &c.

EQUINOX, the time when the ſun enters either of the equinoctial points, where the ecliptic interſects the equinoctial. See the preceding article.

It is ſo called, becauſe when the ſun is in theſe points, the days and nights are of an equal length all the world over. As the ſun is in one of them, in the ſpring, viz. March 20th, it is called the vernal equinox; and in the other, in autumn, viz. September 23d, it is called the autumnal equinox.

Preceſſion of the EQUINOXES. See the article PRECESSION.

EQUIPOLLENCE, in logic, is when there is an equivalence, or agreement, either as to the nature of things, or as to the grammatical ſenſe of any two propoſitions; that is, when two propoſitions ſignify one and the ſame thing, though they expreſs it after different manners.

EQUISETUM, horſetail, in botany, a genus of plants, and order of filices, or ferns; the fructifications of which are diſpoſed on an oblong ſpike, and are of an orbicular figure, dividing in various angles from the baſe. The plant itſelf conſiſts of jointed ſtalks, in ſome ſimple, in others branched; producing ſetæ, or ſmaller diviſions, of the ſame ſtructure with the larger ones.

EQUITY, in a general ſenſe, the virtue of treating all other men according to common reaſon and juſtice, or as we would be gladly treated ourſelves, when we underſtand aright what is our due. See the article JUSTICE.

EQUITY *of Redemption*, in our law, is applied to mortgages, as where money being due on a mortgage, the mortgagee is deſirous to bar the mortgager's equity of redemption, that is, his right to redeem the mortgage. In this caſe the mortgagee may oblige the mortgager, either to pay the money, or to be foreclоſed of his equity of redemption. The practice is to exhibit a bill, to which anſwer being put in, and a decree obtained, a maſter of that court certifies what is due for principal, intereſt, and coſts, which is to be paid within the time limited by the decree; and thereupon, the eſtate mortgaged is to be reconveyed to the mortgager, otherwiſe, for default of payment, the mortgager is decreed to be foreclоſed from all equity of redemption, and abſolutely to convey the mortgaged premiſes to the mortgagee. See MORTGAGE.

EQUITY alſo frequently ſignifies the court of chancery, where controverſies are determined according to the exact rules of equity and conſcience, by mitigating the rigour of the common law; though even by the common and ſtatute law there is alſo an equity. See the article CHANCERY.

EQUIVALENT, an appellation given to things which agree in nature, or other circumſtances, as force, nature, &c.

EQUIVOCAL TERMS, or *Words*, among logicians, are thoſe which have a doubtful, or double meaning.

According to Mr. Locke, the doubtfulneſs and uncertainty of words has its cauſe more in the ideas themſelves, than in any incapacity of the words to ſignify them; and might be avoided, would people always uſe the ſame term to denote the ſame idea, or collection of ideas: but, adds that great man, it is hard to find a diſcourſe on any ſubject where this is the caſe; a practice which can only be imputed to folly, or great diſhoneſty; ſince a man, in making up his accompts, might, with as much fairneſs, uſe the numerical character ſometimes for one, ſometimes for another collection of unities.

EQUIVOCAL ACTION is, where the effect is of a different kind from the cauſe producing it.

EQUIVOCAL CAUSE. See CAUSE.

EQUIVOCAL GENERATION, the production of animals, without the intercourſe between the ſexes, by the influence of the ſun or ſtars, &c.

The equivocal generation of plants, is their production without ſeed, in the ordinary courſe of nature. See the article GENERATION.

This kind of generation is now quite exploded by the learned.

EQUIVOCATION, in ethics, the crime of wilfully uſing equivocal terms.

EQUULEUS, or ECUULEUS, in antiquity, a kind of rack uſed for extorting a confeſſion, at firſt chiefly practiſed on ſlaves, but afterwards made uſe of againſt the chriſtians.

The equuleus was made of wood, having holes at certain diſtances, with a ſcrew, by which the criminal was ſtretched to the third, ſometimes to the fourth, or fifth holes, his arms and legs being faſtened on the equuleus with cords; and thus was hoiſted aloft, and extended in ſuch a manner, that all his bones were diſlocated. In this ſtate red-hot plates were applied to his body, and he was goaded in the ſides with an inſtrument called ungula.

EQUULEUS, in aſtronomy, a conſtellation of the northern hemiſphere, whoſe ſtars, according to Ptolemy, and Tycho's catalogues, are four, but in Mr. Flamſtead's ten.

EQUUS, the HORSE, in zoology. See HORSE.

EQUUS MARINUS, in ichthyology, the ſame with the morſe. See MORSE.

ERASED, in heraldry, the ſame with arrache. See the article ARRACHE.

ERECT FLOWERS, ſuch as grow upright without hanging or reclining the head. See the article FLOWER.

ERECT DIAL. See the article DIAL.

ERECT VISION. See the article VISION.

ERECTOR CLITORIS, in anatomy, one of the two muſcles of the clitoris that ſerve for its erection.

The erectores of the clitoris ariſe from the oſſa iſchii, and are inſerted into the corpora cavernoſa.

ERECTOR PENIS, one of the two muſcles of the penis, that ſerve for its erection.

Theſe ariſe on each ſide, from the oſſa iſchii between the tubercle of this bone and the beginning of the corpus cavernoſum, and each of them is inſerted into the corpus cavernoſum of its own ſide. Theſe muſcles, when they act together, preſs the veins of the back of the penis againſt the oſſa pubis, by which they prevent the reflux of blood from the penis; and conſequently, when at the ſame time the blood flows impetuouſly into the parts by the arteries, and cannot get back this way, the penis becomes erected.

ERIGERON, ſweet fleabane, in botany, a genus of plants, the compound flower of which is radiated; the partial hermaphrodite one infundibuliform; and the female flower is ligulated, linear, and ſubulated: the fruit has no pericarpium, the cup is connivent: the ſeeds of the hermaphrodite flower are oblong, ſmall, and crowned with long down.

This plant is a diuretic, and promotes the menſes: the ſmell of it drives away fleas, and kills lice and other like vermin.

ERMIN, *Ermineum*, in zoology, a creature whoſe ſkin is the ermin, ſo much eſteemed as a fine fur.

This creature is properly a ſpecies of weaſel, and is called by Mr. Ray, and other authors, muſtela candida, the white weaſel. It is in all reſpects like the common weaſel, and is all over of a pure ſnow-white, except the tip of the tail, which is of as beautiful a black; and it has a little yellowiſh grey about the eyes, and a mark, or ſpot, of the ſame colour, on the head, another on the ſhoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the ſeaſon of the year. It is frequent about rivers, and in meadows, in thoſe countries which produce it, and feeds on moles, mice, and other ſmall animals.

ERMIN, in heraldry, is always argent and ſable, that is, a white field, or fur, with black ſpots. Theſe ſpots are not of any determinate number, but may be more or leſs, at the pleaſure of the painter, as the ſkins are thought not to be naturally ſo ſpotted; but ſerving for lining the garments of great perſons, the furriers were wont, in order to add to their beauty, to ſow bits of the black tails of the creatures that produced them, upon the white of their skin, to render them the more conſpicuous, which alteration was introduced into armory. (See plate LXII. *fig.* 3.)

ERMIN, or EARS OF CORN, an order of knights in France, inſtituted by Francis the laſt of that name, duke of Brittany.

ERMINE', or croſs ermine, is one compoſed of four ermin ſpots, placed as repreſented in *fig.* 4.

It is to be obſerved, that the colours in theſe arms, are not to be expreſſed, becauſe neither this croſs, nor theſe arms, can be of any other colour but white and black.

ERMINES are, by ſome Engliſh writers, held to be the reverſe of ermine, that is, white ſpots on a black field, and yet the French uſe no ſuch word, but call this black powdered with white *contre ermin*, which is very proper, as it denotes the reverſe of ermin. See the article ERMIN.

ERMINITES ſhould ſignify little ermines, but it is otherwiſe; for it expreſſes a white field powdered with black, only that every ſuch ſpot hath a little red hair on each.

Erminites alſo ſignify a yellow field powdered with black, which the French expreſs much better by *or ſemée d'ermine de ſable*.

EROSION, among phyſicians, denotes much the ſame with corroſion, only in a ſtronger degree. See the articles CORROSION and CORROSIVES.

ERRATA, a liſt of the errors or faults in the impreſſion of a book, generally placed at the beginning thereof.

ERRATIC, in general, ſomething that wanders, or is not regular: hence it is, the planets are called erratic ſtars; as thoſe fevers, which obſerve no regular periods, are denominated erratic fevers.

ERRHINES, ἐρρῖνα, in pharmacy, medicines which, when ſnuffed up the noſe, promote a diſcharge of mucus from that part.

The excretion of the mucous lymph is excellently promoted by errhines and ſternutatories, the former of which ſtimulate the pituitary coats but gently, whereas the latter more forcibly ſtimulate them to an extretory motion. See the article STERNUTATORY.

ERROUR, ERROR, in philoſophy, a miſtake of our judgment, giving aſſent to that which is not true.

Mr. Locke reduces the cauſes of error to theſe four; firſt, want of proofs; ſecondly, want of ability to uſe them; and, thirdly, want of will to uſe them; and fourthly, wrong meaſures of probability.

ERUCA, the white rocket, in botany, a ſpecies of braſſica. See the article BRASSICA.

ERUCA, wild rocket, in botany, a genus of plants, whoſe characters are:

The pod is full of roundiſh ſeeds, and the plant has a particular taſte, and a particular fœtid ſmell above all others.

This rocket has a long white root, with many fibres at the bottom; from which ariſe a great many ſtriated ſtalks a foot or two high, full of narrow, long, and deeply laciniated leaves. The flowers are pretty large and yellow, of four leaves a-piece, which are ſucceeded by long, narrow, angular pods, full of ſmall, hot, bitteriſh ſeed: The whole plant has an ungrateful, fœtid ſmell. It grows frequently upon old walls, in great plenty, flowering great part of the ſummer.

This plant is of a ſtate altogether acrid and burning, mixed at laſt with a little bitterneſs; it gives a pretty deep tincture of red to the blue paper, and its ſmell reſembles that of fœtid oils rectified over quicklime; which makes us believe, that it contains a ſalt very acrid, which in ſome meaſure reſembles the ſal ammoniac, mixed with a great deal of fœtid oil and earth.

Thus it is no wonder, that the plant of which we are ſpeaking, ſhould be aperitive, inciſive, and diuretic. Matthiolus affirms, that, being boiled with a little ſugar, it is good for the cough in children, which is generally occaſioned by glutinous matters, irritated in the bronchia and veſicles of the lungs.

ERUCTATIONS, in medicine, are the effects of flatulent foods, and the crudities thence ariſing. See FLATULENCY.

ERUDITION, *eruditio*, denotes an extenſive acquaintance with books, eſpecially ſuch as treat of the Belles Lettres.

ERUPTION, in medicine, a ſudden and copious excretion of humours, as pus or blood: it ſignifies alſo the ſame with exanthema, any breaking out, as the puſtules of the plague, ſmall-pox, meaſles, &c.

ERYNGIUM, ERINGO, in botany, a genus of plants, the general corolla of which is uniform and roundiſh; the partial one conſiſts of five oblong petals, knotted together by a longitudinal line. The fruit is of an oval figure, and diviſible in two parts: the ſeeds are oblong and roundiſh.

The root of eryngium is attenuant and deobſtruent, and is therefore eſteemed a good hepatic, uterine, and nephritic. Its whole virtue conſiſts in the external or cortical part.

ERYSIMUM, hedge muſtard, in botany, a genus of plants, the corolla whereof conſiſts of four oblong, cruciform petals, with a very obtuſe point: the fruit is a long, linear, four-cornered pod, conſiſting of two valves, and divided into two cells: the ſeeds are numerous, ſmall, and roundiſh.

This plant is recommended in paralytic and epileptic caſes; it expels poiſon, deſtroys worms, ſtrengthens the ſtomach, and cures ulcers of the mouth.

ERYSIPELAS, otherwiſe called St. Anthony's fire, is that ſpecies of inflammation, which ariſing in the ſkin, and its ſubjacent fat, ſometimes ſpreads itſelf very far, and is accompanied with redneſs, heat, and pain. The part affected, when preſſed with the finger, becomes remarkably white; but, ſoon after its removal, reſumes its former redneſs.

The word is Greek, ἐρυσιπελας, and derived from ἐρυθρὸς, red, and πελὸς, livid; becauſe of the colours it induces on the affected part.

Though inflammations of this kind generally ariſe on the arms and legs, yet they ſometimes happen on the neck, the head, the ſhoulders, noſe, and other parts. Upon the firſt approach of this diſorder, the patient is almoſt always ſeized with a ſhivering and coldneſs, which are ſoon ſucceeded by a degree of heat, equal to that perceived in burning fevers: for this reaſon, it is often called *ignis ſacer*, both by ancient and modern authors.

Great attention is to be given to that fever which is accompanied with an eryſipelas; for in this, beſides the pain, thirſt, and reſtleſſneſs, which the patient ſuffers, the puſtules on various parts of the body ſometimes run into gangrenes.

Wherefore, the firſt thing to be done is to draw blood pretty plentifully; and then to purge once or more with gentle cathartics, as infuſion of ſena with manna, for ſuch only are proper in fevers. And indeed there is no acute fever that bears repeated purging better than this, eſpecially when the inflammatory tumour has ſeized the head: for the humour ſpreads very faſt, and ſoon gains the neighbouring parts.

But it is dangerous to apply hot fomentations, in order

to diſcuſs the morbific matter; and much more ſo to repel it with cooling ointments or liniments: but if the ſkin in any part be gangrened, that part is to be fomented with a decoction of bitter herbs, mixed with camphorated ſpirit of wine; and afterward a cataplaſm of oatmeal boiled in ſtrong beer is to be laid on warm, and to be renewed as often as is found neceſſary.

And to give this caution once for all, not only in acute diſeaſes, but in ſeveral chronical, which are attended with puſtules that ſuppurate, it is ſafer and better, unleſs the ſkin is the ſole ſeat of the diſorder, to encourage the eruption by gentle means, or at leaſt to ſuffer it to come forth for ſome time, that is, as far as the patient can bear the uneaſineſs, than either to repel or purge off the humour by other outlets: for there is in every vicious humour ſomewhat peculiar to itſelf; and, as they generally come forth by way of criſis, how much ſoever they may be diminiſhed, yet they are rarely evacuated out of the body, with relief to the ſick, by any other paſſages than thoſe pointed out by nature. *Mead's Monita & Præcepta.*

ERYTHROIDES, in anatomy, the firſt of the proper tunics or coats which cover the teſticles. See TESTICLE.

ERYTHRONIUM, dog's tooth-violet, in botany, a genus of plants, the flower of which conſiſts of ſix oblong and lanceolated petals; and the fruit is a ſubgloboſe capſule, with three cells, in which are contained numerous ovato-acuminated ſeeds.

The root of this plant is recommended againſt the cholic, epilepſy, and worms: it is alſo reckoned a provocative to venery.

ESCALADE, or SCALADE, in the art of war. See the article SCALADE.

ESCAPE, in law, a violent or privy evaſion out of ſome lawful reſtraint, without being delivered by due courſe of law.

ESCAPE-WARRANT, a proceſs which iſſues out againſt a perſon committed in the King's-bench or Fleet-priſons, that, without being duly diſcharged, takes upon him to go at large.

Upon this warrant, which is obtained on oath, a perſon may be apprehended on a Sunday.

ESCHALOT, *Cepa Aſcalonica*, a ſpecies of onion cultivated in gardens for its uſe in cookery. See ONION.

ESCHEAT, in law, ſignifies any lands or tenements that caſually fall to a lord within his manor, by way of forfeiture, or by the death of his tenant, without any heirs general or ſpecial.

ESCHRAKITES, in matters of religion, a ſect of Mahometans, who believe that man's ſovereign good conſiſts in the contemplation of God. They avoid all manner of vice, and appear always in good humour, deſpiſing the ſenſual paradiſe of Mahomet. The moſt able preachers, in the royal moſques, are of this ſect.

ESCLATTE, in heraldry, ſignifies a thing forcibly broken, or rather a ſhield that has been broken and ſhattered with the ſtroke of a battle-ax.

ESCORT, in the art of war, the ſame with convoy. See the article CONVOY.

ESCULENT, an appellation given to ſuch plants, or the roots of them, as may be eaten: ſuch are beets, carrots, artichokes, leeks, onions, parſnips, potatoes, radiſhes, ſcorzonera, &c.

ESCULUS, the horſe-cheſnut, a genus of trees, belonging to the heptandria-monogynia claſs of plants: its flower conſiſts of five roundiſh petals; and the fruit is a roundiſh, echinated, and coriaceous capſule, with only one cell, in which are contained two roundiſh ſeeds, tho' ſometimes only one.

ESCUTCHEON, or SCUTCHEON, in heraldry, is derived from the French *eſcuſſon*, and that from the Latin *ſcutum*, and ſignifies the ſhield whereon coats of arms are repreſented.

Moſt nations, of the remoteſt antiquity, were wont to have their ſhields diſtinguiſhed by certain marks painted on them; and to have ſuch on their ſhields was a token of honour, none being permitted to have them till they had performed ſome honourable action.

The eſcutcheon, as uſed at preſent, is ſquare, only rounded off at the bottom.

As to the bearings on ſhields, they might at firſt be arbitrary, according to the fancy of the bearer; but, in proceſs of time, they came to be the gift of kings and generals, as the reward of honourable actions.

ESCUTCHEON *of Pretence*, that on which a man carries his wife's coat of arms, being an heireſs, and having iſſue by her. It is placed over the coat of the huſband, who thereby ſhows forth his pretenſions to her lands.

ESDRAS, the name of two apocryphal books, uſually bound up with the Scriptures. They were always excluded the Jewiſh canon, and are too abſurd to be admitted as canonical by the papiſts themſelves. The firſt book is chiefly hiſtorical, giving an account of the return of the Jews from the Babyloniſh captivity, and the building of the ſecond temple; the ſecond is written in the prophetical way, pretending to viſions and revelations, but ſuch as are extremely ridiculous.

ESLIRASS, in law, perſons particularly appointed or choſen to impannel juries.

ESNECY, in law, a private prerogative allowed to the eldeſt coparcener, where an eſtate is deſcended to daughters for want of an heir male, to chooſe firſt, after the eſtate of inheritance is divided.

ESPALIERS, in gardening, are rows of trees planted about a whole garden or plantation, or in hedges, ſo as to incloſe quarters or ſeparate parts of a garden; and are trained up regularly to a lattice of wood-work in a cloſe hedge, for the defence of tender plants againſt the injuries of wind and weather. They are of admirable uſe and beauty in a kitchen garden, ſerving not only to ſhelter the tender plants, but ſcreen them from the ſight of perſons in the walks.

The trees chiefly planted for eſpaliers, are apples, pears, and ſome plums; but the two former are moſtly uſed: ſome plant eſpaliers of apples grafted upon paradiſe ſtocks; but theſe, being of a ſhort duration, are not ſo proper for this purpoſe; therefore I ſhould rather adviſe the having them upon crab ſtocks, or (if in ſmall gardens, where the trees cannot be allowed to grow ſo high) upon what the gardeners call the Dutch ſtock; which will cauſe them to bear much ſooner, and prevent their growing too luxuriant.

In chuſing the trees for an eſpalier, endeavour, as near as poſſible, to plant the ſeveral ſorts which are nearly of the ſame growth in one line, that the eſpalier may be the more regular, and of an equal height, which greatly adds to their beauty; for if you plant trees which ſhoot very unequally in the ſame line, it will be impoſſible to make the eſpalier regular: beſides, the diſtance the trees are to be planted muſt be directed hereby; for ſome trees, viz. thoſe of a larger growth, ſhould be planted twenty-five or thirty feet aſunder; whereas thoſe of ſmaller growth need not be above ſixteen or eighteen feet diſtance from each other.

The width of the walks between theſe eſpaliers ſhould (in a large garden) be fourteen or ſixteen feet at leaſt; and, if they are deſigned to be carried up pretty high, the diſtance ſhould be greater, that each ſide may receive the advantage of the ſun and air, which is abſolutely neceſſary, if you would have the fruit well taſted: and if your ground is ſo ſituated, that you are at full liberty which way to make the eſpaliers, I would adviſe the placing the lines from the eaſt a little inclining to the ſouth, and toward the weſt a little inclining to the north, that the ſun may ſhine between the rows in the morning and evening, when it is low; for in the middle of the day, when the ſun is advanced far above the horizon, it will ſhine over the tops of the eſpaliers, and reach the ſurface of the earth about their roots; which is a matter of more conſequence than many people are aware of.

The ſorts of apples proper for eſpaliers are the golden pippin, nonpareil, rennette griſe, aromatic pippin, Holland pippin, French pippin, Wheeler's ruſſet, Pile's ruſſet, with ſeveral others.

The ſorts of pears proper for an eſpalier are ſummer and autumn fruits; for ſome of the winter pears ſeldom ſucceed well in an eſpalier. Theſe trees, if deſigned for a ſtrong moiſt ſoil, ſhould be upon quince ſtocks; but if for a dry ſoil, upon free ſtocks. Their diſtance of planting muſt alſo be regulated by the growth of the trees, which are more unequal in pears than apples, and ſhould therefore be more carefully examined before they are planted

planted. As for thoſe pears upon free ſtocks, the diſtance ſhould never be leſs than twenty-five feet for moderate-growing trees; but, for vigorous ſhooters, the ſpace of thirty or five and thirty feet is little enough, eſpecially if the ſoil be ſtrong, in which caſe they ſhould be planted at a greater diſtance. The particular ſorts of pears I would recommend for an eſpalier, are the jargonelle, blanguette, poir ſans peau, ſummer boncretien, Hambden's burgamot, poir du prince, autumn burgamot, l'ambrette, gros rouſſelet, chaumontelle, beurre du roy, le marquis, creſſane, with many others of leſs note, always remembering that thoſe pears which are of the melting kind, will do better in eſpaliers than the breaking pears, which ſeldom ripen well on eſpaliers: you ſhould alſo be careful of the ſtocks theſe are grafted on; for if the breaking pears are grafted on quince ſtocks, the fruit will be ſtony.

I ſhall now give directions for making the eſpalier, to which the trees are to be trained: but this I would not have done until the third year after the trees are planted; for, while they are young, it will be ſufficient to drive a few ſhort ſtakes into the ground on each ſide of the trees, to which the branches ſhould be faſtened in an horizontal poſition, as they are produced; which ſtakes may be placed nearer, or at a farther diſtance, according as the ſhoots produced may require, and will be ſufficient for the three firſt years; for ſhould you frame the eſpalier the firſt year the trees are planted, the poles would rot before the eſpalier is covered. The cheapeſt method to make theſe eſpaliers is with aſh poles, of which you ſhould have two ſorts; one of the largeſt ſize, which contains thirteen poles in a bundle, and the other ſize thoſe of half a hundred; the firſt or largeſt ſize poles ſhould be cut about ſeven feet and an half long; theſe are intended for upright ſtakes, and muſt be ſharpened at the largeſt end, that they may, with more eaſe, be driven into the ground; theſe ſhould be placed at a foot diſtance from each other in a direct line, and of an equal height, about ſix feet above ground; then you ſhould nail a row of ſtraight ſlender poles along upon the tops of the upright ſtakes, which will keep them exactly even, and continue to croſs the ſtakes with the ſmaller poles, and the tops which were cut off from the larger ones, at about nine inches diſtance, row from row, from the top to the bottom of the ſtakes. Theſe rows of poles ſhould be faſtened with wire, and the largeſt end of the poles ſhould be nailed to the upright ſtakes, which will ſecure the eſpalier almoſt as long as the poles will endure; whereas, if your faſtening is not ſtrong, the poles will be continually diſplaced with every ſtrong wind. When your eſpalier is thus framed, you muſt faſten the branches of the trees thereto, either with ſmall oſier twigs, or ſome ſuch binding, obſerving to train them in an horizontal poſition, and at equal diſtances; being careful not to croſs any of the branches, nor to lay them in too thick: the diſtance I would allow for the branches of pears and apples, ſhould be proportioned according to the ſize of their fruit; ſuch of them whoſe fruit is large, as the ſummer boncretien, monſieur John, and beurre du roy pears, and the rennet guiſe, Holland pippin, French pippin, and other large apples, ſhould have their branches ſix or eight inches diſtance at leaſt; and to thoſe of leſſer growth four or five inches will be ſufficient.

But, beſides this ſort of eſpalier made with poles, there is another ſort that is by many people preferred; which is framed with ſquare timbers cut to any ſize, according to the ſtrength thereof, or the expence the owner is willing to go to; theſe, though they appear more ſightly, when well fixed and painted, are not of longer duration than one of the former, provided it is well made, and the poles are ſtrong which are ſet upright; nor will they anſwer the purpoſe better, though they are vaſtly more expenſive; for the greateſt beauty conſiſts in the diſpoſing the branches of the tree, which, eſpecially in ſummer, when the leaves are on, will entirely hide from the ſight the frame of the eſpalier: therefore all expence in erecting theſe is needleſs, farther than making proviſion to ſecure the branches of the trees in a regular order.

Fruit-trees thus planted, and well managed, are much preferable to thoſe trained up in any other figure, upon ſeveral accounts: as, firſt, theſe take up very little room in a garden, ſo as to be hurtful to the plants which grow

in the quarters; and, ſecondly, the fruit upon theſe are better taſted than thoſe which grow upon dwarfs, the ſun and air having freer acceſs to every part of the tree, whereby the dampneſs ariſing from the ground is ſooner diſſipated; which is of ſingular advantage to fruit-trees. *Miller's Gard. Dict.*

ESPLANADE, in fortification, the ſloping of the parapet of the covert-way towards the campaign.

ESPOUSALS, in law, ſignify a contract or promiſe made between a man and a woman, to marry each other.

ESQUIRE, *Armiger*, was anciently the perſon that attended a knight in time of war, and carried his ſhield.

ESSAY, in coinage, See the article ASSAY.

ESSAY, in literature, a peculiar kind of compoſition, the character of which is to be free, eaſy, and natural; not tied to ſtrict order or method, nor worked up and finiſhed like a formal ſyſtem.

ESSAY-HATCH is the miner's term for a little trench or hole, which they dig to ſearch for ſhoad or ore.

ESSENCE is that which conſtitutes the peculiar nature of any thing, and makes it to be what it is.

In philoſophy, the eſſence of a thing is that which is the primary conception which one has of it, and is diſtinguiſhed from its act, which is called its exiſtence. Thus the eſſence of a rectilinear triangle conſiſts in its being bounded by three ſtraight lines; of a circle, in that its radii or ſemi-diameters are all equal; and the eſſence of a ſquare is, that it hath four right angles and four equal right-lined ſides.

ESSENCE, in chemiſtry, is the moſt pure, balſamic, and ſubtile parts, which have been extracted from any body by means of fire.

ESSENES, or ESSENIANS, in Jewiſh antiquity, one of the three ancient ſects among that people, who outdid the Phariſees in their moſt rigorous obſervances. They allowed a future ſtate, but denied a reſurrection from the dead. Their way of life was very ſingular: they did not marry, but adopted the children of others, whom they bred up in the inſtitutions of their ſect: they deſpiſed riches, and had all things in common; and never changed their cloaths, till they were entirely worn out. When initiated, they were ſtrictly bound not to communicate the myſteries of their ſect to others; and if any of their members were found guilty of enormous crimes, they were expelled.

Pliny tells us, that they dwelt on the weſt ſide of the lake of Aſphaltites; that they were a ſolitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree: he adds, that they were conſtantly recruited by new comers, whom the ſurges of ill fortune had made weary of the world; in which manner the ſect was kept up for ſeveral thouſands of years, without any being born among them. The reaſon why we find no mention made of them in the New Teſtament, may be their recluſe and retired way of life, no leſs than their great ſimplicity and honeſty, whereby they lay open to no cenſure or reproof.

ESSENTIA, ESSENCE. See the article ESSENCE.

ESSENTIAL, ſomething neceſſarily belonging to the eſſence or nature of a thing, from which it cannot be conceived diſtinct: thus the primary qualities of bodies, as extenſion, figure, number, &c. are eſſential or inſeparable from them in all their changes and alterations. See the article QUALITY.

ESSOIN, in law, an excuſe for a perſon ſummoned to appear and anſwer to an action on account of ſickneſs or other juſt cauſe of his abſence.

ESSOIN-DAY is regularly the firſt day of every term, though the fourth day after is alſo allowed by way of indulgence.

ESSORANT, in heraldry, denotes a bird ſtanding on the ground with its wings expanded, as if it had been wet, and were drying itſelf.

ESTABLISHMENT *of Dower*, in law, an aſſurance of dower made to the wife by the huſband, or ſome friend of his, on marriage.

ESTATE, in law, ſignifies the title or intereſt that a perſon has in lands, tenements, or other effects; comprehending the whole in which a perſon hath any property, and will paſs the ſame.

ESTATES, in a political ſenſe, is uſed either to denote the dominions of ſome prince, or the general claſſes into which the people are divided.

ESTATES-GENERAL, in the polity of Holland. See STATES-GENERAL.

ESTETE, in heraldry, denotes the heads of beaſts torn off by main force.

ESTHER, a canonical book of the Old Teſtament, containing the hiſtory of a Jewiſh virgin, dwelling with her uncle Mordecai at Shuſhan, in the reign of Ahaſuerus, one of the kings of Perſia.

ESTOILEE, or CROSS ESTOILEE, in heraldry, a ſtar with only four long rays in form of a croſs; and accordingly, broad in the center, and terminating in ſharp points.

ESTOPPEL, in law, an impediment or bar to an action, which ariſes from a perſon's own fact; or rather, where he is forbid by law to ſpeak againſt his deed, which he may not do, even to plead the truth.

ESTOVERS, in law, is moſt generally taken for certain allowances of wood made to tenants, as houſe-bote, hedge-bote, and plough-bote; which three are comprehended under reaſonable eſtovers.

ESTRANGEL, ESTRANGELUS CHARACTER, in the Syriac grammar, a particular ſpecies or form of Syriac letters, ſerving as the majuſculæ letters of that language, and by ſeveral ſuppoſed to be the true ancient Chaldee character.

ESTRAY, in law, any beaſt, not wild, that is found within a lordſhip, and owned by no-body: in which caſe, being cried according to law in the two next market towns adjacent, and not claimed in a year and a day by the owner, it becomes the property of the lord of the manor or liberty wherein it was found.

ESTREAT, in law, a true copy, note, or duplicate of an original writing or record, eſpecially fines, amercements, penalties, &c. ſet down and impoſed in the rolls of a court, to be levied by the bailiff, or other officer.

ESTREPEMENT, in law, any ſpoil made by tenants for life on any lands, &c. to the prejudice of the reverſioner: it is alſo taken to ſignify the making land barren, by continual ploughing and ſowing, and thereby drawing out the heart of the ground without manuring, or rather good huſbandry, by which means it is impaired.

It may likewiſe be applied to the cutting down of trees, or lopping them farther than the law allows.

ESURINE SALTS, ſuch as are of a corroding, fretting, and eating nature; abounding chiefly in places near the ſea-ſide, and where great quantities of coals are burnt, as appears from the ſpeedy ruſting of iron-bars in the windows of houſes built in ſuch places.

ETAPPE, a term uſed, in the French armies, for the proviſions and forage allowed an army in their route through a kingdom, whether going into winter quarters, or returning to take the field. Hence, etapier is the undertaker or perſon who contracts with the country or territory for furniſhing the ſaid proviſions.

ETCHING, a method of engraving on copper, in which the lines or ſtrokes, inſtead of being cut with a tool or graver, are eaten in with aquafortis.

Etching is of a later invention, though not very modern, than engraving with the tool; of which it was at firſt only an imitation, that was practiſed by painters and other artiſts who could much ſooner form their hand to, and attain a faculty of, working in this way than with the graver. But being then nevertheleſs conſidered as a counterfeit kind of engraving, and therefore inferior to the other, it was cultivated in a very confined manner: the cloſeneſs of the reſemblance of the work to that performed by the tool, being made the teſt of its merit; and conſequently the principal object of aim in thoſe who purſued it. This ſervile confinement of the art of etching to the imitation of the original kind of engraving was a great cauſe of retarding its advance towards perfection: as many of the moſt able maſters cramped their talents with the obſervance of it: which may be ſeen in the inſtances of Sadelers, Swanneberg, Vilamene, and particularly Le Boſſe; who, in his treatiſe on engraving, has laid down as a principle, that the perfection of this kind conſiſts in the cloſe ſimilitude of the work with that done by the tool. This abſurd prepoſſeſſion has been ſince worn out: and the method of working with aquafortis has been ſo far improved, that inſtead of being now deemed a ſpurious kind of engraving, it evidently appears the foundation of an excellence in many modern works, that could never have been produced without it: ſince, though the neatneſs and uniformity of the hatches, which attend the uſe of the tool, is more advantageous with reſpect to portraits; yet the liberty and facility of the other manner give a much greater opportunity to exerciſe the force of genius and fancy in hiſtory painting; where the effect of the whole, and not the minute exactneſs in finiſhing all the parts, conſtitutes the principal value. There are two methods practiſed of engraving in this way; the one with a hard varniſh or ground; the other with a ſoft. The firſt was formerly much uſed, being better accommodated to the intention of imitating the engraving with the tool; as the firmneſs of the body of the varniſh gave more opportunity of retouching the lines, or enlarging them with the oval pointed needles, called by the French *echoppes*, as was practiſed by Le Boſſe and others for that purpoſe. The latter has now almoſt wholly ſuperſeded the uſe of the other by the free and ſupple manner of working it admits of; which gives a power of expreſſion incompatible with the greater inflexibility of the hard varniſh, that confines the lines and hatches to ſuch a regularity and ſameneſs, as give a ſtiffneſs of manner and coldneſs of effect to the work.

The mixture of the uſe of the tool and aquafortis, which are now both employed together in many caſes, has however given that perfection to engraving which it bears at preſent. The truth and ſpirit of the outline that the method of working with aquafortis affords, and the variety of ſhades which the different kinds of black producible in this way, as well as other means of expreſſing the peculiar appearance and character of particular ſubjects, furniſh what was defective in the ſole uſe of the tool; while, on the other hand, the exactneſs and regularity of the lines, which are required for finiſhing many kinds of deſigns, are ſupplied by the graver: and by a judicious application of both, that complete finiſhing is obtained, which either of them alone muſt neceſſarily want.

The manner by which this art is performed, is the covering the ſurface of the plate with a proper varniſh, or ground, as it is called, which is capable of reſiſting aquafortis; and then ſcoring or ſcratching away, by inſtruments reſembling needles, the parts of this varniſh or ground, in the places where the ſtrokes or hatches of the engraving are intended to be: when, the plate being covered with aquafortis, the parts that are laid naked and expoſed by removing the ground or varniſh, are corroded or eaten away by it, while the reſt, being ſecured and defended, remain untouched.

There are two methods of etching, as hath been already obſerved, the difference of which from each other conſiſts, as well in the difference of the varniſh or ground, as in that of the aquafortis, adapted to each kind: but the general methods of performing them is alike in both. Theſe varniſhes, or grounds, are diſtinguiſhed by the names of hard and ſoft: for, in their conſiſtence, or the reſiſtance they give to the needles, lies their eſſential variation from each other. The hard varniſh, it is with good reaſons conjectured, was not the firſt in uſe: but ſoon took place of the other; and was, for ſome time, the moſt received in practice, on the account of its admitting the work to be made more like that of the graver: the ſoft has however ſince, in its turn, prevailed to the excluſion of it in ſome degree, except in the caſe of particular ſubjects; but not ſo entirely as to take away the expedience of ſhewing how it is performed. The manner of etching with the ſoft varniſh is now, however, one of the moſt important objects of the art of engraving, and it is at preſent in univerſal uſe, ſometimes alone, but more frequently intermixed with the work of the tool; and, in ſome caſes, with great advantage, even where the whole is intended to paſs for being performed by the graver.

Preparation of the ſoft varniſh, according to Mr. Lawrence, an eminent Engliſh engraver at Paris.

"Take of virgin's wax and aſphaltum, each two ounces, of black pitch and Burgundy pitch, each half an

an ounce. Melt the wax and pitch in a new earthen-ware glazed pot; and add to them, by degrees, the aſphaltum finely powdered. Let the whole boil till ſuch time as that, taking a drop upon a plate, it will break when it is cold, on bending it double three or four times betwixt the fingers. The varniſh being then enough boiled, muſt be taken off the fire; and, letting it cool a little, muſt be poured into warm water, that it may work the more eaſily with the hands, ſo as to be formed into balls; which muſt be rolled up in taffety for uſe."

It muſt be obſerved, firſt, that the fire be not too violent, for fear of burning the ingredients; a ſlight ſimmering will be ſufficient: ſecondly, that while the aſphaltum is putting in, and even after it is mixed with them, the ingredients ſhould be ſtirred continually with the ſpatula; and thirdly, that the water, into which this compoſition is thrown, ſhould be nearly of the ſame degree of warmth with it, to prevent a kind of cracking that happens when the water is too cold.

The varniſh ought always to be harder in ſummer than in winter; and it will become ſo if it be ſuffered to boil longer, or if a greater proportion of the aſphaltum or brown reſin be uſed. The experiment abovementioned, of the drop ſuffered to cool, will determine the degree of hardneſs or ſoftneſs, that may be ſuitable to the ſeaſon when it is to be uſed.

Preparation of the hard varniſh uſed by Callot, commonly called the Florence varniſh.

"Take four ounces of fat oil very clear, and made of good linſeed oil, like that uſed by painters: heat it in a new pot of glazed earthen-ware, and afterwards put it to four ounces of grains of maſtick well powdered; and ſtir the mixture briskly, till the whole be well melted together; then paſs the whole maſs, through a piece of fine linen, into a glaſs bottle with a long neck, that can be ſtopped very ſecurely; and keep it for the uſe that will be below explained."

Method of applying the ſoft varniſh to the plate; and of blackening it.

The plate being well poliſhed and burniſhed, according to the directions given under the article of COPPER-PLATE, as alſo cleanſed from all greaſineſs by chalk or Spaniſh white, put it upon a chafing-diſh, in which there is a moderate fire; obſerving to hold it ſo, that it may not burn; to do which more commodiouſly, a prop is uſed; and ſometimes two, or even four, as will be obſerved. Theſe props ſhould be fixed to the edge of the plate, in ſome place where there is to be no engraving; and the plate being thus ſupported, muſt be left over the fire till it be ſo hot, that the varniſh being brought in contact with it, may melt, and run through the taffety which is wrapped round it: then take ſome of the ſoft varniſh, well wrapped up in taffety, that is free from all greaſe and dirt, as alſo ſtrong and ſound in every part; for indeed it ought to be new, that there may be no weak or worn place in it where the varniſh may run through in too great plenty; and rub the plate, fixed as before deſcribed over the fire, with it, till it grow hot: in doing which, it ſhould be gently paſſed from one ſide to the other in a right line, ſo as to form ſeveral rows, till ſuch time as the plate be every where moderately covered: after this, with a ſort of ball made of cotton tied up in taffety, beat every part of the plate gently, while the varniſh be yet in a fluid ſtate; and to unite it ſtill more, and give it a finer grain, it is proper to take the plate from the fire in an inſtant, and continue ſtriking it on every part with the ball, till it attain a harder conſiſtence in cooling. This muſt not, however, be prolonged till the varniſh be too cold; for then the ball would be apt to make it riſe from the plate.

When the plate is thus uniformly and thinly covered with the varniſh, it muſt be blackened by a piece of flambeau, or of a large wax candle, which affords a copious ſmoke; and ſometimes two, or even four, ſuch candles are uſed together, for the ſake of diſpatch; that the varniſh may not grow cold, if that were poſſible, during the operation. The plate muſt then be heated again, in order to the varniſh being blackened, that it may be in a melted ſtate when that operation is performed; but great care muſt be taken not to burn it; which, when it happens, may be eaſily perceived by the varniſh ſmoking and running into little lumps, as if it had contracted ſome foulneſs. The following expedient is made uſe of, for the more commodiouſly blackening the varniſh; being particularly neceſſary where the plates are large. Fix a ſtrong hook in the beams of the boards of the roofing of the room, through which paſs four pieces of cord of equal length, at the end of which are fixed four iron rings of about four inches diameter. The four props, which hold the corners of the plate, muſt be faſtened to theſe rings; and the plate, being thus ſuſpended in the air, with the varniſhed ſide downwards, may be blackened with great convenience: but this is not, however, abſolutely requiſite, but in the caſe of large plates that could not, without difficulty, be held up, unleſs this, or ſome other ſuch contrivance, were made uſe of.

It is proper to be very cautious in keeping the flambeau or candle at a due diſtance from the plate, for fear the wick may touch the varniſh, which would both ſully and mark it. If it appear that the black have not penetrated the varniſh, the plate muſt be again placed, for ſome little time, over the chafing-diſh; and it would be found, that in proportion as the plate grows hot, the varniſh will melt and incorporate with the black, which lay above it; in ſuch manner, that the whole will be equally pervaded by it.

Above all things, the greateſt caution ſhould be uſed in this operation, to keep all the time a moderate fire; and to move frequently the plate, and change the place of all the parts of it, that the varniſh may be alike melted every where, and be kept from burning. Care muſt alſo be taken, that during this time, and even till the varniſh be entirely cold, no filth, ſparks, or duſt, fly on it; for they would then ſtick faſt, and ſpoil the work.

Method of applying the hard varniſh on the plate, and of blackening and drying it.

The plate being perfectly cleanſed, and freed from greaſineſs, by the means before directed, it muſt be put on a chafing diſh, containing a ſmall fire; and when it is become moderately hot, it muſt be taken off again, in order to receive the varniſh, which muſt be thus laid on. Take a proper quantity of the varniſh; and putting it on the end of the finger, with a ſtick, or other ſmall inſtrument, touch the plate with it gently, in order that it may be ſpread in ſmall ſpots of the ſame ſize, at as equal diſtances as poſſible, over every part: and if the plate cool too much before the whole be finiſhed, heat it again as at firſt; carefully preſerving it from any duſt or foulneſs whatever, that may be liable to fall upon it: when this is done, having made the fleſhy part of the hand, below the little finger, thoroughly clean, beat gently with it on the plate, till all the ſpots of the varniſh are driven together, and cover equally and uniformly the whole extent of the poliſh ſurface.

After this beating the varniſh, the ſame part of the palm muſt be paſſed over it, in a ſliding direction, as if to clean it; in order to lay the varniſh yet more ſmoothly and equally. But the greateſt caution muſt be obſerved, on two accounts; the one, that the varniſh lie very thin on the plate; the other, that there be no ſweat on the hand, becauſe the moiſture would ſtick to the varniſh, and when it is to undergo the effect of the fire, would make, in boiling, little holes in it, that are almoſt inviſible; and which, without great care, when the aquafortis comes to exerciſe its force on the work that has been engraved, would, at the ſame time, exert its power on the copper, in theſe little holes.

The above are the directions given by M. Le Boſſe for performing this operation: but as ſpreading the varniſh on the plate with the hand is ſubject to great inconveniences, as he himſelf has remarked, in the inſtances of burning the hands, and which is ſcarcely poſſible to be avoided; and alſo the producing little imperceptible holes in the varniſh, which ſuffer the aquafortis to reach the plate in wrong places, and eat ſpots in many parts of the copper: to avoid theſe accidents, it is better therefore to ſpread the varniſh with a little ball, or puff, made of the cotton and taffety, as is done in the caſe of the ſoft varniſh.

The varniſh being then equally ſpread in this manner, the way to blacken it is, to take a large candle of good tallow, which is well lighted, and does not emit any ſparks; and to fix the plate over it, with the varniſhed ſurface downwards; ſupporting it by reſting one of the corners againſt a wall, and holding the other in the hand, and obſerving alſo that the fingers do not touch any part of the varniſh. The candle, by this means, being kept perpendicularly under it, the flame will riſe againſt the varniſh, and may be ſuffered to approach it as near as poſſible, provided the ſnuff do not touch it; and in this manner it muſt be moved under every part of the varniſh, till ſuch time as the whole ſhall be made ſufficiently black; but the candle ſhould be ſnuffed when there is occaſion, in order that it may afford its ſmoke more copiouſly. This being finiſhed, the varniſh muſt be baked or dried, in the following manner, care being taken in the mean time, to place it where it may be ſafely preſerved from all dirt.

The plate muſt be placed over a pan of burning coals, and continued there till the ſmoak from the varniſh begins to decreaſe, when the plate muſt be removed from the fire, and ſuffered to cool gradually.

The plate being thus prepared, the deſign muſt be drawn on it with proper needles; but if by ſome accident the varniſh ſhould happen to be ſcratched on any part of the plate, it muſt be repaired with a pencil dipped in Venetian varniſh, tempered with a little lamp-black, by which means the places that were accidentally ſcratched will be defended from the action of the aquafortis.

The next operation is that of corroding the plate with aquafortis, in order to which a border of ſoft ſealing-wax muſt be faſtened round the plate, about an inch high, in the form of a little wall or rampart; obſerving that the plate be well dried at the fire before this border be put round it. At one of the corners of this border a gutter is uſually made, which ſerves for pouring commodiouſly the aquafortis over the plate. The plate being thus bordered, take a due quantity of the refiners aquafortis, mix it with half its quantity of common water, and pour it gently through the trough or gutter made in the waxen border, till it riſe above a finger's breadth above the ſurface of the plate: when, if all things have been rightly conducted, it will be ſeen that the aquafortis will ſoon exert its action in the hatches which have been ſtrongly touched; but thoſe more weakly engraved will appear at firſt clear, and of the colour of the copper. The menſtruum muſt therefore be ſuffered to continue on the plate till its effects become viſible on the more tender parts, when the aquafortis ſhould be poured off, the plate waſhed with clean water, and dried before the fire: then take a ſmall pencil and dip it into a mixture of oil and tallow, and cover with it the lighter parts of the plate. This being done, the aquafortis muſt be again poured on, and ſuffered to continue a longer or ſhorter time, according to the ſtrength of the menſtruum, or the nature of the engraving, when it muſt be again poured off as before, and the plate immediately waſhed with water.

It may not be improper to obſerve, that, when the aquafortis is on the plate, the feathered part of a quill ſhould be uſed to cleanſe away the foulneſs of the verdigriſe that gathers in the hatches when the aquafortis operates on them, and to give it more room to exert its action; for by moving the aquafortis to and fro on the plate by the feathered part of the quill, and bruſhing away the black ſaline matter, where it appears to be formed, the hatches will be cleanſed, and the aquafortis exert its whole force equally on every part.

The plate being thus ſufficiently corroded by the aquafortis, and well waſhed with water, it muſt be warmed at the fire, and the border of wax removed; after which it muſt be made hotter till the mixture or compoſition, as well as the varniſh, melt, when it muſt be well wiped with a clean linen cloth, and afterwards rubbed heartily in every part with oil of olives; when it will be ready to be retouched and finiſhed by the graver. See the article ENGRAVING.

ETERNITY, an attribute of God, expreſſing his infinite or endleſs duration. See the article GOD.

ETHICS, or MORALITY, the ſcience of manners or duty, which it traces from man's nature and condition, and ſhews to terminate in his happineſs; or, in other words, it is the knowledge of our duty and felicity, or the art of being virtuous and happy.

ETHIOPIA, or ÆTHIOPIA, a very extenſive country of Africa, comprehending Abyſſinia, Nubia, and Abex; it is bounded by Egypt, and the deſart of Barca on the north; by the Red-ſea, and Indian ocean on the eaſt; by Anian, and the unknown parts of Africa on the ſouth; and by other unknown countries on the weſt.

ETHIOPIC YEAR. See the article YEAR.

ETHMOIDAL, in anatomy, is applied to one of the common ſutures of the ſkull, which goes round the os ethmoides, from which it derives its name, and which ſeparates it from the bones in contact with it.

ETHMOIDES, is an epithet applied to a bone at the root of the noſe, called alſo os ethmoides. See CRANIUM.

The word is Greek, ηθμοειδης, which is derived from ηθμος, a ſtrainer, and ειδος, form or likeneſs.

ETHNOPHRONES, in church hiſtory, hereties of the ſeventh century, who, profeſſing Chriſtianity, joined thereto all the ceremonies and follies of paganiſm, ſuch as judicial aſtrology, divinations of all kinds, &c. and who obſerved all the feaſts, times, and ſeaſons of the Gentiles.

ETHOPOEIA, or ETHOLOGY, in rhetoric, a draught, or deſcription, expreſſing the manners, paſſions, genius, tempers, aims, &c. of any perſon.

ETYMOLOGY, that part of grammar which explains the derivation of words, in order to arrive at their firſt and primary ſignification.

The word is formed of the Greek, ετυμος, true, and λογος, to ſay. Hence Cicero calls it *notatio* and *verilogium*. Quintilian calls it *originatio*.

A judicious enquiry into etymologies is of conſiderable uſe. The etymologiſt, by ſeeking the true and original reaſon of the ideas affixed to each word and expreſſion, may often furniſh an argument of antiquity for a language from the traces remaining thereof, compared with the ancient uſes. Beſides, etymologies are neceſſary for the thorough underſtanding of a language; for the force of a word is generally better conceived when a perſon knows its origin.

It is objected, however, that the art is altogether arbitrary; but the ſcience is certainly real, and as regular as divers others, and has its ſhare of difficulty: for it is no eaſy matter to go back into the Gauliſh and Britiſh ages, to follow, as it were, by the track, the various imperceptible alterations a language has undergone from the earlieſt ages.

An etymologiſt has need of all the light he can come at to bring down words variouſly diſguiſed in their paſſage, and remark all the changes that have befallen them: and as thoſe alterations have ſometimes been owing to caprice, it is eaſy to take a mere conjecture for a regular analogy; ſo that it is no wonder the public ſhould be prejudiced againſt a ſcience which ſeems to ſtand on ſo precarious a footing. Quintilian has ſhewn that the ancient etymologiſts, notwithſtanding all their learning, often fell, no leſs than the moderns, into very ridiculous deviations.

EVACUANTS, in medicine, are properly ſuch things as diminiſh the animal fluids by throwing out ſome morbid or redundant humour; or ſuch as thin, attenuate, and promote the motion and circulation thereof.

The word is Latin, from *evacuo*, to empty or cleanſe.

EVACUATION, in phyſic, the art of diminiſhing, emptying, or attenuating the humours of the body.

EVANGELISTS, at preſent, is confined to the writers of the four goſpels, St. Matthew, St. Mark, St. Luke, and St. John. The apoſtle Paul, enumerating the ſeveral orders of Chriſtians, according to the gifts beſtowed on them, reckons evangeliſts in the third place, after apoſtles and prophets, and before paſtors and teachers.

The word is formed from the Greek ευαγγελος, which is derived from ευ, well, and αγγελος, an angel, or meſſenger.

EVANID, a name given by ſome authors to ſuch colours as are of no long duration, as thoſe in the rainbow, in clouds before and after ſun-ſet, &c.

Evanid colours are alſo called fantaſtical and emphatical colours.

EVANTES, in antiquity, the prieſteſſes of Bacchus; thus called, by reaſon that in celebrating the orgia, they ran about as if diſtracted, crying, *evan, evan, ohé evan.*

EVAPORATION, in philoſophy, is the act by which the moiſture in any body is exhaled or evaporated, either by the heat of the ſun, or by means of fire.

The word is Latin *evaporatio*, and derived from *e*, out of, and *vapor*, a vapour.

EVAPORATION, in chemiſtry, is that operation whereby the more aqueous and volatile parts of fluids are evaporated or drove away in vapours, in order to render the remaining part of a higher conſiſtence than before.

EVASION, among lawyers, denotes a cunning or ſubtle endeavouring to ſet aſide, or eſcape the puniſhment of, the law.

EVATES, a branch or diviſion of the druids, or ancient Celtic philoſophers. Strabo divides the Britiſh and Gauliſh philoſophers into three ſects, bards, evates, and druids; but Marcellus and Hornius reduce them all to two ſects, viz. the bards and druids. See the articles BARDS and DRUIDS.

EUBAGES, an order of prieſts, or philoſophers, among the ancient Celtæ, or Gauls: ſome will have the eubages to be the ſame with the druids, and ſaronidæ of Diodorus; and others, that they were the ſame with what Strabo calls evates.

EUCHARIST, the ſacrament of the Lord's ſupper.

The word is Greek *ευχαριστια*, derived from *ευ*, well, and *χαρις*, favour or thanks.

In the beginning of Chriſtianity the whole church met together at the Lord's table, generally at their public aſſemblies, on Sundays always, beſides other days, eſpecially Saturday; on which day all the churches in the world, except Rome and Alexandria, uſed to celebrate their ſacrament. At firſt they adminiſtered the euchariſt every day; afterwards four times a week: but as the power of religion declined, it fell to thrice a year, as Chriſtmas, Eaſter, and Whitſuntide.

EUDISTS, a congregation of miſſionary prieſts, in France, aſſociated under the name and title of Jeſus and Mary.

EUDOXIANS, in church-hiſtory, a branch of Arians. See ARIANS.

EVE, the ſame with vigil. See VIGIL.

EVECTION *of the Moon*, the ſame with libration. See the article LIBRATION.

EVERARD's *Sliding-Rule*. See SLIDING-RULE.

EVER-GREEN, in gardening, a ſpecies of perennials, which continue their verdure, leaves, &c. all the year: ſuch are hollies, phillyria's, lauruſtinus's, bays, pines, firs, cedars of Lebanon, &c.

EVERLASTING-FLOWER, in botany, a name given to the amaranthoides.

EVERLASTING-PEA, a genus of plants, otherwiſe called lathyrus.

EVESDROPPERS, in law, perſons who ſtand under the eves, walls, or windows of a houſe by day or by night, to liſten after news, and carry it to others, thereby raiſing ſtrife and contention in the neighbourhood. They are puniſhable in the court-leet, or quarter-ſeſſions.

EUGENIA, the ſilver-tree, in botany, a genus of plants, the corolla of which conſiſts of four oblong, obtuſe, concave petals, twice as large as the cup: the fruit is a quadrangular, coronated drupe, containing only one cell: the ſeed is a roundiſh, ſmooth nut.

EVICTION, in law, ſignifies a recovery of lands, or tenements by law.

EVIDENCE. See CERTITUDE.

EVIDENCE, in law, is the teſtimony a perſon gives in a court upon any fact of which he has a perſonal knowledge.

EVIL, *Malum*, in philoſophy, &c. is either moral or natural.

Moral evil is the diſagreement between the actions of a moral agent, and the rule of thoſe actions, whatever it be.

Moral good and evil coincide with right and wrong, ſince that cannot be good which is wrong, nor that evil which is right.

Natural EVIL, whatever deſtroys, or any way diſturbs the perfection of natural beings: ſuch are blindneſs, diſeaſes, death, &c.

King's EVIL, in medicine, the ſame with the ſcrophula. See the article SCROPHULA.

EUMENIDES, furies, in antiquity. See the article FURIES.

EUNOMIANS, in church hiſtory, Chriſtian heretics in the fourth century. They were a branch of Arians, and took their name from Eunomius, biſhop of Cyzicus, who was inſtructed by Ætius in the points which were then controverted in the church, after having at firſt followed the profeſſion of arms. Eunomius ſo well anſwered the deſigns of his maſter, and declaimed ſo vehemently againſt the divinity of the Word, that the people had recourſe to the authority of the prince, and had him baniſhed; but the Arians obtained his recal, and elected him biſhop of Cyzicus. The manners and doctrines of the Eunomians were the ſame with thoſe of the Arians.

EUNUCHS, in church hiſtory, a ſect of heretics in the third century, who were mad enough to caſtrate, not only thoſe of their own perſuaſion, but even all others that they could lay hold of: they took their riſe from the example of Origen, who, miſunderſtanding the following words of our Saviour, — "And eunuchs who made themſelves eunuchs for the kingdom of heaven," caſtrated himſelf.

EVOLUTE, EVOLUTA, in the higher geometry, a curve firſt propoſed by Mr. Huygens, and ſince much ſtudied by the later mathematicians.

The evolute is a curve, ſuppoſed to be evolved or opened; and which, in opening, deſcribes other curves.

If a thread FCM (plate LXIV. *fig.* 4.) be wrapped or wound about the curve BCF, and then unwound again, the point M will deſcribe the curve AMM, which Mr. Huygens, the inventor, calls a curve deſcribed from evolution; and the curve BCF is the evolute, the part MC of the thread being called the radius of the evolute. 1. When the point B falls in A, the radius MC of the evolute is equal to the arch BC; but, if not, to AB + the arch BC. 2. The radius of the evolute CM is perpendicular to the curve AM. 3. Becauſe the radius MC of the evolute continually touches it, it is evident, from the generation of the curve deſcribed from the evolution, that it may be deſcribed through innumerable points, if the tangents in the parts of the evolute are produced until they become equal to their correſponding arches. 4. The evolute of the common parabola is a parabola of the ſecond kind, whoſe parameter is $\frac{27}{16}$ of the common parabola. 5. The evolute of a cycloid is another cycloid equal and ſimilar thereto. 6. All the arches of evolute curves are rectifiable, if the radii of the evolute can be expreſſed geometrically.

EVOLUTION, in arithmetic and algebra, implies the extraction of the roots of powers. See EXTRACTION.

The word is Latin, *evolutio*, formed of the prepoſition *e*, out; and *volvo*, I roll, or wind: q. d. an unwinding, or unrolling.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and diſpoſition, in order to preſerve a poſt, occupy another, to attack an enemy with more advantage, or to be in a condition of defending themſelves the better.

Naval EVOLUTIONS, the divers movements performed by fleets or ſquadrons at ſea, in ranging or forming into ſuch lines or poſitions as may be thought moſt proper or expedient, either by engaging, defending, or retreating, to the greateſt advantage. This term ſeems to have been firſt applied to the manœuvres of fleets by P. L'Hoſte.

The different expeditions an admiral may be ordered upon, as well as the various circumſtances that occur in conducting a fleet, firſt gave riſe to the ſeveral lines or orders of which it is formed, whoſe motions form what is called evolutions. See the articles LINE, DIVISION, and SQUADRON.

Thoſe who have any knowledge of the marine will undoubtedly allow, that the art of naval evolution is abſolutely

lutely neceſſary; ſince this art conſiſts only in the manner of regulating the ſeveral movements of a naval armament. Without this art it reſembles that of the moſt barbarous nations who have not the leaſt knowledge of war, who act without any other rule or order than what their wild ungoverned imaginations ſuggeſt to them, or chance throws in their way. Without a proper knowledge of the art of evolutions, an admiral will diſpoſe of his fleet very imperfectly, whether in oppoſing the enemy, cutting them off, doubling upon, avoiding or chacing them to the greateſt advantage; for all theſe things require that an admiral ſhould move each part of his fleet, as the mind moves the different members of the human body.

EUONYMUS, the ſpindle-tree, in botany, a genus of plants, the corolla of which conſiſts of four ovated, plane, and patent petals, longer than the cup: the fruit is a ſucculent, coloured capſule, of a quadragonal figure, formed of four valves, terminating in four points, and forming four cells: the ſeeds are ſingle, of an oval figure, and covered with a calyptra.

EUPATORIUM, hemp-agrimony, in botany, a genus of plants, the compound corolla of which is uniform and tubuloſe; the hermaphrodite flowers are equal; the partial flower is infundibuliform: the fruit is naked, only covered by the cup: the ſeeds are oblong, and crowned with a plumoſe down.

EUPHEMISM, *ευφημισμος*, in rhetoric, a figure which expreſſes things in themſelves diſagreeable and ſhocking; in terms implying the contrary quality.

EUPHONY, *ευφωνια*, in grammar, an eaſineſs, ſmoothneſs, and elegance in pronunciation.

Euphony is properly a figure, whereby we ſuppreſs a letter that is too harſh, and convert it into a ſmoother, contrary to the ordinary rules: of this there are abundance of examples in all languages.

EUPHORBIUM, a gummy reſinous concrete juice, exuding from an oriental, prickly, lacteſcent ſhrub of the ſame name.

There are many different ſpecies of the Euphorbium plant, natives of Africa, and preſerved in Europe in the hot-houſes of the curious. Whether the officinal gummy reſin of that name is extracted from one particular ſpecies, or from ſeveral promiſcuouſly, is uncertain. It is commonly ſuppoſed to be the produce, chiefly of that called by Breynius *Euphorbium cerei effigie, &c.* Euphorbium reſembling the cereus or torch-thiſtle, with thicker ſtalks armed with long ſpines: what Ray calls the true Euphorbium of the ancients is the ſpecies deſcribed in the *Hortus Malabaricus*, there named Schadidacalli, and by Breynius *Euphorbium Indicum, &c.* that is, Indian Euphorbium, reſembling the opuntia or prickly pear, with a triangular jointed ſtalk.

The juice is extracted by wounding the ſtem in different parts, pieces of ſheep-ſkin being previouſly tied round near the bottom, to prevent its running down upon the ground: the inciſions are made with a long handled inſtrument, that the operator may receive no injury from the cauſtic liquor ſpurting upon the face, &c. The juice concretes into roundiſh, ſemi-tranſparent whitiſh tears, which for the moſt part are internally hollow: theſe are the Euphorbium brought to us. We commonly find bits of the ſtalk, prickles, and ſeeds of the plant intermixed, and not unfrequently ſmall ſtones and ſand. The whitiſh or pale yellowiſh tears are preferred, as being the freſheſt; the browner or darker-coloured they appear, the longer they have been kept.

Euphorbium is in taſte extremely acrimonious: the ſlighteſt touch burns and corrodes the tongue: received in ſmall quantity into the noſe, it occaſions violent ſneezing: the utmoſt caution is requiſite in pulverizing it, to guard the eyes, noſe, and mouth, from the pernicious effects of the fine duſt that flies off.

The acrimony of Euphorbium ſeems to reſide in the more ſubtile parts of the reſin, which are extracted wholly by ſpirit of wine, and almoſt wholly by water, the reſin and gum being nearly in equal proportions.

The extreme acrimony of this drug renders it abſolutely unfit for any internal uſe: ſeveral correctors have indeed been propoſed for abating its virulence, but the beſt of them are not to be truſted to. It is employed only, and that but ſeldom, for external purpoſes; in ſtimulating unguents and plaſters for paralytic limbs, carious bones, and beginning ſchirrous tumours. Some have ventured on a minute portion of it, mixed with other powders, as an errhine, in obſtructions of the noſtrils, and mucous diſorders of the head; a practice by no means adviſeable, as we are in no want of medicines for theſe purpoſes, equally effectual, and far more ſafe.

EUPHRASIA, eye-bright, in botany, a genus of plants, the corolla of which conſiſts of a ſingle ringent petal; the tube is of the length of the cup; the upper-lip is concave and emarginated; the lower one is patent, and divided into three ſegments: the fruit is an ovato-oblong, compreſſed capſule, forming two cells: the ſeeds are numerous, very ſmall, and of a roundiſh figure.

This plant is an ophthalmic and cephalic, and good for a weak memory.

EUROPE, the leaſt of the four grand diviſions of the earth, is ſituated between the 36th and 72d deg. north latitude; and between the 10th degrees weſt long. and 65th eaſt long. being about 3000 miles long from north to ſouth, and 2500 miles broad from eaſt to weſt. It is bounded by the Frozen ocean on the north; by Aſia on the eaſt; by the Mediterranean, which ſeparates it from Africa, on the ſouth; and by the Atlantic ocean on the weſt.

Europe is commonly ſubdivided into three grand diviſions, north, middle, and ſouth. The north or upper diviſion comprehends Ruſſia or Muſcovy, Sweden, Denmark, and Norway, and the iſlands of Britain, Iceland, Greenland, and thoſe of the Baltic. The middle diviſion contains Poland, Germany, and the hereditary dominions of the houſe of Auſtria, the Low Countries, or Netherlands, and France. The ſouthern diviſion comprehends Turky in Europe, the ancient Greece chiefly, Switzerland, Italy, Spain, and Portugal, and the iſlands of Sicily, Sardinia, Corſica, Majorca, Minorca, Ivica, and thoſe of the Archipelago.

EURYTHMY, in architecture, ſculpture, painting, &c. is a kind of majeſtic appearance, an inexpreſſible elegance and eaſineſs in the compoſition of all the members of a body, building, or picture, that reſults from their fine proportion and correſpondence with each other.

The word is Greek, *ευ*, eaſily, and *ρυθμος*, number, order.

EUSEBIANS, a name given to the Arians. See the article ARIANS.

EUSTATHIANS, the ſame with the catholics of Antioch, in the fourth century, ſo called from their refuſing to acknowledge any other biſhop beſide St. Euſtathius, who was depoſed by the Arians.

EUSTYLE, in architecture, is a ſort of building in which the pillars are placed at the moſt convenient diſtance one from another, the intercolumniations being all juſt two diameters and a quarter of the column, except thoſe in the middle of the face, before and behind, which are three diameters diſtant.

The word is Greek *ευστυλος*, and derived from *ευ*, proper, and *στυλος*, a column.

EUTYCHIANS, in church hiſtory, heretics in the fifth century, who embraced the errors of the monk Eutyches, maintaining that there was only one nature in Chriſt. The divine nature, according to them, had ſo entirely ſwallowed up the human, that the latter could not be diſtinguiſhed; inſomuch that Jeſus was merely God, and had nothing of humanity but the appearance. This herely was condemned in a council held at Conſtantinople in 448, which ſentence was confirmed by the general council of Chalcedon, in 451.

EWE, the Engliſh name of a female ſheep. See the article SHEEP.

EWRY, in the Britiſh cuſtoms, an office in the king's houſhold, which has the care of the table linen, of laying the cloth, and ſerving up water, in ſilver ewers, after dinner.

EXACERBATION, the ſame with paroxyſm. See the article PAROXYSM.

EXACTION, in law, a wrong done by an officer, or a perſon in pretended authority, in taking a reward or fee that is not allowed by law.

EXÆRESIS, in ſurgery, is the removing any thing hurtful or ſuperfluous out of the body.

The word is Greek, from ἐξ, out of, and αἱρεω, to take.

EXAGGERATION, in rhetoric, is a kind of hyperbole, whereby things are augmented or amplified, by ſaying more than the truth, either as to good or bad.

The word is Latin, *exaggeratio*, and derived from *ex* and *agger*, a bank.

EXALTATION, in aſtrology, is a dignity which a planet acquires in certain ſigns or parts of the zodiac, which dignity is ſuppoſed to give it an extraordinary efficacy and influence. Thus the 15° of Cancer is the exaltation of Jupiter, according to Albumazar; that of the ſun is the 19° of Aries, and that of the moon is in Taurus.

EXAMINATION, in ſea affairs, a ſort of naval catechiſm, compoſed of various queſtions put by a committee of veteran ſea-captains to the midſhipmen, to diſcover whether they are ſufficiently qualified in the knowledge of their profeſſion to become a lieutenant.

EXAMINERS, in chancery, two officers of that court, who examine, upon oath, witneſſes produced in cauſes depending there, by either the complainant or defendant, where the witneſſes live in London, or near it. Sometimes parties themſelves, by particular order, are examined.

EXANTHEMA, in medicine, is a puſtule or eruption on the ſkin, as the meaſles, ſmall-pox, &c. and is generally attended with a fever, and terminates in a raſh.

The word is Greek, ἐξανθημα, which is derived from ἐξ, out of, and ἀνθεω, to flower.

EXARCH, ἐξαρχος, in antiquity, an officer ſent by the emperors of the Eaſt, into Italy, in quality of vicar, or rather præfect, to defend that part of Italy which ſtill continued under their obedience, and particularly the city of Ravenna, againſt the Lombaids.

EXCELLENCY, a title anciently given to kings and emperors, but now to ambaſſadors, and other perſons, who are not qualified for that of highneſs, and yet are to be elevated above the other inferior dignities.

EXCENTRIC, or ECCENTRIC, in geometry, are circles that have not the ſame center.

The word is Latin, *excentricus*, and is derived from *ex*, out of, and *centrum*, a center.

The excentric circle in the Ptolemaic ſyſtem is alſo called deferent, becauſe it ſeems to carry the planet round in its circumference. The orbit of the ſun is excentric with regard to the terreſtrial globe; that is, it does not revolve round the ſame center.

EXCENTRIC, in the new aſtronomy; inſtead of the excentric circles in the Ptolemaic ſyſtem, the moderns have ſuppoſed oval or elliptic ones, in order to explain the apparent irregularity of the planets, and their different diſtances with regard to the earth.

EXCENTRIC *Equation*, in the old aſtronomy, is an angle made by a line drawn from the center of the earth, and another drawn from the center of the excentric to the body or place of any planet; it is the ſame with the proſtaphæreſis, and is equal to the difference, accounted in an arch of the ecliptic, between the ſun's or planet's real and apparent place.

EXCENTRIC *Place of a Planet* is the true point of the orbit upon which the circle of inclination coming from the place of a planet in its orbit, falls thereon at right-angles. Mars is very excentric with regard to the ſun.

Anomaly of the EXCENTRIC. See the article ANOMALY.

EXCENTRICITY, or ECCENTRICITY, in the Ptolemaic aſtronomy, is that part of the linea apſidum lying between the center of the earth and of the excentric; or it is that circle which the ſun is ſuppoſed to move in about our earth, and which has not the earth exactly for its center. And this the ancients found muſt be ſuppoſed, becauſe the ſun ſometimes appears large, and then it is neareſt to us; and ſometimes ſmaller, and then it is farther off.

EXCENTRICITY *of the Earth*, in the new aſtronomy, is the diſtance between the focus and the center of the earth's elliptic orbit.

Mr. Whiſton, in his *Prælect. Aſtron.* page 90, ſhews the method of finding this from the apparent motion of the ſun, compared with the two extremes of the apſides; for ſince the true velocity of the earth in her aphelion and perihelion is in a reciprocal ratio of her diſtances from the ſun; and that the apparent and angular velocity is in a duplicate ratio of her diſtances reciprocally; from the apparent difference of theſe two velocities, the difference of the diſtances, or the double excentricity, will eaſily be known. The excentricity of the whole diſtance is, at a mean, about a ſixtieth part, or more accurately .01786.

EXCEPTION, in law, denotes a ſtop or ſtay to an action, and is either dilatory or peremptory, in proceedings at common law; but in chancery it is what the plaintiff alleges againſt the ſufficiency of an anſwer, &c.

EXCEPTION *to Evidence* is where a demurrer is offered in any civil cauſe, for the inſufficiency of the evidence given, and the court does not agree to it; in ſuch caſe, the court, upon requeſt, is to ſeal a bill of exceptions to the evidence, which may be heard on a writ of error.

EXCEPTIONS *in Deeds and Writings*, is the ſaving a particular thing out of a general one granted by deed; as a room, ſhop, or cellar, out of a houſe; a field, or timber trees, out of land, &c.

EXCERPTA, in matters of literature. See EXTRACT.

EXCESS, in arithmetic and geometry, is the difference between any two unequal numbers or quantities, or that which is left after the leſſer is taken from or out of the greater. See SUBTRACTION.

EXCHANGE, in a general ſenſe, implies a contract or agreement whereby one thing is given or exchanged for another.

EXCHANGE, in commerce, is the trade of money carried on between one place and another, by means of bills of exchange.

The things neceſſary to be conſidered in exchange are; 1. The real monies of each country or trading town. 2. Their imaginary monies. 3. The par of exchange.

1. By real money is meant a certain quantity of metal coined by the authority of a ſtate, and current at a certain value, by virtue of that authority.

2. By imaginary money we are to underſtand all denominations uſed to expreſs ſuch ſums as have no real ſpecies, or coin, of the value of any of theſe denominations.

1. The real monies of England.

Gold coins.	£.	s.	d.
A guinea, valued at	1	1	0
A half guinea	0	10	6
A quarter guinea	0	5	3
Silver coins.			
A crown, valued at	0	5	0
A half crown	0	2	6
A ſhilling	0	1	0
A ſixpence	0	0	6

Copper coins.

The half-penny, and the farthing, four of which make a penny.

Imaginary monies.

The pound, equal to twenty ſhillings.
The mark, equal to thirteen ſhillings and four pence.
The angel, equal to ten ſhillings.
The noble, equal to ſix ſhillings and eight pence.
The penny, equal to four farthings.

2. The real monies of Holland.

Gold coins.	Florins
A ducat, or ducatoon, valued at	20
A ſovereign	15
A roſe noble	11

Silver and copper coins.	Stivers
A ducatoon, valued at	63
A dric gulden	60
A rix-dollar	50
A crown	40
A dollar	30
A guld florin	28
A ſchilling or ſhilling	06
A ſtiver	01

Imaginary monies.

The guilder, or florin, of twenty ſtivers, or 240 groots.

The pound Flemiſh, of twenty ſhillings, or ſix guilders.

The groot, or penny Flemiſh, of half a ſtiver, or eight pfennicks.

The pfennick, or pfenning, or denier, $\frac{1}{16}$ of a ſtiver.

At Amſterdam, Rotterdam, Middleburg, &c. they keep their accounts either in guilders, ſtivers, and pfennicks, or pounds, ſhillings, and pence Flemiſh; which are divided as ours, viz. their pound into twenty ſhillings, and their ſhilling into twelve pence.

They exchange with London upon the pound ſterling, giving for it, when at par, 10 guilders; or, which is the ſame thing, thirty-three ſhillings and four pence Flemiſh.

The courſe of exchange runs between thirty and thirty-eight ſhillings Flemiſh per pound ſterling.

In Hamburgh and Antwerp too, they keep their accounts and exchange with London, in the ſame manner as with Holland.

London exchanges alſo with Denmark, Norway, Sweden, Muſcovy, Germany, Switzerland, Savoy, &c. but it is commonly done by the way of Hamburgh, Amſterdam, or Antwerp.

3. The real monies of France.

Gold coins.	Livres
Double louis d'or	22
Louis d'or	11
Half louis d'or	05 $\frac{1}{2}$

Silver coins.

Ecu or crown	3
Half ecu	1 $\frac{1}{2}$

They have alſo a $\frac{1}{3}$ ecu and $\frac{1}{10}$ ecu.

Braſs coin.

The only braſs coin is the ſol, twenty of which make a livre.

Copper coins.

The liard or farthing, four of which make a ſol.

The denier, twelve of which make a ſol.

The double, which was coined for a double denier, but paſſes now for a liard.

Imaginary monies.

The piſtole equal to ten livres.

The livre equal to twenty ſols, or $\frac{1}{3}$ of an ecu.

At Paris, Lyons, Rouen, &c. they keep their accounts in livres, ſols, and deniers; and exchange upon the ecu, or crown; the par of which, in ſterling money, is four ſhillings and ſixpence.

But it is to be obſerved, that the kings of France often raiſe the ſpecies of the kingdom, to rates conſiderably higher than thoſe for which they were at firſt coined, and conſequently far above their intrinſic value: ſo that a crown in ſpecie will paſs at four, five, or ſix livres. And three ſuch livres are ſtill named an ecu, or crown, though of a far leſs value than the ecu blanc, or white crown, that is, a crown in ſpecie. Hence it happens that the exchange is very variable, and falls low in proportion to the riſing of the French money above the intrinſic worth of the ſpecies.

The courſe runs between twenty-five and forty pence ſterling per crown, or between twenty and thirty livres per pound ſterling.

N. B. The French add the term tournois to their money, to diſtinguiſh it from the money of other nations, in the ſame manner as the Engliſh add the word ſterling to theirs.

The money of Spain is of two ſorts, viz. of plate and of bullion; the plate-money is of good ſilver, never changes its price, and is reckoned more than twenty per cent. better than the money of bullion, which is a mixture of ſilver and braſs, and as often varying in its price. In many places they buy and ſell in rials of bullion, but when they ſtate the accounts in their books, they commonly reduce them, by an allowance of ſo much per cent. to rials of plate.

4. The real and imaginary monies of Spain.

Gold coins.	Mervadies
A piſtole valued at four peſos, or pieces of eight, or at	1088
An half piſtole, at two peſos, or	544

Silver coins.

A peſo, or piece of eight, $\frac{8}{8}$ at	272
A rial, at	34

A mervadie is a ſmall piece of braſs or copper, five of which and about $\frac{1}{17}$, are, in value, equal to an Engliſh penny.

The imaginary ducat, in exchange, is valued at 375 mervadies, but in buying and ſelling it is only accounted 374.

In Madrid, Seville, &c. they keep their accounts in rials and mervadies, and exchange upon the piece of eight, the par of which, with London, is four ſhillings and ſixpence; but the courſe of exchange runs between fifty-two pence and ſeventy-two pence ſterling.

5. The real monies of Portugal.

	Rees.
Broad ducat of gold, valued at	1000
Double piſtole	4000
Piſtole	2000
Half-piſtole, or mil-ree	1000
Stamped patacoon	600
Current patacoon	500
Stamped cruſade	500
Current cruſade	400
Stamped piſo	480
Teſton	100

There are alſo the fractions of a teſton, at 80, 60, 40, 20, and 10 rees, which are of a mixed metal, compoſed of ſilver and braſs.

There are ſeveral other ſpecies in Portugal; ſuch as the moidore, a gold coin, valued at twenty ſeven ſhillings ſterling; the John, or Joannes, which is alſo gold, worth thirty-ſix ſhillings; the half Joannes and quarter Joannes; as alſo the double Joannes, valued at three pound twelve ſterling, &c.

In Liſbon, Oporto, &c. they keep their accounts in rees, and exchange in the half piſtole, or mil-ree; the par of which is about ſix ſhillings and eight-pence half-penny ſterling; but the courſe of exchange runs commonly betwixt fifty and eighty-pence ſterling per mil-ree.

6. The ſpecies or coins of Italy are very numerous, and would require more room than can be ſpared in this place: paſſing, therefore, the real monies, we ſhall only ſhew the manner of exchange between London and Genoa, Leghorn, Milan, Venice, and Rome.

At Genoa, they keep their accounts in lires, ſoldi, and deniers; reckoning twelve deniers to a ſoldi, and twenty ſoldi to a lire; and exchange upon the peyzo, of five lires, whoſe par is about four ſhillings and ſixpence ſterling: and the courſe of exchange is from forty-ſix to ſeventy-ſix and ſeventy eight pence per peyzo.

At Milan they keep their accounts in the ſame manner, but exchange upon the ducat, of five lires fifteen ſoldi. The courſe of exchange runs from fifty-five to ſixty-ſeven pence ſterling per ducat.

At Venice, merchants keep their accounts in lires, ſoldi, and pichioli; reckoning twelve pichioli to the ſoldi, and twenty ſoldi to the lire. But the bank reckons by ducats and groſſes. The ducat conſiſts of twenty-four groſſes. They exchange upon the ducat; the par of which is four ſhillings and eight-pence halfpenny ſterling, and the courſe is from fifty-two to ſixty-nine pence ſterling per ducat bancho.

Rome exchanges with London upon the ſcudi, whoſe par is about five ſhillings and ſixpence ſterling, and the courſe is from fifty-five to ſixty-five pence ſterling per ſcudi.

7. In

7. In the plantations of America, they reckon their monies, and keep their accounts, the ſame way as they do in Britain. But their money is of far leſs value: for bills upon London from any of the Caribbee-Iſlands are uſually charged with 25 per cent. in favour of London; that is, if St. Chriſtopher's, Montſerrat, Antigua, &c. ſhould draw upon London 100 l. the merchants of London charge the drawer with 125 l. for the ſaid 100; and for Jamaica, Virginia, Maryland, Penſilvania, New-England, &c. the difference is commonly greater.

London exchanges alſo with Ireland; but the courſe of exchange varies according to the demand of money or bills; it is commonly between four and fifteen per cent. loſs to Ireland, or in favour of London.

The end and deſign of Exchange is, to avoid the risk, and ſave the expence of transferring money.

The conſequence is, that bills of exchange repreſent money ſo effectually, that there is no difference between the one and the other. An example will ſet theſe propoſitions in a clearer light.

Let us ſuppoſe Peter of London debtor to Paul of Paris for goods received, and, at the ſame time, that Anthony of Paris has bought of James of London goods of an equal value: if the two creditors, Paul of Paris and James of London, exchange their debtors, a tranſfer of money is needleſs. Let Peter of London pay to James of London the ſum he owes to Paul of Paris, and let James for the ſaid ſum transfer to him, by an order in writing, that which he has at Paris in the hands of Anthony. Peter, the proprietor of this order, will transfer it to Paul his creditor at Paris, and Paul, on preſenting it to Anthony, will receive caſh for it.

If no merchant of Paris had owed money in London, Peter would have been under the neceſſity of ſending over money to Paris to pay his debt: or, if James had ſold, at Paris, only to half the value that Peter was indebted there, the half of Peter's debt would have been acquitted, the other half by ſending over the ſpecie.

It is evident, therefore, that exchange ſuppoſes reciprocal debts, that without them it could not exiſt, and that it conſiſts in the exchange of the debtors.

The example propoſed proves alſo, that the object, end, and deſign of exchange, is to ſpare the hazard and expence of transferring money. Let us ſuppoſe the debt between the two 100 l. and value the risk and charges on merchandiſe in trade at 40 l. it is plain each muſt pay 110 l. inſtead of 100 l. without an exchange of debtors.

The conſequence is alſo completely demonſtrated by this example, for the bill of Exchange drawn by James of London, or Anthony of Paris, was ſo effectually the ſign of money, that Paul of Paris, to whom it was ſent, has actually received 100 l. on preſenting it.

For underſtanding the par of exchange, it muſt be obſerved, that it has been found convenient, in the fabrication of monies, to mix a certain quantity of baſer metal, called alloy, with the pure gold and ſilver; and the proportion of alloy is different in different kingdoms: and accordingly, the coins are ſaid to be of a different degree of fineneſs; and two coins, though of a different weight, that have an equal quantity of pure gold or ſilver, are ſaid to be at par. And upon a computation it has been found, that the quantity of pure ſilver in an Engliſh crown is as 9 to 10; and therefore the par of the French crown is, in ſterling-money, four ſhillings and ſixpence. In like manner are other coins to be compared, in order to have their par determined.

The cauſes of the alteration of the par of exchange, are the alteration of public credit, and the abundance, or ſcarcity of credits of one country upon another.

A variation in the current coin is an example of the variation which the loſs of public credit makes in the par of exchange: although, at the very inſtant this change was made in the current coin, a new real par of exchange commenced, yet, the public credit declining, on account of the uncertainty of the property and the ſpecie not circulating, what repreſents the ſpecie muſt of courſe be under its value.

The ſecond cauſe of the alteration of the par of exchange, is the abundance or ſcarcity of credits of one country upon another; and this abundance or ſcarcity proceed in general from two cauſes.

One is the neceſſity that obliges the body politic of a ſtate to tranſport large ſums into foreign countries, as in caſe of a war.

The other lies in the proportion of the current mutual debts of private perſons in each ſtate.

The private perſons of two nations may contract two kinds of reciprocal debts.

The inequality of reciprocal ſales will form a firſt kind of debts.

If one of the two nations has a great deal of money at lower intereſt than the other, the rich private perſons in the former nation will buy up all the public ſecurities of the other, becauſe they will receive more intereſt for their money: the product of this intereſt, which muſt be paid every year, forms a ſecond ſpecies of debts: this may be looked upon as the product of a commerce, becauſe the national funds are negotiated; and, if you obſerve attentively, this is not a matter of ſpeculation only; in this caſe and ſeveral others, money is the merchandiſe, and thus theſe two debts belong properly to what is called the balance of trade, and will occaſion an abundance or ſcarcity of the credits of one country upon another.

When two nations would ſettle the balance of their commerce, that is, pay their reciprocal debts, they have recourſe to the exchange of debtors; but if the reciprocal debts are not equal, the exchange of debtors will only pay a part of theſe debts, the ſurpluſage or balance of trade muſt be paid in ſpecie.

The deſign and intention of exchange is to ſave the expence and hazard of tranſporting money; conſequently, every private perſon, before he determines on this method of trade, will ſeek credits on the country where he ſtands indebted.

Theſe credits will be dear in proportion to the difficulty of acquiring them, and conſequently, to have the preference, we are obliged to pay above their real value; if the credits are eaſy to come at, we ſhall pay under their value.

Let us ſuppoſe the merchants of Paris owe the manufacturers of Rouen 20,000 livres, and that the manufacturers of Rouen owe the bankers of Paris 10,000 livres; to ſatisfy theſe demands, we muſt make a bill of exchange for the 10,000 livres, the reciprocal debts between Paris and Rouen, and ſend the other 10,000 livres from Paris to Rouen.

Let us rate the charge and hazard of ſending this ſum at five livres per m. Every merchant in Paris will try to ſave this expence, and will ſeek to purchaſe a credit of a 1000 livres on Rouen; but as theſe credits are ſcarce, and difficult to procure, he will gladly give 1004 livres for a draught of 1000 livres on Rouen, and ſave one livre per m. thus the ſcarcity of bills of exchange on Rouen will lower the price of this exchange four livres per m. under par.

EXCHANGE ſignifies alſo a place in moſt conſiderable trading cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other perſons concerned in commerce, meet on certain days, and at certain times, in order to confer and treat together of matters relating to exchanges, aſſurances, freightments, and other mercantile negociations both by ſea and land.

Theſe aſſemblies are held with ſo much exactneſs, that the abſence of a merchant, &c. makes him ſuſpected of drawing to a failure or bankruptcy, as not being able to ſtand the change.

EXCHANGERS are ſuch as return money by bills of exchanger

EXCHEQUER, in the Britiſh juriſprudence, an ancient court of record, in which all cauſes concerning the revenues and rights of the crown are heard and determined, and where the crown revenues are received.

It took this name from the cloth that covered the table of the court, which was party-coloured, or chequered.

Black Book of the EXCHEQUER, a book containing a deſcription of the court of England in 1175, and its officers, with their ranks, wages, privileges, perquiſites, &c.

&c. alſo the revenues of the crown, both in money and cattle.

EXCISE, a certain duty or impoſt, charged upon liquors, as beer, ale, cyder, perry, malt, &c. and ſeveral other commodities, within the kingdom of Great Britain, and town of Berwick upon Tweed.

The exciſe is one of the moſt conſiderable branches of the king's revenues. It was formerly farmed out, but is now managed for the king by commiſſioners in both kingdoms, who receive the whole product of the exciſe, and pay it into the exchequer. Theſe commiſſioners are nine in number in England, and four in Scotland. The former have a ſalary of 1000 l. a year, the latter 500 l. They are obliged by oath to take no fee or reward, but from the king himſelf; and from them there lies an appeal to five other commiſſioners, called commiſſioners of appeals.

EXCLAMATION, in rhetoric, is an elevation of the voice which expreſſes the vehemence of any paſſion, as ſurpriſe, joy, admiration, indignation, grief, fear, deſire, &c. In Engliſh the interjections o! oh! alas! &c. are generally uſed in exclamation, in Latin oh! heu! ah! vah! &c.

The word is Latin, and derived from *exclamo*, to cry out.

EXCOMMUNICATION, an eccleſiaſtical penalty or cenſure, whereby ſuch perſons as are guilty of any notorious crime or offence are ſeparated from the communion of the church, and deprived of all ſpiritual advantages.

EXCOMMUNICATO CAPIENDO, a writ iſſued from the chancery upon the biſhop's certifying an excommunication.

EXCORIATION, in medicine and ſurgery, the galling or rubbing off of the cuticle, eſpecially of the parts between the thighs and about the anus.

EXCORTICATION, the ſame with barking of trees. See the article BARKING.

EXCREMENT, whatever is diſcharged out of the body of animals, after digeſtion, or whatever is otherwiſe ſuperfluous or noxious in them. Urine and the fæces are the groſs excrements that are diſcharged out of the bladder or belly. Phyſicians likewiſe call excrement the various humours that are ſecreted from the blood through the various ſtrainers in the body, and which ſerve for ſeveral uſes, ſuch as the ſaliva, ſweat, bile, the pancreatic juice, lymph, the ſemen, nails, the hair, the horns and hoofs of animals.

The word is Latin *excrementum*, which is derived from *excreo*, to ſpit or ſpawl.

EXCRESCENCE, in ſurgery, is any ſuperfluous matter that grows preternaturally upon the human or any other body, as wens, warts, or any ſort of ſwelling, particularly a fleſhy tumour.

The word is Latin, *excreſcentia*, which is derived from *excreſco*, to ſhoot or grow out.

EXCRETION, in medicine, is the act of ſeparating excrements, or excrementitious humours, from the aliments or blood.

The word is Latin, *excretio*, which is derived from *ex*, out of, and *creo*, to chooſe.

EXCRETORY, in anatomy, is a term applied to certain little ducts or veſſels which make part of the ſtructure of the glands, being the ſmall tubes through which the humours ſeparated into the glands are diſcharged out of them into ſome convenient receptacle or emunctory.

EXCURSION, in aſtronomy, is uſed in a ſynonimous ſenſe with elongation. See ELONGATION.

EXECRATION, *execratio*, in antiquity, a kind of puniſhment, conſiſting of direful curſes and marks of infamy.

EXECUTION, in a general ſenſe, the act of accompliſhing, finiſhing, or atchieving any thing that is to be done.

EXECUTION, in law, the completing or finiſhing ſome act, as of judgment, deed, &c. and it uſually ſignifies the obtaining poſſeſſion of any thing recovered by judgment of law.

Military EXECUTION, the pillaging or plundering of a country by the enemy's army.

EXECUTOR, in law, a perſon appointed by another's laſt will and teſtament to have the execution of the ſame after his deceaſe, and the diſpoſing of the teſtator's goods and effects according to the intent of the will.

The law accounts an executor one perſon with the party whoſe executor he is; having all the advantages of action, and being ſubject to the ſame actions as the deceaſed.

Hence, as an executor derives his power wholly from the will, he may releaſe a debt, or do any thing as executor, before probate of the will, provided he afterwards proves it: however, to maintain actions for debts, he muſt ſhew the teſtament proved. He may immediately take the goods, or give power to another to ſeize them for him.

A perſon capable of making an executor, either makes one, two, three, or more; and he may appoint that one ſhall be his executor for one year, and another for another. If he appoints executors only for a certain number of years, after they are elapſed, the ordinary may grant adminiſtration of the goods; as he may do, till the power of executors take place. It is alſo obſervable, that where there is no executor, there is properly no will; and where there is no will there can be no executors; but this only regards goods; for where lands in fee are deviſed, it is a good will, though no executor be named therein.

An executor may either accept or refuſe the executorſhip; but after he has accepted the office, he ſhall not refuſe the ſame, nor take it up after refuſal. If any one of the ſeveral executors prove the will, it will ſerve for all; ſo that the reſt may at any time after join with him and intermeddle with the eſtate. When any action is brought, it muſt be in the name of all the executors, notwithſtanding ſome of them may not act; but in any action commenced againſt them, he only that adminiſters is to be ſued. The poſſeſſion of one executor is held to be poſſeſſion of them all; and moſt acts done by or to one, are deemed done by or to all of them.

EXECUTORY, in law, is where an eſtate in fee, that is made by deed or fine, is to be executed afterwards by entry, livery, or writ. Leaſes for years, annuities, conditions, &c. are termed inheritances executory.

EXECUTORY DEVISE, is when the fee by deviſe is veſted in any perſon, and is to be veſted in another upon contingency. In all caſes of executory deviſes, the eſtates deſcend until the contingencies happen.

EXEDRA, in church hiſtory, a name ſometimes given to the ambo. See the article AMBO.

EXEDRÆ, in antiquity, a general name for ſuch buildings as were diſtinct from the main body of the churches, and yet within the limits of the church taken in its largeſt ſenſe.

EXEMPLIFICATION OF LETTERS PATENT, a tranſcript or duplicate of them, made from the inrollment thereof, and ſealed with the great ſeal.

EXEMPTION, in law, a privilege to be free from ſome ſervice or appearance.

EXERCISE is ſuch an agitation of the body as produces ſalutary effects in the animal œconomy.

Exerciſe, Dr. Cheyne obſerves, is indiſpenſably neceſſary to preſerve the body in due plight; without exerciſe the juices will thicken, the nerves relax, the joints ſtiffen; and, on theſe diſorders, chronical diſeaſes and a crazy old age will enſue. The body may be conſidered as a ſyſtem of tubes and glands admirably adapted throughout, as a proper engine for the ſoul to work with. Exerciſe ferments the humours, caſts them into their proper channel, throws off redundancies, and helps nature in thoſe ſecret diſtributions without which the body cannot ſubſiſt in its vigour, nor the ſoul act with chearfulneſs. Had not exerciſe been abſolutely neceſſary for our well-being, nature would not have given ſuch an activity to the limbs of the body, and ſuch a pliancy to every part, as neceſſarily produce thoſe compreſſions, extenſions, dilatations, and all other kinds of motions neceſſary for the preſervation of ſuch a ſyſtem of tubes and glands. And, that we might not want inducements to ſuch an exerciſe of the body, riches and honour, even food and raiment, are not to be come at, without the toil of the hands, and ſweat of the brow.

He farther obſerves, that thoſe organs of the body which

which are moſt uſed, always become the ſtrongeſt. Thus the legs, feet, and thighs of chairmen, the arms and hands of watermen, the backs and ſhoulders of porters, grow thick and ſtrong by uſe. Of all the kinds of exerciſe there is none which conduces ſo much to the health, and is every way accommodated to the body, as that of riding, which is leſs laborious and expenſive of ſpirits than any other. Dr. Sydenham is very laviſh in its praiſes. Dr. Mead too recommends it in the concluſion of his *Monita & Præcepta*.

EXERCISE, in military affairs, is the ranging a body of ſoldiers in form of battle, and making them perform the ſeveral motions and military evolutions with different management of their arms, in order to make them expert therein.

EXERCISES are alſo underſtood of what young gentlemen learn in the academies and riding ſchools, ſuch as fencing, dancing, riding the great horſe, &c.

EXERGUM, among antiquarians, a little ſpace around or without the figures of a medal, left for the inſcription, cypher, device, date, &c.

EXFOLIATION, in ſurgery, the ſcaling of a bone, or its ſeparating into laminæ or leaves.

The word is Latin, *exfoliatio*, and derived from *ex*, and *folium*, a leaf.

EX GRAVI QUERELA, in law, is a writ that lies for the perſon to whom any lands or tenements in fee are deviſed by will, and the heir of the deviſor enters thereon, and detains them from the deviſee.

EXHALATION, in philoſophy, is applied to thoſe dry corpuſcles, as alſo to the pinguious, oleaginous, ſulphureous particles or effluvia, that are ſeparated from hard, earthly, fatty, bodies, particularly the earth itſelf, either by the heat of the ſun, the agitation of the air, or ſome other cauſes; and being emitted upwards, to a certain height in the atmoſphere, there mix with the vapours, which properly are thoſe moiſt fumes that are raiſed from water and other liquid bodies, and help to form clouds, which return back in dew, miſt, rain, ſnow, hail, &c.

The word is Latin, *exhalatio*, which is derived from *exhalo*, to breathe, or ſteam out.

The nitrous and ſulphureous exhalations are the chief matter of which thunder, lightning, dew, and other meteors are generated in the air. According to Sir Iſaac Newton, true and permanent air is formed from the exhalations raiſed from the hardeſt and moſt compact bodies.

EXHAUSTED RECEIVER, a glaſs, or other veſſel, out of which the air hath been drawn by means of the air-pump. See the article AIR-PUMP.

EXHAUSTIONS, in mathematics, is a method in frequent uſe among the ancient mathematicians, Euclid, Archimedes, &c. that proves the equality of two magnitudes, by a deduction ad abſurdum, in ſuppoſing that, if one be greater or leſs than the other, there would follow an abſurdity: this is founded on what Euclid ſays in his tenth book, namely, "That thoſe quantities whoſe difference is leſs than any aſſignable one, are equal;" for if they were unequal, be the difference never ſo ſmall, yet it may be ſo multiplied, as to become greater than either of them; if not ſo, then it is really nothing. This he aſſumes in the proof of the firſt propoſition of book ten, which is, "That if from the greater of two quantities you take more than its half, and from the remainder more than its half, and ſo continually, there will at length remain a quantity leſs than either of thoſe propoſed."

On this foundation they demonſtrate, that if a regular polygon of infinite ſides be inſcribed in, or circumſcribed about a circle, the ſpace that is the difference between the circle and the polygon will, by degrees, be quite exhauſted, and the circle be equal to the polygon.

EXHIBIT, in law, is where a deed, or other writing, being produced in a chancery ſuit, to be proved by witneſſes, the examiner, or commiſſioner appointed after the examination of any ſuch, certifies on the back of the deed, or writing, that the ſame was ſhewn to the witneſs, at the time of his examination, and by him ſworn to.

EXHIBITION, a benefaction ſettled for the benefit of ſcholars in the univerſities, that are not on the foundation.

EXHIBITION was anciently an allowance for meat and drink, ſuch as the religious appropriators made to the poor depending vicar.

EXHORTATION, in rhetoric, differs only from ſuaſion, as being more directly addreſſed to the paſſions.

EXIGENT, in law, a writ which lies where the defendant in a perſonal action cannot be found, nor any effects of his within the county, by which he may be attached or diſtrained.

EXIGENTERS, four officers in the court of Common-Pleas, who make all exigents and proclamations in all actions where proceſs of outlawry lies.

EXILIUM, in law, ſignifies a ſpoiling; but ſeems to be reſtrained to the injury done to tenants by altering their tenure, ejecting them, &c.

EXISTENCE, that whereby a thing has an actual eſſence, or is ſaid to exiſt, or be.

The word is Latin, and derived from *exiſto*, to be, or exiſt.

It has been a ſubject of great diſpute, whether eternal bodies have any exiſtence but in the mind; that is, whether they really exiſt, or exiſt in idea only. The former opinion is ſupported by Mr. Locke, and the latter by Dr. Berkeley.

Thoſe who deſire to ſee the arguments brought by thoſe learned authors, we refer to Locke's Eſſay on Human Underſtanding, and Berkeley's Princip. of Human Knowledge.

EXIT, *Exitus*, in law, properly ſignifies iſſue, or offſpring; but is alſo applied to iſſues, annual rents, and profits of lands.

EXIT, in a theatrical ſenſe, the action of a player in going off the ſtage, after he has played his part.

EXODIUM, in the ancient Greek drama, one of the four parts or diviſions of tragedy, being ſo much of the piece as included the cataſtrophe and unravelling of the plot, and anſwering nearly to our fourth and fifth acts. See EPILOGUE.

EXODIUM, ἔξοδιον, in the Septuagint, ſignifies the end or concluſion of a feaſt.

EXODUS, a canonical book of the Old Teſtament, being the ſecond of the Pentateuch, or five books of Moſes.

It is ſo called from the Greek ἔξοδος, going out, or departure of the children of Iſrael from the land of Egypt; the hiſtory of which is delivered in this book, together with the many miracles wrought on that occaſion.

EX OFFICIO, among lawyers, ſignifies the power a perſon has, by virtue of his office, to do certain acts without being applied to.

EXOMPHALUS, in ſurgery, is a hernia, or kind of rupture, that exhibits a preternatural tumor or protuberance at the navel.

The word is Greek, ἐξομφαλος, and derived from ἐξ, and ομφαλος, the navel.

This rupture is owing to a protruſion of the inteſtine, or omentum, or both of them, at the navel, and rarely happens to be the ſubject of an operation; for though the caſe is common, yet moſt of them are gradually formed from very ſmall beginnings, and if they do not return into the abdomen upon lying down, in all probability they adhere without any great inconvenience to the patient, until ſome time or other an inflammation falls upon the inteſtines, which ſoon brings on a mortification and death; unleſs, by great chance, the mortified part ſeparates from the ſound one, leaving its extremity to perform the office of an anus: in this emergency, however, I think it adviſable to attempt the reduction, if called in at the beginning, though the univerſal adheſion of the ſac and its contents are a great obſtacle to the ſucceſs: the inſtance in which it is moſt likely to anſwer, is, when the rupture is owing to any ſtrain, or ſudden jerk, and is attended with thoſe diſorders which follow upon the ſtrangulation of a gut.

In this caſe, having tried all other means in vain, the operation is abſolutely neceſſary; which may be thus performed: make the inciſion ſomewhat above the tumor, on the left ſide of the navel, through the membrana adi-

pósa; and then emptying the ſac of its water, or mortified omentum, dilate the ring with the ſame crooked knife, conducted on your finger; after this, return the inteſtines and omentum into the abdomen, and dreſs the wound without making any ligature, but of the ſkin only. *Sharp's Surgery.*

EXORCISM, a ceremony conſiſting of prayers and conjurations to drive the devil out of perſons poſſeſſed, or for the removal of any danger or diſeaſes from man or beaſt, and to deſtroy vermin and noxious animals.

The word is Greek, ἐξορκισμὸς, and derived from ἐξ, out of, and ὁρκὸς, an oath, or religious ceremony.

The uſe of exorciſm is almoſt as ancient as the church: it makes a conſiderable part of the ſuperſtition of the Romiſh church, for which ſhe hath appointed many ridiculous ceremonies in her rituals. The Romaniſts not only exorciſe demoniacs, but likewiſe houſes and other places which are haunted, as it is called; and this is done in the ſame manner as the exorciſm of perſons.

The ancient heathens practiſed exorciſms, but they were performed by the old women only, who, gadding from houſe to houſe, uſed to ſprinkle them with luſtral water, and lay the ſpirits by certain forms, ſome very whimſical and ridiculous ceremonies. The modern heathens of the Eaſt and Weſt Indies have alſo ſeveral ceremonies among them for caſting out devils and hobgoblins.

EXORDIUM, in rhetoric, is the introduction, preamble, or beginning of any diſcourſe, ſerving to prepare the audience for what is to follow.

The word is Latin; and derived from *ex*, out of, and *ordior*, to begin.

It is a fault into which the ancients have very often fallen, to make an exordium that has no relation to the ſubject in hand: in this the Greeks took more liberty than the Latins. The exordium ſhould be laboured with great care, whence Tully calls it *difficillima pars orationis*. It ſhould be ſimple, and free from too bold metaphors: the ſtile ſhould not be too much raiſed, nor ſhould it run into bombaſt. It was forbidden to make exordiums in the Areopagus at Athens, as it is an indirect and imperceptible manner of prepoſſeſſing the audience. There are two kinds of exordiums, the one juſt and formal, the other vehement and abrupt. In the firſt, the audience is prepared and conducted by due and eaſy ſteps; in the ſecond, the orator breaks out upon his audience at once, as if ſeized with ſome ſudden paſſion. Such is that exordium of Iſaiah, "Hear, O Heavens; and give ear, O Earth!" Abrupt exordiums are the moſt proper on occaſions of extraordinary joy, indignation, &c.

EXOSTOSIS is a preternatural excreſcence of a bone, as often happens in venereal caſes; or rather a protuberance cauſed by a bone's being out of its natural poſition.

The word is Greek, ἐξοστωσις, and derived from ἐξ, off, or out of, and ὀστεον, a bone.

EXOTIC is a term chiefly applied to plants which are foreign, and not of our own growth, particularly thoſe brought from the Eaſt and Weſt Indies: whence the uſe of hot-beds, green-houſes, &c. in order to make them thrive.

The word is Greek, ἐξωτικὸς, and derived from ἐξω, from without, or abroad.

Dr. Liſter, in the Philoſophical Tranſactions, gives an account of exotic diſeaſes, as 1. The plague, which is properly a diſeaſe of Aſia, where it is epidemic. 2. The ſmall-pox, not known in Europe, or even Aſia Minor, or Africa, till a ſpice trade was opened to the remoteſt parts of the Indies, where it rages more cruelly than among us. 3. The griping of the guts, which he takes to be peculiar to the Weſt-Indies, and yearly received from thence; which he ſays is quite different from the tormina ventris of the ancients, and is ſcarce ever known in the midland countries, or far in the north of England.

EXPANSION is the opening and ſtretching out of any body; but generally it ſignifies ſuch an alteration as is made by rarefaction, and the quantity of this Dr. Halley gives in the Philoſophical Tranſactions, N°. 197. The law of the expanſion of air is this, that the ſpaces into which air of a given quantity is compreſſed, are reciprocally proportionable to the compreſſing weights.

The word is Latin, *expanſio*, and derived from *ex*, out of, and *pando*, to ſtretch.

Dr. Gregory proves, in his Aſtronomy, that a globe of air, of but one inch in diameter, if it had ſo great an expanſion as it will have at a ſemi-diameter's diſtance of the earth from it, would fill all the planetary regions far beyond the ſphere of Saturn.

EX PARTE, a term uſed in the court of chancery, where a commiſſion is taken out and executed by one ſide or party only, upon the other party's neglecting or refuſing to join therein.

When both the parties proceed together, it is called a joint commiſſion.

EXPECTANT, in law, ſignifies having relation to, or depending on: thus, where land is given to a man and his wife, and to their heirs, they have a fee ſimple eſtate; but if it be given to them and the heirs of their bodies begotten, they have an eſtate tail, and a fee expectant, which is oppoſed to fee ſimple.

EXPECTORANTS, *Expectorantia*, in medicine, are ſuch things as promote a diſcharge of whatever is offenſive to the lungs and aſpera arteria.

The word is Latin, *expectorans*, and derived from *ex* and *pectus*, the breaſt.

EXPECTORATION, in medicine, is the act of evacuating or bringing up phlegm, or other matter, from the lungs, by coughing, ſpitting, &c.

The word is Latin, *expectoratio*, and derived from *ex* and *pectus*, the breaſt.

EXPEDITATION, in the foreſt law, is the cutting out the balls of dogs fore-feet, in order to preſerve the king's game.

The word is Latin *expeditatio*, and derived from *ex* and *pes*, a foot.

EXPENDITORS, the perſons who diſburſe or expend the money collected by the tax for repairs of ſewers, after the ſame is paid into their hands by the collectors, as ordered by the commiſſioners, and for which they are to render accounts when required.

EXPERIENCE, a kind of knowledge acquired by long uſe, without any teacher. Mr. Locke ſays, that men receive all the materials of knowledge from experience and obſervation. See the article IDEA.

Experience then conſiſts in the ideas of things we have ſeen or read, which the judgment has reflected on, to form itſelf a rule or method.

EXPERIMENT, in philoſophy, is the trial of the reſult or effect of the applications and motions of certain natural bodies, in order to diſcover ſomething of their motions and relations, whereby to aſcertain ſome of their phœnomena, or cauſes.

Torricellian EXPERIMENT. See the article TORRICELLIAN.

EXPERIMENTAL PHILOSOPHY, that philoſophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from ſenſible experiments and obſervations. The buſineſs of experimental philoſophy is to enquire into and to inveſtigate the reaſons and cauſes of the various appearances or phœnomena of nature, and to make the truth or probability thereof obvious and evident to the ſenſes, by plain, undeniable, and adequate experiments, repreſenting the ſeveral parts of the grand machinery and agency of nature.

In our enquiries into nature, we are to be conducted by thoſe rules and maxims which are found to be genuine, and conſonant to a juſt method of phyſical reaſoning; and theſe rules of philoſophizing are by the greateſt maſter in ſcience, ſir Iſaac Newton, reckoned four, which are as follows:

1. More cauſes of natural things are not to be admitted, than are both true, and ſufficient to explain the phœnomena; for nature does nothing in vain, but is ſimple, and delights not in ſuperfluous cauſes of things.

2. And, therefore, of natural effects of the ſame kind, the ſame cauſes are to be aſſigned, as far as it can be done: as of reſpiration in man and beaſts, of the deſcent of ſtones in Europe and America, of light in a culinary fire and in the ſun, and of the reflection of light in the earth and in the planets.

3. The qualities of natural bodies which cannot be increaſed

creaſed or diminiſhed, and agree to all bodies in which experiments can be made, are to be reckoned as the qualities of all bodies whatſoever: thus, becauſe extenſion, diviſibility, hardneſs, impenetrability, mobility, the vis inertiæ, and gravity, are found in all bodies which fall under our cognizance or inſpection, we may juſtly conclude they belong to all bodies whatſoever, and are therefore to be eſteemed the original and univerſal properties of all natural bodies.

4. In experimental philoſophy, propoſitions collected from the phœnomena by induction, are to be deemed (notwithſtanding contrary hypotheſes) either exactly or very nearly true, till other phœnomena occur, by which they may be rendered either more accurate, or liable to exception. This ought to be done, leſt arguments of induction ſhould be deſtroyed by hypotheſes.

Theſe four rules of philoſophizing are premiſed by Sir Iſaac Newton to his third book of the Principia; and more particularly explained by him in his Optics, where he exhibits the method of proceeding in philoſophy, the firſt part of which is as follows.

As in mathematics, ſo in natural hiſtory, the inveſtigation of difficult things, by way of analyſis, ought always to precede the method of compoſition. This analyſis conſiſts in making experiments and obſervations, and in drawing general concluſions from them by induction (i. e. reaſoning from the analogy of things by natural conſequence) and admitting no objections againſt the concluſions, but what are taken from experiments or certain truths: and although the arguing from experiments and obſervation, by induction, be no demonſtration of general concluſions, yet it is the beſt way of arguing which the nature of things admits of, and may be looked on as ſo much the ſtronger, by how much the induction is more general; and if no exception occur from phœnomena, the concluſion may be pronounced generally; but if at any time afterwards, any exception ſhall occur from experiments, it may then be pronounced with ſuch exceptions: by this way of analyſis we may proceed from compounds to ingredients, and from motions to the cauſes producing them; and, in general, from effects to their cauſes; and from particular cauſes to more general ones, till the argument ends in the moſt general: this is the method of analyſis: and that of ſyntheſis, or compoſition, conſiſts in aſſuming cauſes, diſcovered and eſtabliſhed as principles, and by them explaining the phœnomena proceeding from them, and proving the explanations.

EXPERIMENTUM CRUCIS, a capital, leading, or deciſive experiment; thus termed, either on account of its being like a croſs, or direction poſt, placed in the meeting of ſeveral roads, guiding men to the true knowlege of the nature of that thing they are enquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is as it were extorted by force.

EXPIATION, a religious act, by which ſatisfaction, atonement, or amends is made for the commiſſion of ſome crime, the guilt done away, and the obligation to puniſhment cancelled.

Great Day of EXPIATION, an annual ſolemnity of the Jews, upon the tenth day of the month Tiſri, which anſwers to our September.

EXPIATION, in a figurative ſenſe, is applied by divines to the pardons procured to mens ſins, by the merits of Chriſt's death.

EXPIRATION, in phyſic, that part of reſpiration whereby the air is expelled, or driven out of the lungs. See RESPIRATION.

EXPIRATION is alſo uſed for the end of any term agreed upon. It likewiſe ſignifies death.

EXPLOSION is properly applied to the going off of gunpowder, and the report made thereby; but it is frequently uſed to expreſs ſuch ſudden actions of bodies as have ſome reſemblance thereto; ſuch as the ſudden effervеſcence, ebullition, and expanſion that ariſe from the mixture of ſome contrary liquors; as ſpirit of nitre and ſpirit of wine; oil of vitriol and oil of turpentine; oil of vitriol and ſal ammoniac, &c

The word is Latin, *exploſio*, and derived from *explodo*, to drive out.

EXPONENT, in algebra, is a number placed over any power, or involved quantity, to ſhew to what height the root is raiſed, in order to contract the work. Thus, $x^4 = xxxx$. Here 4 is the exponent of the power x, and ſhews that it is involved to the fourth power.

The word is derived from the Latin *expono*, to ſhew, or expound.

EXPONENT *of a Ratio* is the quotient ariſing from the diviſion of the antecedent by the conſequent.

Thus the ratio of 3 to 3 is $1\frac{1}{1}$, and the ratio of 2 to 3 is $\frac{2}{3}$. If the conſequent be unity, the antecedent itſelf is the exponent of the ratio: and, therefore, the exponent of a ratio is to unity, as the antecedent is to the conſequent.

Though the quotient, reſulting from the diviſion of the antecedent by the conſequent, is generally taken for the exponent of the ratio; yet, in reality, the exponent of a ratio ought to be a logarithm. And this ſeems to be more agreeable to Euclid's definition of duplicate and triplicate ratios, than quotients: for 1, 3, and 9, are continual proportionals; now, if $\frac{1}{3}$ be the exponent of the ratio of 1 to 3, and $\frac{1}{9}$, or $\frac{1}{3^2}$, the exponent of the ratio of 3 to 9, and $\frac{1}{2}$ the exponent of the ratio of 1 to 9; and ſince Euclid ſays, "If three quantities are proportional, the ratio of the firſt to the third is ſaid to be the duplicate of the ratio of the firſt to the ſecond, and of the ſecond to the third;" therefore $\frac{1}{2}$ muſt be the double of $\frac{1}{3}$, which is very falſe. But the logarithm of the ratio of 1 to 9, that is, the logarithm of 9 is the double of the ratio of 1 to 3, or 3 to 9, that is, the logarithm of 3. From whence it appears, that logarithms are more properly the exponents of ratios, than numerical quotients; and of this opinion ſeem Dr. Halley, Mr. Cotes, and others.

EXPONENT, in arithmetic, is uſed in the ſame ſenſe as index or logarithm. See INDEX and LOGARITHM.

EXPONENTIAL CALCULUS, the manner of finding the fluxions, and of ſumming up the fluxions of exponential quantities.

The fluxions of exponential quantities may be readily and eaſily found by the help of the logarithmic ſeries; and, in order to this, it is neceſſary to premiſe, that the fluxion of any logarithm is equal to the fluxion of the abſolute number or quantity whoſe logarithm it is, divided by the ſame number. Thus, if $x+1$ repreſent any given quantity, the fluxion of the logarithm of this quantity will be $\frac{\dot{x}}{x+1}$. And the fluxion of the logarithm of $xx+yy$, which is expreſſed after this manner, $\dot{L} : xx+yy$, is $\frac{2x\dot{x}+2y\dot{y}}{xx+yy}$. And by the ſame method may the fluxion to the logarithm of any power of a given quantity be determined.

Therefore the fluxions of the logarithms of any powers of the ſame quantity are to one another, as the exponents of thoſe powers: that is, $\dot{L} : 1+x : \dot{L} : 1+x :: 1 : n$. For $\dot{L} : 1+x = \frac{\dot{x}}{1+x}$, and $\dot{L} : 1+x = \frac{n\dot{x}}{1+x}$. But as $\frac{\dot{x}}{1+x} : \frac{n\dot{x}}{1+x} :: 1 : n$.

Hence we are taught how to find the fluxion of exponential quantities, in the following manner:

Let it be required to find the fluxion of a^x, where a is ſuppoſed to be a conſtant quantity.—Put $a^x = y$, then will $\dot{y}$ be equal to the fluxion of a^x; and, becauſe $a^x = y$, therefore $\dot{L} : a^x = \dot{L} : y$; wherefore $\dot{x}\dot{L} : a = \dot{L} : y$, and conſequently $\dot{x}\dot{L} : a + \dot{x}\dot{L} : a = \dot{L} : y$; but $\dot{L} : a = \frac{\dot{a}}{x} = 1$, becauſe the quantity a is a conſtant quantity, and therefore its fluxion nothing: and $\dot{L} : y = \frac{\dot{y}}{y}$; therefore $\dot{x}\dot{L} : a = \frac{\dot{y}}{y}$; and $y\dot{L} : a\dot{x} = \dot{y} = a^x$, and conſequently $a^x \dot{L} : a\dot{x}$, is the fluxion of a^x required.

EXPONENTIAL CURVE is that whoſe nature is expreſſed by an exponential equation.

EXPONENTIAL EQUATION is that wherein there is an exponential quantity, $a^x = y$.

EXPONENTIAL QUANTITY is a quantity whoſe power or exponent is a variable or flowing quantity.

Exponential quantities are of ſeveral powers or degrees, according as the exponents themſelves are more or leſs involved. If the exponent be a ſimple quantity, as z^y, it is called an exponential of the firſt or loweſt degree; but when the exponent itſelf is an exponential of the firſt degree, as z^{y^x}, it is called an exponential of the ſecond degree. In like manner, if the exponential itſelf be an exponential of the ſecond degree, as $z^{y^{x^o}}$, it is called an exponential of the third degree, &c.

EXPORTATION, the ſhipping and carrying out of the kingdom wares and commodities for other countries.

Exportation is part of foreign commerce, diſtinguiſhed by the appellation active or ſelling part, in oppoſition to importation, which is called the paſſive, or buying part. Belloni obſerves, that commerce, when active, muſt produce a vaſt flow of riches, the balance being always received in money; whereas, if it be paſſive, the moſt immenſe treaſures will be ſoon exhauſted, as the balance of trade muſt be continually made good out of the remaining coin. Hence, plenty of money in any place, implies, that the quantity of goods exported far exceeds that of goods imported; and wherever we ſee money ſcarce, we may conclude that greater quantities of goods have been imported than exported. See the articles COMMERCE, MONEY, and EXCHANGE.

EXPOSITOR, or EXPOSITORY, a title given to ſmall dictionaries, ſerving to explain the hard words of a language.

EX POST FACTO, in law, ſomething done after another: thus, an eſtate granted may be good by matter ex poſt facto, that was not ſo at firſt, as in caſe of election.

EXPOSTULATION, in rhetoric, a warm addreſs to a perſon, who has done another an injury, repreſenting the wrong in the ſtrongeſt terms, and demanding redreſs.

EXPOSURE, or EXPOSITION, in gardening, is the aſpect or ſituation of a garden, or wall, with reſpect to the ſun or winds: they are, therefore, as various as the points of the compaſs; being either direct, as eaſt, weſt, north, or ſouth; or declining, as ſouth-eaſt, north-weſt, &c. The gardeners do not give thoſe names to the places where the ſun is, but to thoſe whereon he ſhines. A wall ſtanding to the north, and facing the ſouth, is ſaid to have a ſouth aſpect or expoſure: and a wall which faces the riſing ſun is ſaid to have an eaſtern expoſure; and ſo of the others. If the ſun at his riſing, and during the firſt half of the day, continue to ſhine upon one ſide of a garden or wall, that is an eaſtern expoſure: that ſide which the ſun ſhines upon the latter half part of the day has a weſtern expoſure. That part where it ſhines longeſt in the day, from nine till four, is the ſouth aſpect; and that part on which it ſhines leaſt, has a north expoſure.

The eaſtern and ſouthern expoſures are, by common conſent of all gardeners, the two principal, and have a conſiderable advantage above the reſt. The eaſtern, commencing differently at different ſeaſons of the year, and ending about noon, ſubjects the trees, &c. to the north-eaſt winds, which wither the leaves, blow down the fruit, &c. Yet Mr. Laurence judges the eaſt better than the weſt wall for all kinds of fruit, becauſe the early rays of the ſun ſooner take off the cold chilly dews of the night. The weſtern, accounted half an hour after eleven till ſun-ſet, is more backward than an eaſtern one by eight or ten days; but it has this advantage, that it receives little damage from the froſts, which melt before the ſun comes to ſhine upon the fruit, and fall off like dew without doing any prejudice: but it is incommoded with the north-weſt winds in the ſpring, as alſo with the autumnal winds, which blow down a deal of fruit. The weſtern expoſure is better than the north, which is the worſt of all.

EXPRESSED OILS, in chemiſtry, are ſuch as are obtained from bodies only by preſſing.

EXPRESSION, in chemiſtry, or pharmacy, denotes the act of preſſing out the juices, or oils of vegetables, which is one of the three ways of obtaining them; the other two are by infuſion and decoction. Oils obtained by means of fire are called ſtillatitious.

EXPRESSION, in rhetoric, is the elocution, diction, or choice of words neceſſary to render any diſcourſe eloquent.

As the principal end of ſpeaking is to be underſtood, the firſt thing we ſhould endeavour to obtain is a richneſs of expreſſion, or habit of ſpeaking ſo well, that our thoughts may be underſtood. As we are ſurrounded from our cradle by ignorant and vulgar people, who ſcarce know their mother-tongue, we are forced to ſtudy for that which nature ought to have taught us. It is much eaſier to imitate the ſublimity of Seneca or Lucan, than the unaffected ſimplicity of Terence. Thoſe that are capable of writing like Terence, may reach Lucan's grandeur if they pleaſe; but a man who has always uſed himſelf to the ſwelling ſtile, will never imitate Terence happily. Of this opinion is Cicero, and alſo Horace, who, in ſpeaking of the natural ſtile of converſation, ſays, "I will make verſes compoſed of known expreſſions, ſo that in reading them, every one ſhall hope to do the like." So much force is there in order and connexion, and ſo much elegance in ſtile taken from the common language, compoſed only of pure and proper expreſſions. In ſhort, beautiful expreſſion is the natural and true light of our thoughts; it is to this we owe all thoſe excellencies in diſcourſe, which give things a kind of vocal life and ſpirit.

EXPRESSION, in painting, is the repreſentation of an object according to its natural character and the painter's invention or plan.

In portraits it muſt be ſeen whether the perſon is grave, gay, a man of buſineſs or wit, plain, gentle, &c. each character muſt have an attitude, the ornaments, and back-ground proper to it; and all about it muſt be expreſſive of the man, and have a reſemblance as well as the features of the face.

If the perſon has any particularities as to the poſition of the head, eyes, or mouth, if not unbecoming, they muſt be ſtrongly expreſſed. Theſe are a ſort of moving features, and are as much a part of the man as the fixed ones; ſome things raiſe a low ſubject, and contribute more to a ſurpriſing likeneſs than any thing elſe. Van Dyck in a picture has given a briſk touch upon the under-lip, which makes the poſition of the mouth very particular, and doubtleſs was an air which don Diego de Guſman, whoſe portrait it is, was accuſtomed to give himſelf, which an inferior painter would not have obſerved, or not dared to have marked, at leaſt ſo ſtrongly; but this, as it gives a marvellous ſpirit and ſmartneſs, undoubtedly gave a proportionate reſemblance.

If there be any thing particular in the hiſtory of the perſon which is proper to be expreſſed, it is a great improvement to the portrait, to them that know that circumſtance. There is one inſtance of this in a picture Van Dyck made of John Lyvens, who is drawn as if liſtening to ſomething; which refers to a remarkable ſtory in that man's life. The print is in the book of Van Dyck's heads; which book, and the heads of the artiſts in the lives of Giorgio Vaſari, are worth conſidering, with regard to the variety of attitudes, as well as upon other accounts.

Robes, or other marks of dignity, or of a profeſſion, employment, or amuſement, a book, a ſhip, a favourite dog, or the like, are hiſtorical expreſſions common in portraits.

There are ſeveral kinds of artificial expreſſions practiſed by painters, becauſe of the diſadvantage of their art in that particular, in compariſon of words.

To expreſs the ſenſe of the wrath of God with which our Bleſſed Lord's mind was filled when in his agony, and the apprehenſion he was then in of his own approaching crucifixion, Frederico Barocci has drawn him not only with the angel holding the cup to him, but in the back-ground you ſee the croſs and flames of fire.

In the cartoon where the people of Lycaonia are going to ſacrifice to St. Paul and Barnabas, the occaſion of all that is finely expreſſed.

The man who was healed of his lameneſs is one of the forwardeſt to expreſs his ſenſe of the divine power which appeared in thoſe apoſtles; and not only a crutch

is under his feet on the ground, but an old man takes up the lappet of his garment, and looks upon the limb which he remembered to have been crippled, and expreſſes great devotion and admiration; which ſentiments are alſo ſeen in others with a mixture of joy. When our Saviour committed the care of his church to St. Peter, the words he uſed on that occaſion are related by Raphael, who has made him pointing to a flock of ſheep, and St. Peter to have juſt received two keys. When the ſtory of Joſeph's interpretation of Pharaoh's dream was to be related, Raphael has painted thoſe dreams in two circles over the figures; which he has alſo done, when Joſeph relates his own to his brethren. His manner of expreſſing God's dividing the light from darkneſs, and the creation of the ſun and moon, is altogether ſublime. The prints of thoſe laſt mentioned pictures are to be found in Raphael's bible, but the paintings are in the Vatican.

The hyperbolical artifice of Timanthes to expreſs the vaſtneſs of the Cyclops is well known, and was greatly admired by the ancients; he made ſeveral ſatyrs about him as he was aſleep; ſome were running away as frighted, others gazing at a diſtance, and one was meaſuring his thumb with his thyrſus, but ſeeming to do it with great caution, leſt he ſhould awake.

This expreſſion was copied by Giulio Romano with very little variation. Correggio, in his picture of Danae, has finely expreſſed the ſenſe of that ſtory; for, upon falling of the golden ſhower, Cupid draws off her linen-covering, and two lovers are trying upon a touch-ſtone a dart tipped with gold.

Nicholas Pouſſin expreſſes a voice, in the baptiſm of our Saviour, by making the people look up, and about, as it is natural when men hear any ſuch, and know not whence it comes, eſpecially if it be otherwiſe extraordinary, as in this caſe.

Another way practiſed by painters to expreſs what could not otherwiſe be done, is by figures repreſentative of certain things. This they learned from the ancients, examples of which we have in the Antonine pillar, where to expreſs the rain that fell, when the Roman army was preſerved by the prayers of the Theban legion, the figure of Jupiter Pluvius is introduced. Raphael, in the paſſage of Jordan, has repreſented that river by an old man dividing the waters, which are rolled and tumbled very remarkably.

The true airs of the heads of that great maſter Raphael are only to be found in what his own inimitable hand has executed, of which there are many originals in ſeveral collections in England; particularly in thoſe of the duke of Devonſhire and the earl of Pembroke; but the queen's palace is now the great ſchool of Raphael.

Beſides him none of the old maſters are remarkable for expreſſion, unleſs for particular ſubjects; as Michael Angelo for infernal, or terrible airs; and amongſt others, the drawing he made for the cartoon in his Laſt Judgment, is admirable in this kind; others in later times have ſucceeded well in this part of the art, particularly Domenichi and Rembrandt; and herein, next to Raphael, perhaps no man has a better title to the preference than Van Dyck; no not Titian himſelf, much leſs Rubens.

But there is no better ſchool than nature for expreſſion. A painter therefore ſhould, on all occaſions, obſerve how men look and act, when pleaſed, grieved, angry, &c.

Love is expreſſed by a clear, fair, and pleaſant countenance, without clouds, wrinkles, or unpleaſant bendings; giving the forehead an ample height and breadth, with a majeſtic grace; a full eye, with a fine ſhadow at the bottom of the eye-lid, and a little at the corner; a proportionable noſe; noſtrils not too wide; a clear cheek, made by ſhadowing it on one ſide; and a ſmiling mouth, made by a thin upper-lip, and ſhadowing the mouth-line at the corners.

Fear is expreſſed by making the eyes look hollow, heavy, and downwards, thin fallen cheeks, a cloſe mouth, and careleſs ſtaring hair about the ears.

Envy is beſt expreſſed by only the hanging of the cheeks, and a pale countenance; and ſometimes by grinding of the teeth.

Let every paſſion be repreſented according to its outward appearance in thoſe in whom it reigns.

If you aim at any exquiſiteneſs in this art, you muſt endeavour to chooſe out the beſt actions for every purpoſe, in reſtraining the luxurious fancy of nature by a deliberate diſcretion, by the benefit of which you will finiſh your deſign; always expreſſing in each member a certain hidden reſemblance of the principal motions which affect the eye and ſoul of the ſpectators.

To expreſs a paſſion truly, you ought to give every thing its proper motion, or that which beſt ſuits your intention; which is nothing elſe but the agreement of proportion with the action or paſſion intended, wherein conſiſts the whole life of the art, for hereby an evident difference is made between the living and the dead; the fierce and the gentle; the wiſe and the ſimple; the ſad and the merry: and in a word, diſcovers all the ſeveral paſſions and geſtures which the body of a man is capable of.

But before theſe things can be exactly done in a picture, you muſt firſt intenſely conſider the life, that you may come as near it as poſſible; to which adding art, you will meet with no motions ſo potent, which you will not be able artificially to imitate.

Theſe things will be the more exactly accompliſhed, by viewing and continually practiſing what you have ſeen; ſo as lively to expreſs all geſtures, actions, and paſſions, incident to natural bodies.

EXTASY, a tranſport which ſuſpends the function of the ſenſes, by the intenſe contemplation of ſome extraordinary or ſupernatural object, or when God impreſſes on the imagination the extraordinary ideas of any thing he would reveal.

EXTENSION, in philoſophy, is the quality or property of any thing extended that occupies ſpace. The eſſence of body or quality conſiſts in extenſion, of which there are three ſorts, length, breadth, and depth.

The word is Latin, *extenſio*, and derived from *ex*, and *tendo*, to ſtretch out, or extend.

EXTENSOR, an appellation given to ſeveral muſcles, from their extending or ſtretching the parts to which they belong: ſuch are, 1. The common extenſor of the fingers, which has its origin at the external condyle of the humerus, and the poſterior part of the radius and ulna: it afterwards divides into four tendons, which paſs under the ligament of the carpus, and terminate in the poſterior ſurface of all the phalanges of the fingers, where they are gibbous. 2. The extenſor of the thumb, called alſo bicornis and tricornis, ariſes in the poſterior and middle part of the radius and ulna, and terminates in two or three tendons in the firſt, ſecond, and third phalanx of the thumb. 3. The proper extenſors of each finger, which are a part of it, or at leaſt have their origin with the common extenſor. 4. The long extenſor of the toes, which has its origin in the upper part of the tibia, and in the anterior part of the ligament, between the tibia and fibula: it afterwards divides into five tendons, four of which are inſerted into the four phalanges of the toes, and the fifth into the outer metatarſal bone. 5. The ſhort extenſor of the toes ariſes from the upper part of the calcaneum, and dividing into tendons, is inſerted into the toes.

Beſides theſe, there are proper extenſors of the toes; alſo the long and ſhort extenſors of the great toe, and the common extenſor of the back and loins, which is divided into three. If theſe act only on one ſide, they draw the parts obliquely ſideways.

EXTENT, in law, is uſed in a double ſenſe; ſometimes it ſignifies a writ or command to the ſheriff for the valuing of lands or tenements; and ſometimes the act of the ſheriff, or other commiſſioner, upon this writ: but moſt commonly it denotes an eſtimate or valuation of lands; and hence come our extended or rack-rents.

EXTERMINATION *of Quantities*, in algebra. See EQUATION.

EXTERNAL *Angles* are the angles on the outſide of any right lined figure, when all the ſides are ſeverally produced, and they are all, taken together, equal to four right angles. See the article ANGLE.

EXTINGUISHMENT, in law, is a conſolidation

or union, as where one has due to him a yearly rent out of lands, and afterwards purchaſes the lands out of which the rent ariſes; in this caſe, both the property and the rent being united in one poſſeſſor, the rent is ſaid to be extinguiſhed. Likewiſe, where a perſon has a leaſe for years, and he afterwards buys the property of what is leaſed, the leaſe becomes thereby extinguiſhed.

EXTORTION, in law, is an illegal manner of wreſting any thing from a man either by force, menace, or authority. It is alſo the exaction of unlawful uſury, winning by unlawful games, and taking more than is due under pretence of right, as exceſſive tolls in millers, &c.

EXTRA-JUDICIAL is when judgment is given in any cauſe that is not depending in that court where ſuch judgment is given, or wherein the judge has no juriſdiction.

EXTRACT, in pharmacy, is the purer part of vegetables, or other natural bodies, that has been ſeparated from the more groſs parts, and diſſolved in ſome proper menſtruum by means of digeſtion, and reduced to a thick and moiſt conſiſtence, by diſtillation or evaporation of the menſtruum.

EXTRACT, in matters of literature, is ſomething copied or collected from a book or paper.

EXTRACTION, in chemiſtry, the operation whereby eſſences, tinctures, &c. are extracted, or drawn from natural bodies.

EXTRACTION, in ſurgery, ſignifies the extracting any foreign matter out of the body, by the help of inſtruments.

EXTRACTION *of Roots*, the method of finding the root of given numbers or quantities. See ROOT.

The ſquare, cube, and other powers of a number, or root, are formed by multiplying the given number into itſelf a greater or leſs number of times, as the power required is higher or lower. See POWER.

This multiplication compounds the powers; and the extraction of the root decompounds them again, or reduces them to their firſt principles or roots. So that the extraction of the root is to the multiplication of the power, what the analyſis is to the ſyntheſis.

Thus, 4 multiplied by 4, produces 16, which is the ſquare of 4; and 16 multiplied by 4, makes 64, which is the cube of 4:—Such is the compoſition of powers.

Again, the ſquare root of 16 is 4, by reaſon 4 is the quotient of 16 divided by 4; and the cube root of 64 is likewiſe 4, by reaſon 4 is the quotient of 64 divided by the ſquare of 4:—Such is the extraction of roots.

Hence to extract the root out of a given power is the ſame thing as to find a number; E. gr. 4, which being multiplied a certain number of times into itſelf, produces the given power, e. gr. 16, or 64.

For the extraction of ſquare and cube roots, it is neceſſary to have the ſquares and cubes of all the digits in readineſs, as exhibited in the following table.

Roots.	1	2	3	4	5	6	7	8	9
Squares	1	4	9	16	25	36	49	64	81
Cubes.	1	8	27	64	125	216	343	512	729

To extract the ſquare root out of a given number.—1°. Divide the given number into claſſes, of two figures apiece; and include each claſs between two dots, commencing with the place of units, or the right hand figure: the root will conſiſt of ſo many parts or figures as you have claſſes.—By the way obſerve, it may happen that for the laſt claſs on the left hand there ſhall only be one figure left.

2°. Then the left hand claſs being the ſquare of the firſt figure of the root ſought, look in the table of roots for the ſquare roots anſwering to that number; or if that ſquare number be not preciſely there, to the next leſs number: this root write down for the firſt figure of the quotient, and ſubtract its ſquare from the left hand claſs.—To the remainder bring down the next claſs towards the right.

3°. Write down the double of the quotient figure under the left hand of the ſecond claſs, and ſeek how often this decuple is contained in the figure over it; the quotient gives the ſecond figure of the root.

4°. Write the ſame quotient under the right hand figure of the ſame claſs, and ſubtract the product of the whole number underwritten, multiplied by the firſt figure of the root, from the number over it, as in diviſion.

5°. This operation being repeated according to the third and fourth ſteps, i. e. the remainder being ſtill divided by the double of the root, as far as extracted; and from the remainder, the ſquare of the figure that laſt came out, with the decuple of the aforeſaid diviſor augmented thereby, being ſubtracted; you will have the root required.

Example. To extract the ſquare root of 99856. Point it after the following manner, 99856: then ſeek a number whoſe ſquare ſhall be equal to the firſt figure 9, viz. 3, and write it in the quotient; then having ſubtracted from 9, 3×3, or 9, there will remain 0; to which ſet down the figures as far as the next point, viz. 98, for the following operation.

Then taking no notice of the laſt figure 8, ſay, How many times is the double of 3 or 6, contained in the firſt figure 9? Anſwer, 1. Wherefore, having written 1 in the quotient, ſubtract the product of 1×61, or 61 from 98, and there will remain 37, to which connect the laſt figures 56, and you will have the number 3756, in which the work is next to be carried on; wherefore alſo, neglecting the laſt figure of this, viz. 6, ſay, How often is the double of 31, or 62, contained in 375 (which may be gueſſed at from the initial figures 6 and 37, by taking notice how many times 6 is contained in 37)? Anſwer, 6; and writing 6 in the quotient, ſubtract 6×626, or 3756, and there will remain ●; whence it appears, that the buſineſs is done, the root coming out 316.

```
99856 (316
 9
 ---
 098
  61
 ---
 3756
 3756
 ....
```

Otherwiſe, with the diviſors ſet down, it will ſtand thus:

```
99856 (316
 9
---
6) 098
    61
   ---
62) 3756
    3756
    ....
```

Again, if you were to extract the root out of 22178791: Firſt, having pointed it, ſeek a number, whoſe ſquare (if it cannot be exactly equalled) ſhall be the next leſs ſquare (or neareſt) to 22, the figures to the firſt point, and you will find it to be 4: for 5×5, or 25, is greater than 22, and 4×4 or 16, is leſs; wherefore 4 will be the firſt figure of the root. This therefore being writ in the quotient, from 22 take the ſquare 4×4, or 16, and to the remainder 6, adjoin the next figure 17, and you will have 617; from whoſe diviſion, by the double of 4, you are to obtain the ſecond figure of the root, viz. 7, as thus; neglecting the laſt figure 7, ſay, How many times 8 is contained in 61? Anſwer, 7; wherefore write 7 in the quotient, and from 617 take the product of 7 into 87 or 609, and there will remain 8; to which join the two next figures 87, and you will have 887; by the diviſion whereof by the double of 47, or 94, you are to obtain the third figure; in order to which ſay, How many times is 94 contained in 88? Anſwer, 0: wherefore write 0 in the quotient, and adjoin the two laſt figures 91, and you will have 88791, by whoſe diviſion by the double of 470, or 940, you are to obtain the laſt figure; thus, I ſay, How many times 940 in 8879? Anſwer, 9: wherefore write 9 in the quotient, and you will have the root 4709.

```
. . . .
22178791 (4709,43637, &c.
16
---
617
609

 282566169
 ---------
  73624231
```

But ſince the product 9×9409, or 84681, ſubtracted from 88791, leaves 4110, the number 4709 is not the root of the number 22178791 preciſely, but a little leſs.

If then it be required to have the root approach nearer, carry on the operation in decimals, by adding to the remainder two cyphers in each operation. Thus the remainder 4110 having two cyphers added to it, becomes 411000; the diviſion whereof by the double of 4709, or 9418, you will have the firſt decimal figure 4. Then having writ 4 in the quotient, ſubtract 4×94184, or 376736, from 411000, and there will remain 34264. And ſo having added two more cyphers, the work may be carried on with pleaſure, the root at length coming out 4709,43637, &c.

But when the root is carried half-way or above, the reſt of the figures may be obtained by diviſion alone; as in this example, if you had a mind to extract the root to nine figures, after the five former 4709,4 are extracted, the four latter may be had, by dividing the remainder, viz. 342640, by the double of 4709,4.

After the ſame manner are roots extracted out of decimal numbers.—Thus, the root of 329,76 is 18,159; and the root of 3,2976 is 1,8159; and the root of 0,032976 is 0,18159, and ſo on. But the root of 3297,6 is 57,4247; and the root of 32,976 is 5,74247. And thus the root of 9,9856 is 3,16.

EXTRACTION *of the Cube Root* may be performed by the following method, which admits of two caſes.

Having pointed the number to be extracted, generally called the reſolvend, into claſſes of three figures a-piece, ſeek a cube number that comes the neareſt to the firſt period of the reſolvend, whether it be greater or leſs than that period.

Caſe 1. If the cube number ſo taken be leſs than the firſt period of the reſolvend, call its root leſs than juſt, and ſubtract that cube from the firſt period of the reſolvend.

Caſe 2. But if the cube be greater than the firſt period of the reſolvend, call its root more than juſt, and ſubtract the reſolvend from that cube, annexing cyphers to it.

To the firſt root, whether it be leſs or more than juſt, annex ſo many cyphers as there are remaining points over the whole number of the reſolvend, and multiply it by 3; then make the product a diviſor, by which you muſt divide the difference between the reſolvend and the foreſaid cube, then will that quotient be the reſolvend depreſſed to a ſquare; and therefore it muſt be pointed as ſuch, viz. into periods of two figures each. That being done, make the firſt root (without theſe cyphers that were annexed to it) a diviſor, enquiring how often it may be found in the firſt period of the new reſolvend (as before in extracting the ſquare root) with this conſideration, that if the root (now a diviſor) be leſs than juſt, you muſt annex the quotient figure to it; and then multiply the root ſo increaſed into the ſaid quotient figure; ſetting down the units place of their product under the pointed figure of that period, and ſubtracting it as in diviſion: and ſo on from one period to another as before. But if the ſaid root, now a diviſor, be more than juſt, then you muſt ſubtract the quotient figure from cyphers annexed, or ſuppoſed to be annexed to the ſaid diviſor, multiplying the root ſo reduced into the quotient figure, ſetting down their product as before, &c. An example or two will make the work plain and eaſy.

Example 1.

What is the cube-root of 146363183, the given reſolvend, to be pointed thus:

146363183 (5 the firſt root, leſs than juſt.
125 = the neareſt cube to 146.

500×3=1500) 21363183 (14242,12 new reſolvend.
1ſt. Div. 5) 14242,12 (527 the root required.
+ 2 104
2d. Div. 52) 3842
+ 7 3689
Root 527 (153) the remainder to be rejected.

Here the root 527 is the true root at the firſt operation, as may be eaſily tried from involving it.

That is, 527×527×527=146363183, the given reſolvend. But if it had not been the true root, then every thing that hath been here done muſt have been repeated, only inſtead of the firſt ſingle root (viz. 5) you muſt have taken the increaſed root, viz. 527; and this I call a ſecond operation, which would increaſe the laſt root to nine places of figures, viz. every operation triples the number of places in the laſt root.

N. B. It often happens that four and ſometimes five places of figures may be taken into the root, eſpecially when the ſecond place proves to be a cypher; that is, when the firſt cube comes very near to the firſt period of the reſolvend.

Example 2.

What is the c. rt. of 67507824239 (4000 root leſs than juſt.
Firſt neareſt cube = 64
Rt. 4000×3=12000) 3507824239 (292318,68
4)
+ 0 292318,68 (4071,8
1. Diviſor 40 2923
+ 7 2849
2. Diviſor 407) 7418
+ 1 4071
3. Diviſor 4071) 3347,68
+ ,8 3257,44, &c.
Root = 4071,8

In this example five figures are taken into the root, becauſe the ſecond place proved to be a cypher. And in theſe five the exceſs is not an unit in the laſt place; for if there were made a ſecond operation, the root would be 4071,78, as may be eaſily tried.

EXTRACTION of the ſquare roots of ſimple algebraic quantities.

The ſquare of aa is $+$ or $-a$; the ſquare-root of $9aa$ is $+$ or $-3a$; and that of $4aabb$ is $+$ or $-2ab$. This is plain; for the ſquare-root of any quantity, ſuppoſe of $4aabb$, is that which, being multiplied into itſelf, will produce $4aabb$. Now $-2ab$, multiplied into itſelf, will produce $4aabb$, as well as $+2ab$; and, therefore, one quantity is as much its ſquare-root as the other. When the ſquare-root of a quantity cannot be extracted, it is uſual to ſignify it by this mark $\surd$; thus $\surd 2aa$ ſignifies the ſquare-root of $2aa$; thus $\surd aa-4b$ is the ſquare-root of the whole quantity $aa-4b$; thus $\frac{\surd aa-4b}{2a}$ ſignifies a fraction, whoſe numerator is the ſquare-root of the whole quantity $aa-4b$, and whoſe denominator is $2a$; thus $\surd \frac{4ab-a^3}{12a}$ ſignifies the ſquare-root of the whole fraction $\frac{4ab-a^3}{12a}$; that is, the ſquare-root of both the numerator and denominator.

When the ſquare-root of a quantity cannot be extracted, the quantity may ſometimes, however, be reſolved into two factors, whereof the one is a ſquare, and the other is not: and whenever this is poſſible, the root of the ſquare may be extracted, and the radical ſign may be prefixed to the other factor: thus, $12aa = 4aa \times 3$; therefore $\surd 12aa = 2a \times \surd 3$.

EXTRACTION of the ſquare-roots of compound algebraic quantities.

The extraction of the ſquare-root of compound algebraic quantities is ſo very like that of whole numbers in common arithmetic, eſpecially in the caſe of ſeries, where it is chiefly required, that a bare inſpection of the work might be ſufficient: however, take the following directions, with an example.

Let it be required to extract the ſquare-root of $x^6+4x^5+10x^4+20x^3+25x^2+24x+16$. Here pointing every other place from the place of units, that is, from 16, I demand the ſquare-root of the member belonging to the firſt point to the left hand, that is, of x^6, and the anſwer is x^3, which I put down in the quotient; then I ſquare x^3, and ſubtract the product x^6 from x^6, and there remains nothing: then I bring down the two next members belonging to the next point; to wit, $4x^5+10x^4$, for a reſolvend, and divide it by $2x^3$, the double of the root in the quotient; that is, I divide $4x^5$ by $2x^3$, and the quotient is $2x^2$, which I put down in the quotient; as likewiſe after the diviſor $2x^3$; then I multiply the quantity $2x^3+2x^2$ by its laſt member $2x^2$, and the product $4x^5$
$+4x^4$

$+4x^4$ I ſubtract from the reſolvend $4x^5+10x^4$, and there remains $6x^4$; to this remainder I bring down the next two places, $20x^3+25x^2$, and ſo have a new reſolvend, which I divide by the double of the root already found, and do as before, till the whole be divided, as you may ſee in the work.

$$x^6+4x^5+10x^4+20x^3+25x^2+24x+16\,(x^3+2x^2+3x+4$$

x^6

$2x^3+2x^2)\ *+4x^5+10x^4$

$2x^2)\ \ 4x^5+4x^4$

$2x^3+4x^2+3x)\ *+6x^4+20x^3+25x^2$

$+3x)\ \ 6x^4+12x^3+9x^2$

$2x^3+4x^2+6x+4)\ *+8x^3+16x^2+24x+16$

$+4)\ \ 8x^3+16x^2+24x+16$

* * * *

Otherwiſe thus:

$$x^6+4x^5+10x^4+20x^3+25x^2+24x+16\,(x^3+2x^2+3x+4$$

x^6

$2x^3+2x^2)\ *$

$+2x^2)\ +4x^5+4x^4$

$2x^3+4x^2+3x)\ *\ \ 6x^4$

$+3x)\ \ 6x^4+12x^3+9x^2$

$2x^3+4x^2+6x+4)\ *+8x^3+16x^2$

$+4)\ \ 8x^3+16x^2+24x+16$

* * * *

Since the laſt member $+16$ was a ſquare, I might have begun the extraction at that end, and the root would have come out the ſame as before, but inverted.—16 is no ſquare number, ſince there is no root, either affirmative or negative, which, when multiplied into itſelf, will produce -16.

Let it be propoſed to extract the ſquare-root, or, at leaſt, to reduce the root to the ſimpleſt expreſſion of $12x^3-72x^2+108x$. This quantity, becauſe neither of the extremes are ſquares, muſt be reduced to a more convenient form, thus: If $12x^3$ be divided by $12x$, the quotient xx will be a ſquare number: therefore, I divide the whole by $12x$, and the quotient is $xx-6x+9$. Whence I conclude, *e converſo*, that if $xx-6x+9$, be multiplied into $12x$, the product will be the quantity propoſed: therefore $\sqrt{12x^3-72x^2+108x}$ is equal to $\sqrt{xx-6x+9}$ into $\sqrt{12x}$: but $\sqrt{x^2-6x+9}$, being extracted as above, is $x-3$, or $3-x$; and becauſe $12x=4\times 3x$, we have $\sqrt{12x}=2\times\sqrt{3x}$; therefore $\sqrt{12x^3-72x^2+108x}=x-3$ or $3-x$ into $2\times\sqrt{3x}=2x-6$, or $6-2x$ into $\sqrt{3x}$.

If the ſquare-root of the factor $xx-6x+9$ could not otherwiſe have been extracted, it might, however, have been obtained by an approximation, as in the following example:

To extract the ſquare-root of a binomial by an infinite ſeries. Though the ſquare-root of a binomial, as $a+b$, $1-z$, &c. cannot be expreſſed by any finite number of terms, yet by an infinite ſeries it may.

The ſquare-root of the binomial $1+x$, ſuppoſing x to be leſs than 1, is found by the following operation to be $1+\frac{1}{2}x-\frac{1}{8}x^2+\frac{1}{16}x^3-\frac{5}{128}x^4+$, &c. a ſeries, whoſe regularity is not immediately perceived; but it will appear in the courſe of this work, that theſe ſeries are as regular as any others whatſoever, and as eaſily computed.

$$1+x\quad *\ *\ *\ *\ *\ *\ *\ *$$

$2+\frac{x}{2})\ \frac{1}{*+x}\quad (1+\frac{x}{2}-\frac{x^2}{8}+\frac{x^3}{16}-\frac{5x^4}{128}+$ &c.

$+\frac{x}{2}\qquad x+\frac{x^2}{4}$

$2+x-\frac{x^2}{8})\ *-\frac{x^2}{4}$

$-\frac{x^2}{8}\qquad -\frac{x^2}{4}-\frac{x^3}{8}+\frac{x^4}{64}$

$2+x-\frac{x^2}{4}+\frac{x^3}{16})\ *+\frac{x^3}{8}-\frac{x^4}{64}$

$\frac{x^3}{16}\qquad \frac{x^3}{8}+\frac{x^4}{16}$

$2+x-\frac{x^2}{4}+\frac{x^3}{8}-\frac{5x^4}{128})\ *-\frac{5x^4}{64}$

$-\frac{5x^4}{128}\qquad -\frac{5x^4}{64}$

*

Since in theſe ſeries the powers of x aſcend or deſcend regularly, theſe roots may be extracted by the help of the coefficients only, and the powers may be ſupplied afterwards; but then due care muſt be taken to keep the terms diſtinct, ſo as to place all of the ſame kind orderly one under another, that no confuſion may ariſe in the operation. See BINOMIAL *Theorem*.

EXTRACTION of the cube root of algebraical quantities.—The method of extracting the cube root of algebraical quantities differs ſo little from that already delivered for extracting it numerically, that we preſume it will be needleſs to give any examples; we ſhall therefore only add the following theorem to ſhew the reaſon of theſe operations.

Suppoſe it were required to find the value of $x^3=G$. Put $r+y=G$, ſuppoſing r leſs than the true root; involve $r+y$ to the third power, and we ſhall have $r^3+3rry+3rry+y^3=x^3=G$; and $3rry+3ryy+y^3=G-r^3$; and $ry+y^2+\frac{y^3}{3r}=D$. Let $\frac{y^3}{3r}$ be rejected as of ſmall value; then it will be $ry+y^2=D$, which gives this theorem $\frac{D}{r+y}=y$. By this theorem, the examples given in extracting the cube-root numerically are performed.

EXTRAVASATION, in medicine, is applied to the blood, or any ſort of fluid, when got out of the veſſels in which it ought to be contained.

The word is Latin, *extravaſatio*, and derived from *extra*, out of, and *vas*, a veſſel.

EXTREME *and Mean Proportion*, in geometry, is when a line AB (plate LXIV. *fig.* 5.) is ſo divided in C, that the rectangle under the whole line AB, and the leſſer ſegment CB, is equal to the ſquare of the greater ſegment AC. The inveſtigation of which is as follows; let the given line $AB=a$, and for the greater ſegment put x, the leſſer will be $a-x$; then by the hypotheſis $a\times a-x=xx$, conſequently $aa=ax+xx$; and by compleating the ſquare, &c. we ſhall have $x=\sqrt{\frac{1}{4}aa}-\frac{1}{2}a$. Euclid, in lib. 2. prop. 11, gives the ſynthetical demonſtration of this: but this cannot be done exactly in any numbers; but if you would have it tolerably near, add together the ſquare of any number, and the ſquare of its half, and extract as near as you can the ſquare-root of the ſum; from whence, taking all the whole number, the remainder is the greateſt part.

EXTREMES, in logic, are thoſe terms in the concluſion of any ſyllogiſm that have a relation to ſome other term as a mean.

EXTRINSIC, among metaphyſicians, is taken in various ſenſes; ſometimes it ſignifies a thing not belonging to the eſſence of another; in which ſenſe the efficient cauſe and end of a thing are ſaid to be extrinſic. Sometimes it ſignifies a thing's not being contained within the capacity of another, in which ſenſe thoſe cauſes are called extrinſic, which introduce ſomething into a ſubject from without, as where a fire introduces heat. Sometimes it implies a thing added or applied to another, in which ſenſe accidents and adherents are ſaid to be extrinſic to the ſubjects to which they adhere. Sometimes the viſion is ſaid to be extrinſic from ſome form which does not exiſt in that thing, but is adjacent to it, or by ſome means or other without it. See the article INTRINSIC.

EXULCERATION, the ſame as ulcer; but it is generally applied to thoſe eroſions that begin to form an ulcer.

The word is Latin, *exulceratio*, and derived from *ex*, and *ulcer*, a bile.

EXUVIÆ, among naturaliſts, denote the caſt-off parts or coverings of animals, as the ſkins of ſerpents, caterpillars, and other inſects.

EXUVIÆ is alſo uſed for the remains of ſea-animals found foſſile, and more properly called extraneous, or marine foſſils.

EYE, in anatomy, the organ of ſight, or the inſtrument which repreſents viſible objects to the mind.

The whole body of the eye is a kind of teleſcope of infinite perfection, which tranſmits images in an exact and complete manner even to the bottom of it. This bottom is inveſted with textures of nerves, on which

the image is imprinted, and by that means the ſenſation is produced, of which one of theſe textures is the immediate organ.

In order to give a clearer idea of the ſtructure of the eye, and the mechaniſm of viſion, let us have recourſe to the camera obſcura, or dark chamber, which the eye in ſome meaſure reſembles.

Shut up a room ſo cloſe as to deprive it entirely of light. Then make a hole in one of the window ſhutters, and oppoſite this hole, at the diſtance of ſeveral feet, place a cloth or ſome white paſte board, on which all the objects without will be painted in the moſt lively and natural colours, though abſolutely reverſed. If theſe images are deſired to be repreſented in a more exact and more beautiful manner, let a lens be applied to the hole of the window-ſhutter, which, by collecting the rays, will form an image more compact and diſtinct. See CAMERA OBSCURA.

All that is wanting to render the camera obſcura, with regard to ſimple objects, an artificial eye, is the figure of a globe, and having the lens placed within the globe.

In the natural eye the globe or caſe is formed by ſupple membranes, and the lens by tranſparent bodies, and humours equally tranſparent.

The brain and nerves are compoſed, firſt, of a ſoft ſubſtance ſomewhat reſembling new cheeſe; and ſecondly of two integuments of a competent ſolidity, called the dura and pia mater, each of which is manifeſtly double; theſe three ſubſtances form all the nerves.

The principal nerves of the eye, called the optic nerves, A B (plate LXIV. *fig.* 6.) make their exit from the cranium, one on each ſide. They derive their origin from thoſe parts of the medullary center of the brain, called the beds of the optic nerves.

Then the two nerves K, K, tend towards the fore-part of the head, approaching again one towards the other, and unite as it were in a ſingle nerve A, without any croſſing or confuſion: they afterwards ſeparate one from the other, being ſtill incloſed in the pia mater, and inveſted with the anterior lobes of the brain; and after about ſeven lines diſtant from their ſeparation, they each of them enter into a bony cavity that leads to the orbit, the receptacle furniſhed by the brain for the eye: there they receive from the dura mater the ſheath common to all the nerves. This ſheath confines the nerve, and hinders it from becoming too bulky. This bony entrance forms a canal of about two lines; after which the dura mater is divided into two laminæ; one ſufficiently thin, *b* E, which lines the orbit, the other thicker, as D D, which continues to ſerve as a ſheath to the nerve. From the angle *b*, formed by the diviſion of theſe two laminæ, ariſe the muſcles of the eye.

The coat of the dura mater D D, that accompanies the optic nerve, and concurs to its formation, is continued in the center of the orbit amidſt the muſcles, about the ſpace of fifteen lines, after which it expands and dilates itſelf into a globe, much in the ſame manner as glaſs is blown in a bottle.

At the root of this expanſion, between the nerve and globe, the dura mater forms a circular band, by means of which it ſtrongly compreſſes the extremity of the nerve, and makes a ſort of valve, which ſeems to ſeparate the globe from the nerve, pretty much reſembling the paper ring applied to teleſcopes. It is formed like the valves of the inteſtines by a running fold of this coat: and it is evident that this fold was inevitable at the angle which the dura mater muſt make for the above-mentioned expanſion.

The dura mater D D (plate LXIV. *fig.* 7.), on thus expanding itſelf, forms the firſt, or exterior membrane, D *bc* of the globe of the eye, called the cornea. The anterior portion *bcb* of this cornea is tranſparent, and correſponds with the pupil; all the reſt is opaque.

Though the tranſparent cornea be a continuation of the ſclerotis, or opaque cornea D D D, it conſtitutes a part of the ſmaller ſphere, which ſeems added there in the manner chryſtals are to watches. By this means it projects a little beyond the common ſphere of the eye, which circumſtance renders it very well adapted to collect a greater quantity of rays and images, in regard of objects that preſent themſelves ſidewiſe to the eye.

The pia mater E, which is ſituated under the dura mater D, expands itſelf in a globe like the dura mater, in order to form the internal membranes, or to double the cornea. It alſo forms before its expanſion, a valve or circular band, which ſtrongly compreſſes the extremity of the nerve; but it is divided into two laminæ, one genuine and ſolid, that is applied exactly to the inner ſurface of the cornea D, where it is actually complicated and united to the other. M. le Cat firſt diſcovered this membrane, and demonſtrated its continuation with the pia mater, and its diſtinct extenſion, even almoſt to the tranſparent cornea.

The ſecond lamina of the pia mater, marked by long points in the figure, conſtitutes the choroides or uvea; but this lamina, properly ſpeaking, is only a texture of nerves and blood-veſſels that go out from the inner ſurface of the true lamina. Theſe veſſels convey a liquid that communicates a black or brown colour to this ſecond lamina. Part of theſe veſſels and nerves open on the internal ſurface of this lamina, and there form by that means a downy or mammillary texture loaded with the black liquor theſe veſſels are charged with. Ruyſch has made a particular coat of the choroides. This, according to us, would be the third coat diſtributed by the pia mater to the eye; namely, one truly membranous, united to the ſclerotis, one vaſcular, called the choroides, and one horny, ſtiled tunica Ruyſchii. Towards the fore part of the eye the choroides is doubled; and this exterior complication forms what is called the iris H H, in the middle of which is the perforation of the pupil. This iris is furniſhed with muſcular fibres in the form of rays and circles, by means of which the pupil dilates and contracts itſelf. It dilates itſelf in the ſhade, and in a paralytic ſtate of the optic nerves, by the repoſe or ſinking of its fibres, and is contracted when affected by light, particularly a ſtrong one, through the ſwelling of its fibres, into which this ſtrong light determines the ſpirits.

The inner complication of the choroides forms on the hinder part the corona ciliaris H H, in the center of which is encloſed the lens of the eye, called the chryſtalline humour. The corona ciliaris or ciliary proceſſes, on a cloſe examination, are the laſt nervous and vaſcular tufts or fringes, which expand themſelves on the inner ſurface of the choroides, where they form the ſecond coat and the corpus mammillare, which is the principal organ of ſenſation. They are plaited at this end like the wriſtband of the ſhirt; inaſmuch as from a large circumference, to which they were extended before, they are reduced to a very ſmall circle, that ſurrounds the chryſtalline humour. Theſe fringes, as they are floating, ſurpaſs a little the bounds of the exterior lamina of which the iris is a continuation.

The external lamina is complicated under the ciliary fibres, where it grows thickiſh and white. In this termination it ſeems to affect approaching to an ungulous nature, as much as can be expected from its delicacy; which indeed is the caſe of almoſt all textures formed by the parallel, cloſe, and compact, beds of nervous fringes.

The whole ſpace of the eye that is before the corona ciliaris I, I, and the chryſtalline humour K, is filled with a limpid water called the aqueous humour, in the center of which ſwims the iris or pupil H H. So that the iris divides this ſpace into two ſmall chambers; one before that is terminated by the tranſparent cornea, or exterior glaſs of the eye *bcb*; and the other on the back part a very ſmall one bounded by the corona ciliaris I, I, the chryſtalline humour K, or the lens of the eye, and the iris H H.

Next to theſe two chambers, behind the corona ciliaris and the cryſtalline humour, the globe of the eye forms a ſpace a great deal larger, K L, than the preceding ones. This ſpace is all occupied by a ſort of tranſparent jelly, called the vitreous humour. The cryſtalline humour K is lodged in the anterior ſurface of this jelly, like a diamond ſet in a ring.

The medullary and interior ſubſtance A of the optic

nerve is expanded as well as the preceding coats, and forms a fleſhy texture, marked by ſmall points in the plate.

This texture conſtitutes the inmoſt membrane of the globe of the eye, called the retina, and terminates at the corona ciliaris. This ſoft ſubſtance of the nerve, at the beginning of its expanſion, forms the ſmall medullary button B.

The extremely fine textures that divide the cavity of the eye, and form cells for the humours it is filled with, are the ſame which, in the cavity of the nerve, divide and ſupport the medullary ſubſtance therein exiſting.

Such is the ſtructure of the eye diſcovered by anatomy. But the lights derived from reaſon and analogous aſſiſtances, let us a great way farther into the nature of this wonderful organ. It is evident, that every individual ſenſation is produced by nervous papillæ; and that the fluid which animates theſe papillæ, receives by the glands the preparations and mixtures that fit it for receiving the ſenſation peculiar to each organ. It is well known, that theſe glands and nervous papillæ are often one and the ſame organ, and that they ſometimes even add to the preceding functions the filtration of a ſenſible liquid. The ſtructure is particularly remarkable in the glandulous papillæ of the tongue, that are at once the organs of the ſenſation of taſte, and the receptacles where the ſenſitive fluid receives its character, its mixture, and the reſervoirs of a filtrated liquid neceſſary to this ſenſation. The eye, all wonderful as it is, is nothing elſe but a glandulous papilla, of a larger ſize and expanſion, and hollower than the other glands. It is like them a triple organ of ſenſation, of preparation, of the ſenſitive fluid, and of filtration. The cloſeſt examination poſſible of this nervous papilla does not make it in the leaſt degenerate; on the contrary, it reflects a conſiderable luſtre on the ſtructure and uſe of thoſe papillæ, the univerſal organs of ſenſation. This ſtructure and theſe uſes, that have been hitherto a kind of myſtery, ceaſe almoſt to be ſo in the organ of ſight.

A glandulous papilla is a tuft and end of a nerve, deſtined to the filtration of ſome liquid. The eye is very evidently the extremity of the optic nerve, expanded, and blown, as it were, into a hollow ſphere full of fluids. One may trace the veſſels conveying thoſe fluids which form the expanded coats of the dura and pia mater, where they are interwoven, and open themſelves on the inſide of this organ. The ſize alone of theſe veſſels viſibly demonſtrates the filtration made there of the contained liquid, and the coats and cavity of this organ are nothing elſe than the prop and reſervoir of it.

The inſide of the glands is the concourſe of arterial and nervous extremities, in which concourſe the animal fluid is united to a volatile part of the arterial blood, to enable it to diſcharge its functions. This union is made by means of the nervous and vaſculating tufts: theſe tufts in the eye produce the down of the choroides. It is therefore highly probable, that the black liquid with which this down is imbued, is nothing elſe than the ſulphureous particles of the blood diffuſed in this texture by the tufts of the arteries, and loaded with the volatile portion that is mixed with the animal fluid, conveyed by the nervous tufts. Or, if you pleaſe, this black liquid is the dregs, as it were, of the fluid that reſults from the mixture of the ſpirits with the volatile part of the blood. The animal fluid partakes in ſome degree of the nature of mercury. Now mercury, intimately united with ſulphur, forms a black ſubſtance, an æthiops, as is well known. In like manner, there is the greateſt reaſon to imagine, that the eye preſents to us ſenſible traces of this ſo uſeful mixture; which we eſtabliſh on no other baſis than that of the neceſſity there ſeems to be for it, in regard of almoſt all the functions, and principally of muſcular motion.

However, this black liquid obſervable in the choroides is not peculiar to the eye; we meet with it on the inſide of almoſt all the glands: it is viſible in the glands of the kidnies; for which reaſon they are called capſulæ atrabiliariæ. It is likewiſe viſible in the pulmonary or bronchial glands. In ſhort, the colour of negroes has no other origin than this fable liquor, with which theſe cutaneous nervous tufts, being very porous, imbue the cuticle that inveſts them.

The down of the choroides, impregnated with the liquid we have been ſpeaking of, forms the inner membrane of the choroides. The exterior lamina this is ſuſtained by, is, in the organ of ſight, what the corpus reticulare is in the organ of the touch, and in that of the taſte. In all theſe organs, the veſſels and nerves, before their expanſion into tufts, are ſtripped of their thick coat; and it is of theſe ſpoils the texture is formed, which in the eye conſtitutes the exterior tunic of the choroides. The nervous papillæ being ſtripped in like manner become more delicate, and endued with a greater ſenſibility; and the texture made of their ſpoils ſerves to ſuſtain the nervous tufts and orifices of the veſſels that convey the neceſſary liquids, as well to the papillæ themſelves, as to the tranſparent humours contained in the globe.

As for the choroides, the veſſels are large enough to admit the ſulphureous particles of the blood to paſs along with the ſpirituous lymph; but beyond this membrane, the minuteneſs of the veſſels ſuffers only an extremely ſubtile lymph to flow, which forms and ſupplies the humours of the eye.

Of theſe the vitreous humour is the moſt conſiderable; it fills about three fourths of the globe of the eye towards the bottom of that organ, and is condenſed into a jelly; becauſe being embraced by all the coats of the optic nerve, and immediately by the medullary part of it, the retina, it is impregnated with a large quantity of this enlivening fluid, the property of which is to give a firmneſs and conſiſtence to the ſolids and fluids, where it is found in abundance.

The cryſtalline humour, for the ſame reaſon, ought to have this conſiſtence in a ſtill greater degree. For, beſides the preceding advantages which it has in common with the vitreous humour, its very ſmall circumference receives likewiſe by means of the corona ciliaris the concourſe of all the nervous extremities of the choroides. It muſt therefore be impregnated with a greater quantity of this fluid, and conſequently acquire a larger proportion of conſiſtence.

For the contrary reaſon, the liquid ſituated under the tranſparent cornea, and remote from this great influx of the conſervatory fluid, muſt fall ſhort in point of conſiſtence, and form a fluid of an aqueous nature.

What is very ſurpriſing, is the diſpoſal of theſe cauſes to produce effects ſo ſingularly peculiar to the organ they compoſe. A glandulous papilla of the tongue is only the extremity of a nervous fibre. This fibre could only form a nervous button full of a limpid liquid, which indeed was all that was neceſſary for it to do. But this would not have been ſufficient for the organs of ſight; more materials were requiſite: beſides, it is not here a nervous fibre, but an entire and very conſiderable nerve, which expands itſelf at once into a ſingle papilla, and by its thick coats forms a perfect and entire globe, which one would almoſt imagine to be impenetrable even to light itſelf; but this, however, is not true; for the exterior coat, which is the only one thick and ſubſtantial enough to complete the circumference of this globe, is naturally diſpoſed to terminate in a tranſparent lamina; and this lamina occurs preciſely at the entrance of the rays; for it can only occur at the extremity of this nervous body, as the nails can be formed only at the ends of the fingers.

The cornea therefore does not at all contradict its origin, but follows the common law of the nerves. The farther they recede from their origin, the harder and more compact they grow. The nails are formed by the extremities of the nerves of the legs and arms; theſe nails are hard and tranſparent, and would have an equal tranſparence with the cornea, if, like that, they were inceſſantly moiſtened with fluids. The cornea has no more tranſparence than the nails, when it is once abridged of its uſual ſupply of moiſture. Theſe parts therefore have the ſame nature, and the ſame origin.

The rays of light tranſmitted to the eye, ſtand in need of being there refracted, and collected in a particular manner; and an uniform fluid, like what is contained in all the glandulous papillæ, would not have effected

that buſineſs agreeable to this organ. But the inner ſubſtance of the larger nerve has provided for this contingency. It is the ſtream of a fluid that gives conſiſtence and ſolidity to all our parts; and its diſtribution is ſuch, that it imparts this conſiſtence preciſely in that order which the perfection of the organ demands. What a ſimplicity of mechaniſm is here to produce ſuch a prodigy of execution! A nerve expanded into a globe; its coats diſtinctly ſpread over one another; fluids collected under theſe coats by a very ordinary filtration; forms the whole apparatus.

EYE, in architecture, is applied to any round window made in a pediment, an Attic, the reins of a vault, or the like.

EYE *of a Block*, in naval affairs, that part of the rope-ſtrop which is faſtened to ſome neceſſary place in the ſhip: the ſtrop is a ſort of wreath, or rope, formed into a ring, and fixed round the block for the double convenience of ſtrengthening the block, and faſtening it in any place where it is wanted.

EYE *of a Dome* is an aperture at the top of the dome, as that of the Pantheon at Rome, or of St. Paul's at London; it is commonly covered with a lantern.

EYE *of the Volute*, in architecture, is the center of the volute, or that point in which the helix or ſpiral of which it is formed commences: or it is the little circle in the middle of the volute, in which are found the thirteen centers for deſcribing the ſeveral circumvolutions.

EYE, in agriculture and gardening, ſignifies a little bud, or ſhoot, inſerted into a tree by way of graft.

EYE *of a Tree*, a ſmall pointed knot to which the leaves ſtick, and from which the ſhoots or ſprigs proceed.

EYE-BROW, in anatomy. See SUPERCILIUM.

EYE-BROW, in architecture, is uſed in the ſame ſenſe as liſt or fillet. See FILLET.

Bull's EYE, in aſtronomy, a ſtar of the firſt magnitude in the conſtellation Taurus. See the article ALDEBARAN.

EYRE, in law, implies the itinerant courts of juſtice.

The word is formed from the old French, *erre*, *iter*, way, path, or track.

EZEKIEL, the name of a canonical book of the Old Teſtament, referring chiefly to the degenerate manners and corruptions of the Jews of thoſe times.

It abounds with elegant ſentences, and fine compariſons, and abundantly ſhews that the writer was no ſtranger to profane learning.

Ezekiel was carried captive to Babylon with Jechoniah, and began his prophecy in the fifth year of the captivity. He was cotemporary with Jeremiah, who propheſied at the ſame time in Judea. Ezekiel foretold many events, particularly the deſtruction of the temple, the fatal cataſtrophe of thoſe who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

EZEKIEL's *Reed*, or *Rod*, a meaſure of length mentioned by that prophet, and ſuppoſed to be nearly equal to two Engliſh feet.

EZRA, a canonical book of the Old Teſtament, comprehending the hiſtory of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. The author of this book was alſo the publiſher of the canon of the Old Teſtament.

F.

F, The fourth conſonant, and ſixth letter of the alphabet. The letter F is borrowed from the digamma or double gamma of the Ælians, as is evident from the inſcription on the pedeſtal of the coloſſus at Delos; and was undoubtedly formed from the old Hebrew Vau: and though this letter is not found in the modern Greek alphabet, yet it was in the ancient one, from whence the Latins received it, and tranſmitted it to us.

It is formed by a ſtrong expreſſion of the breath, and joining at the ſame time the upper-teeth and under-lip. It has but one ſort of ſound, which has a great affinity with *v* and *φ*, the latter being written for it by us in all Greek words, as *philoſophy*, &c. though the Italians write it *filoſofia*.

The Romans for ſome time uſed an inverted F, Ⅎ, inſtead of V conſonant, which had no peculiar figure in their alphabet. Thus, in inſcriptions we meet with TERMINAⅎIT, DIⅎI, &c. Lipſius and others ſay, that it was the emperor Claudius who introduced the uſe of the inverted digamma, or Ⅎ; but it did not long ſubſiſt after his death; for Quintilian obſerves, that it was not uſed in his time.

F or FA, in muſic, is the fourth note in riſing in this order of the gamut, *ut*, *re*, *mi*, *fa*. It likewiſe denotes one of the Greek keys in muſic, deſtined for the baſs.

F, in phyſical preſcriptions, ſtands for *fiat*, or let it be done. Thus F. S. A. ſignifies *fiat ſecundum artem*.

F was alſo a numeral letter, ſignifying 10, according to the verſe,

Sexta quaterdenos gerit quæ diſtat ab alpha.

And when a daſh was added at top, thus $\overline{F}$, it ſignified forty thouſand.

FABA, the bean, in botany, is comprehended by Linnæus among the viciæ. See the articles VICIA and BEAN.

FABER, in ichthyology, a fiſh of the zeus kind, called in Engliſh doree, or john dory. See the article ZEUS.

FABIANS, FABII, in antiquity, were prieſts of Pan, who were divided into two bodies, under the names of Quintilians and Fabians, to perpetuate the memory of Quintilius and Fabius, the former of which was head of Romulus's party, and the latter of Remus's.

FABLE, a tale, or feigned narration, deſigned either to inſtruct or divert, diſguiſed under the allegory of an action, &c. Jotham's beautiful fable of the trees is the oldeſt that is extant. Nathan's fable of the poor man and his lamb is the next in antiquity, and had ſo good an effect as to convey inſtructions to the ear of a king. We find Æſop in the moſt diſtant ages of Greece; and, in the early days of the Roman commonwealth, we find a mutiny appeaſed by a fable of the belly and the members. As fables had their riſe in the very infancy of learning, they never flouriſhed more than when learning was at its greateſt height: witneſs Horace, Boileau, and Fontaine.

Fable is the fineſt way of giving counſel, and moſt univerſally pleaſing, becauſe leaſt ſhocking; for in the reading of a fable, a man thinks he is directing himſelf, whilſt he is following the dictates of another, and conſequently is not ſenſible of that which is the moſt unpleaſing circumſtance in advice. Beſides, the mind is never ſo much pleaſed as when ſhe exerts herſelf in any action that gives her an idea of her own abilities; this natural pride of the ſoul is very much gratified in the reading of fable.

Poets have intermixed the fable with truth, to adorn their narration. Polybius, Strabo, and many other hiſtorians affirm, that the fable of the Iliad and Odyſſey of Homer is founded on truth, as appears from the ancient hiſtorians. The moſt remarkable writers who have handled moral fables, and introduced beaſts and trees ſpeaking, which ſort of fables is, ſtrictly ſpeaking, diſtinguiſhed by the name of apologue, was Æſop among the Greeks; not that he was the inventor, but becauſe he excelled therein, and Phædrus among the Latins. Some of the ancient critics after Aphthonius and Theon, reckon three kinds of fables; rational, called alſo parables; moral, called apologues; and mixed, compoſed of both ſorts. Beſides this kind there is another in which the actors are paſſions, virtues, vices, and ſuch like imaginary perſons, which in ſtrictneſs may be called allegory. Some of the ancient critics will have it that the Iliad and Odyſſey are fables of this nature. Spencer's Fairy Queen is one continued ſeries of them; and if we look into Cicero, Plato, Xenophon, and many others, we ſhall find that this was their favourite kind of fable; the greateſt Italian wits have alſo applied themſelves to this ſpecies of writing. The firſt fable of this ſort of any note, was that of Hercules meeting with Pleaſure and Virtue; invented by Prodicus, who lived before Socrates. He uſed to travel through Greece by virtue of this fable, telling it as ſoon as he had gathered an audience.

M. de la Motte calls the fable a little epic poem, differing only from it in the extent, and being leſs confined as to the choice of perſons; for it may comprehend all ſorts at pleaſure.

FABLE is alſo uſed for the plot of an epic or dramatic poem; and according to Ariſtotle, it is the principal part and ſoul as it were of a poem. In this ſenſe the fable is defined a diſcourſe invented with art to form the manners by inſtruction, diſguiſed under the allegory of an action. Ariſtotle divides the fable into ſimple and compound; the ſimple having no change of fortune; the compound, which hath a turn from bad fortune to good, and from good to bad. The contrivance of each fable muſt have two parts; namely, the intrigue and the diſcovery. Every fable muſt have theſe two parts to be the ſubject of a juſt poem. The compound fable pleaſes moſt, in Ariſtotle's opinion, as having variety: beſides, the fable muſt, to be perfect, be admirable and probable; the admirable is that part of it which is contrary to the ordinary courſe of nature; the probable is whatever ſuits with the common opinion. But the moſt part of thoſe that compoſe poems, by too great a paſſion to create admiration, take not ſufficient care to temper it with probability. Almoſt all the ancient poets, however

judicious

judicious in other reſpects, have been guilty of this fault; not to ſpeak of the moderns. Probability gives credit to whatever is moſt fabulous in poetry; it ſerves alſo to give a greater luſtre and air of perfection than even truth itſelf; for truth repreſents things only as they are, but probability renders them as they ought to be.

Dr. Trapp obſerves, though fable, action, and deſign, are often uſed indiſcriminately, they have each diſtinct ideas; defining fable, a compoſition of epiſodes and other things which are ſubſervient to the carrying on the action and bringing it to a concluſion.

FABRIC, the ſtructure or conſtruction of any thing, particularly a houſe, hall, church, &c.

The word is Latin, *fabrica*, and derived from *faber*, a workman. See the article BUILDING.

FABULOUS, ſomething conſiſting of, or connected with, a fable. See FABLE.

FABULOUS *Age*, among ancient hiſtorians. See the article AGE.

FACADE, n architecture. See FACE.

FACE, in anatomy. See the article HEAD.

FACE, in architecture, the front of a building, or the ſide which contains the chief entrance. It is alſo ſometimes uſed for the ſide which it preſents to the ſtreet, garden, court, &c. and ſometimes for any ſide oppoſite to the eye.

FACE *of a Stone*, in maſonry, that ſuperficies of it which lies in the front of the work. The workmen generally chuſe to make one of thoſe ſides the face, which, when in the quarry, lay perpendicularly to the horizon, and conſequently the breaking, not the cleaving way of the ſtone.

FACE, in fortification, an appellation given to ſeveral parts of a fortreſs, as the face of a baſtion, &c. See BASTION.

The face of a place is the front comprehended between the flanked angles of two neighbouring baſtions, being compoſed of a curtain, two flanks, and two faces; and is likewiſe called the tenaille of a place. In a ſiege, the attacks are carried on againſt both baſtions, when the whole tenaille is attacked.

Prolonged FACE, that part of the line of defence-razant, which is between the angle of the ſhoulder and the curtain, or the line of defence-razant, diminiſhed by the length of the face.

FACE *of a Gun*, the ſuperficies of the metal at the extremities of the muzzle of the piece.

FACE, in the military art, a word of command, intimating to turn about: thus, *face to the right*, is to turn upon the left heel a quarter-round to the right; and, *face to the left*, is to turn upon the right heel a quarter-round to the left.

FACE *of Plants*, among botaniſts, ſignifies their general appearance, which, being nearly the ſame in plants of the ſame genus, ſerves to diſtinguiſh them at firſt ſight.

FACET, or FACETTE, among jewellers, the name of the little faces or planes to be found in brilliant and roſe diamonds. See the article DIAMOND.

FACTION, a cabal or party formed in a ſtate, city, or company.

FACTION, in antiquity, a name given to the different companies of combatants in the circus.

FACTITIOUS is any thing made by art, and is uſually taken in oppoſition to natural. Thus ſope is a factitious body or concrete, but fuller's earth is a natural one.

The word is Latin, *factitius*, and derived from *facio*, to do, or perform.

FACTOR, in commerce, is an agent or correſpondent reſiding beyond the ſeas, or in ſome remote part, commiſſioned by merchants to buy or ſell goods on their account, or aſſiſt them in carrying on their trade.

FACTOR, in multiplication, a name given to the multiplier and multiplicand, becauſe they conſtitute the product. See the article MULTIPLICATION.

FACTORAGE, called alſo commiſſion, is the allowance given to factors by the merchant who employs them.

FACTORY is a place where a conſiderable number of factors reſide to negotiate for their maſters or employers.

FACTUM, in arithmetic, the product of two quantities multiplied by each other.

FACULÆ, in aſtronomy, are ſhining parts which the moderns have ſometimes obſerved upon the ſun's diſk; but they are very ſeldom ſeen.

The word is Latin, from the plural of *facula*, a little torch.

Kircher and Scheiner conceive them to be a ſort of volcanos in the body of the ſun. But Huygens and others attribute the cauſe of theſe phœnomena to the tremulous agitation of the vapours near our earth; the ſame as ſometimes ſhew a little unevenneſs in the circumference of the ſun's diſk, when viewed through a teleſcope.

FACULTY, in law, a privilege granted to a perſon, by favour and indulgence, of doing what, by law, he ought not to do.

For granting theſe privileges, there is a court under the archbiſhop of Canterbury, called the court of the faculties, the chief officer of which is ſtiled maſter of the faculties; who has a power of granting diſpenſations in divers caſes, as to marry without the banns being firſt publiſhed; to ordain a deacon under age; for a ſon to ſucceed his father in his benefice; a clerk to hold two or more livings, &c.

FACULTY, in the ſchools, a term applied to the different members of an univerſity, divided according to the arts and ſciences taught there.

FACULTY *of Advocates*, a term applied to the college or ſociety of advocates in Scotland, who plead in all actions before the court of ſeſſion.

FACULTY is alſo uſed to denote the powers of the human mind, viz. underſtanding, will, memory, and imagination. See the article UNDERSTANDING, &c.

FÆCES, properly the lees or grounds of any fermented liquor; but generally, in medicine, it is underſtood of wine; though the ſediment of any liquid is called fæx or fæces: by this is alſo underſtood the excrements of the belly.

FÆCES, in chemiſtry, whatever remains in the veſſel after diſtillation, &c.

FÆCULA, in pharmacy, a medicine which conſiſts of the fæces of vegetable juices, chiefly thoſe of roots.

The word is Latin, being a diminutive of *fæx*, ſediment, or lees.

FÆCULENT, in general, is applied to things abounding with fæces, or dregs: thus the blood and other humours of the human body, are ſaid to be fæculent, when without that purity which is neceſſary to health.

FAG-END, in the ſea-language, the end of any rope which is untwiſted and looſened by frequent uſe: to prevent this, the ends of ropes are generally well faſtened by binding a piece of ſmall cord or packthread around them, which is called whipping them.

FAGONA, in anatomy, a conglomerate gland, the ſame with thymus. See THYMUS.

FAGONIA, the cretic trefoil, in botany, a genus of plants, the corolla of which conſiſts of five cordated patent petals, with long ſlender ungues inſerted in the cup; the fruit is a roundiſh acuminated capſule, compoſed of ten valves, which form five lobes, and as many compreſſed cells; the ſeed is ſingle, and of a roundiſh figure.

FAGOPYRUM, buck-wheat, in botany. See BUCK-WHEAT.

FAGOTTINO, in muſic, is a ſingle curtail, a muſical inſtrument ſomething like the baſſoon. See BASSOON.

FAGOTTO, in muſic, the double curtail, or in reality a double baſſoon, as big again as the former.

FAGUS, the beech, in botany. See BEECH TREE.

FAILURE, a ſpecies of bankruptcy, commonly called breaking, or ſtopping payment. See BANKRUPTCY.

FAINT-ACTION, in law, a feigned action, or ſuch as, although the words of the writ are true, yet, for certain cauſes, the plaintiff has no title to recovery thereby.

FAINT PLEADER, in law, a covinous, falſe, or colluſory manner of pleading, to the deceit of a third perſon.

FAINTING. See LIPOTHYMIA.

FAIR, a greater kind of market, granted to a town, by privilege, for the more ſpeedy and commodious providing

viding of ſuch things as the place ſtands in need of. See the article MARKET.

FAIRY, or FARY, in ancient traditions and romances, denotes a kind of imaginary genii, converſant on earth, and diſtinguiſhed by abundance of fantaſtical actions and offices, good or evil. Fairies are of Oriental extraction, and ſeem to have been invented by the Perſians and Arabs, whoſe hiſtory and religion abound with tales of the fairies and dragons. The Perſians call them Peri, the Arabs Ginn, having a peculiar country which they ſuppoſe them to inhabit, called Ginniſtan, by us Fairy-land.

Spenſer's Fairy Queen is an epic poem, under the perſons and characters of the fairies. In this kind of writing, the poet loſes ſight of nature, and entertains his readers with characters of fairies, witches, magicians, demons, and departed ſpirits. It requires an odd turn of thought, and an imagination naturally fruitful and ſuperſtitious. The poet ought likewiſe to be well verſed in legends, fables, antiquated romances, and the tradition of our nurſes, in order to fall in with thoſe natural prejudices and notions which we have imbibed in our infancy.

The whole ſubſtance of this poetry owes its original to the darkneſs and ſuperſtition of later ages, when pious frauds were made uſe of to amuſe or frighten mankind into a ſenſe of their duty. Among the Engliſh poets Shakeſpeare has incomparably excelled all others, particularly in his Macbeth, his Midſummer Night's Dream, &c.

This ſort of poetry raiſes a pleaſing kind of horror in the mind, and amuſes the imagination with the ſtrangeneſs and novelty of the perſons repreſented therein. They bring up into our memory the ſtories we have heard in our childhood, and favour thoſe ſecret terrors and apprehenſions, to which we are naturally ſubject. Men of cool tempers object to this kind of poetry, that it has not probability enough to affect the imagination.

FAIRY-CIRCLE, or RING, is a phœnomenon pretty frequent in the fields, &c. being a kind of circle, which the vulgar ſuppoſe to be traced by the fairies in their dances.

There are two kinds of it; one of about three yards in diameter, containing a bare path about a foot broad, with graſs growing in the middle. Meſſ^rs. Jeſſop and Walker, in the Phil. Tranſ. aſcribe them to lightning, which is confirmed by their being moſt frequently after ſtorms of that kind, as well as by the colour and brittleneſs of the graſs's roots, when firſt obſerved. Lightning, like all other fires, moves round and burns more in the extremity than the middle; the ſecond circle ariſes from the firſt, the graſs burnt up growing more plentifully afterwards. Others maintain that theſe circles are made by ants, which are frequently found in great numbers therein.

FAITH, *Fides*, in antiquity, was deified by the Romans, and had a temple in the Capitol.

Public faith is repreſented on medals ſometimes with a baſket of fruit in one hand, and ſome ears of corn in the other; and ſometimes holding a turtle-dove. But the moſt uſual ſymbol is with her two hands joined together.

FAITH, in divinity and philoſophy, the firm belief of certain truths upon the teſtimony of the perſon who reveals them.

The grounds of a rational faith are, 1. That the things revealed be not contrary to, though they may be above natural reaſon. 2. That the revealer be well acquainted with the things he reveals. 3. That he be above all ſuſpicion of deceiving us.

Where theſe criterions are found, no reaſonable perſon will deny his aſſent: thus, we may as well doubt of our exiſtence, as of the truth of a revelation coming from God, who can neither be deceived himſelf, nor deceive others by propoſing things to be believed, that are contradictory to the faculties he has given us. Whatever propoſitions, therefore, are beyond reaſon, but not contrary to it, are, when revealed, the proper matter of faith.

Confeſſion of FAITH. See CONFESSION.

FAITHFUL, an appellation aſſumed by the Mahometans. See MUSSULMEN.

FAKE, among ſailors, when a cable or other rope is laid in a proper diſpoſition for ſtowage aboard ſhip, it is winded round and round in a ſerpentine revolution; this winding is called coiling, and each of the turns thereof is called a fake; ſix or eight fakes compoſe what is called a tier; and the whole cable conſiſts of a greater or leſs number of theſe tiers, which lie all above one another in the manner deſcribed, according to the room or extent of ſpace in which it is coiled.

FAKIR, in pagan theology, a kind of Indian monks, who even outdo the mortifications and ſeverities of the ancient Chriſtian anchorets.

Some of them mangle their bodies with ſcourges and knives; others never lie down; and others remain all their lives in one poſture.

There are alſo another kind of fakirs, who do not practiſe ſuch ſeverities; theſe flock together in companies, and go from village to village, propheſying and telling fortunes. It is ſaid that even perſons of fortune, in India, become fakirs, and that there are more than two millions of them.

FALCATED, ſomething in the form of a ſickle: thus, the moon is ſaid to be falcated when ſhe appears horned. See the articles MOON and PHASIS.

FALCO, in ornithology, a genus of birds, of the order of the accipitres, with three toes always before, and only one behind.

This genus comprehends the falcon kind, properly ſo called, the hawk, gyrfalcon, eagle, buzzard, pygargus, lannar, kite, keſtril, &c.

FALCON, or FAUCON, in gunnery, a piece of cannon. See the article CANNON.

FALCONET, or FAUCONET. See the article CANNON.

FALCONRY, the art of taming, managing, and tutoring hawks and falcons to catch their prey.

The word is French, *fauconerie*, which ſignifies the ſame.

The terms of falconry, and what we know of the art itſelf, we borrow from the French. The grand ſeignior uſually keeps ſix thouſand falconers in his ſervice; and the French king has a grand falconer. Hiſtorians take notice of this poſt as early as 1250. Falconry, as now practiſed, was unknown to the Greeks and Romans.

FALDAGE, an ancient privilege reſerved to lords, of ſetting up folds for ſheep in any fields within their manors, for the better manuring of the ſame; and this, in former times, was uſually done as well with their tenants ſheep, as with their own.

FALDFEY, or FALDFEE, a rent or fee paid by ſome cuſtomary tenants, for liberty to fold their ſheep on their own lands.

FALL, the deſcent of a heavy body towards the center of the earth. See the articles DESCENT, GRAVITY, ACCELERATION, &c.

FALL is alſo the name of a meaſure of length uſed in Scotland, and containing ſix ells of that country. See MEASURE and ELL.

FALLACY, a deception, fraud, or falſe appearance.

FALLACY, or *Syllogiſtical* FALLACY, in logic, a captious argument, which, on account of its apparent goodneſs and defect, is made uſe of to deceive a reſpondent not well verſed in the art of ſophiſtry. See the article SOPHISM.

FALLING-SICKNESS, the ſame with epilepſy. See EPILEPSY.

FALLOPIAN TUBES, in anatomy, are appendages of the uterus. See the article GENERATION.

FALLOW, a pale red colour, like that of brick half burnt: ſuch is that of a fallow deer. See the article DEER.

FALLOW-FIELD, or FALLOW-GROUND, land laid up, or that has lain untilled for a conſiderable time.

FALLOWING *of Land*, a particular method of improving land.

The great benefit of fallowing appears by the common practice of landlords, who every where take care to oblige their tenants to a ſtrict obſervance of it once in three years; few lands being able to bear two crops without it.

It appears that none will find a year's fallowing a loſs to them, let their land be what it will; but, more particularly,

cularly, the advantage of fallowing conſiſts in, firſt, its laying the land in ridges, and its expoſing it to the froſt, wind, ſun, and dews, all which ſweeten and mellow the land very much; the often ſtirring of it, and breaking the clots, diſpoſe it for the bearing of good crops. Secondly, it kills the weeds, by turning up the roots to the ſun and air; and kills not only the weeds that grew with the laſt corn, but wild oats, darnel, and other weeds that ſow themſelves, and that as ſoon as they begin to peep out of the ground; ſo that they have no time to ſuck out any of the heart of the land.

The way of ordering fallow-lands is, after the crop is off, to let the land lie all winter, and what graſs and weeds grow on it, to eat off with ſheep in April, or beginning of May. As ſoon as they have done ſowing of corn, they begin to plow up their fallows. This firſt fallowing in many places, ought to be very ſhallow, well turned, and clapped cloſe together, becauſe the thinner the turf is, the eaſier will it dry through, and kill the weeds, eſpecially if the weather be dry: but, in ſome places, where there is a very cold clay, that will not bear corn well without being expoſed to the heat of the ſun to warm it, they plow their firſt plowing the depth they deſign to go. About June is the time of the ſecond plowing, which they call twy-fallowing; at which plowing, you muſt go your full depth. About the latter end of July, or the beginning of Auguſt, is the time of try-fallowing, or laſt plowing, before they ſow their rye or wheat: but ſome plow up their land oftener.

If the land riſe full of clots, and if it is a binding land, you muſt make it fine by harrowing of it, when rain comes; but then you muſt not let it lie long before you ſtrike, ſiſe, or plow it up into ſmall ridges, eſpecially if it is wet land; and as near as you can, leave no weeds, turfs, or graſs unkilled, or unbroke with your harrows. But if your land will diſſolve well with the froſt, it is beſt to let it lie a little rougher, eſpecially if you deſign to ſow it with barley; for the rougher it lies for a winter-fallowing, the better. If the winter does not diſſolve the clots, which it will not do in binding lands, you muſt wait rain for the fallowing of it. Where the land is but indifferent, and the manure is not to be got, fallowing every other year is found a great improvement. In ſome places they take a crop of wheat, and a crop of peaſe, and ſo fallow their land again.

FALSE, in general, ſomething contrary to truth, or not what it ought to be: thus we ſay, a falſe witneſs, falſe action, falſe weights, falſe claim, &c. See the articles WITNESS, ACTION, &c.

FALSE *Impriſonment*. See IMPRISONMENT.

FALSE *Judgment*. See JUDGMENT.

FALSHOOD, in philoſophy, an act of the underſtanding repreſenting a thing otherwiſe than it is as to its accidents.

FALX, in anatomy, is a duplicature of the dura mater; ſo called from its curvature. See BRAIN.

The word is Latin, and literally ſignifies a ſickle.

FAMILIARS *of the Inquiſition*, are people that aſſiſt in the apprehending of ſuch perſons as are accuſed, and to carry them to priſon; upon which occaſion, the unhappy perſon is ſurrounded by ſuch a number of theſe officious gentlemen, that there is no poſſibility of eſcaping out of their hands. As a reward of this baſe employ, the familiars are allowed to commit the moſt enormous actions, to debauch, aſſaſſinate, and kill, with impunity. See the article INQUISITION.

FAMILY, *Familia*, denotes the perſons that live together in one houſe, under the direction of one head or chief manager. It alſo ſignifies the kindred or lineage of a perſon, and is uſed by old writers for a hide or portion of land ſufficient to maintain one family. See the article HIDE.

FAMILY, in natural hiſtory, a term uſed by authors to expreſs any order of animals, or other natural productions of the ſame claſs. See CLASS and ORDER.

FAMILY *of Curves*. See CURVE.

FAN, a machine uſed to raiſe wind and cool the air by agitating it.

FAN is alſo uſed as an inſtrument for winnowing corn.

FANATICS, wild, enthuſiaſtic, viſionary perſons, who pretend to revelation and inſpiration.

FANCY, or IMAGINATION. See IMAGINATION.

FANIONS, in the military art, ſmall flags carried along with the baggage.

FANUM, TEMPLE. See TEMPLE.

FAPESMO, a form of ſyllogiſm, wherein the major or firſt propoſition is an univerſal affirmative, the minor an univerſal negative, and the concluſion a particular negative.

FARCE originally implied thoſe little pieces of drollery exhibited by mountebanks and their buffoons, in the open ſtreets, to gather the people together.

The word is French, and ſignifies forced meat or ſtuffing.

Farce is at preſent of more dignity: it is removed from the ſtreet to the theatre, and inſtead of being performed by merry-andrews to amuſe the rabble, is acted by comedians, and become the entertainment of a polite audience. Poets have reformed the wildneſs of the primitive farces, and brought them to the taſte and manner of comedy. The difference of the two upon the Engliſh ſtage is, that comedy keeps to nature and probability, and therefore is confined to certain laws preſcribed by ancient critics; whereas farce diſallows of all laws, or rather ſets them aſide on occaſion. Its end is purely to make merry, and it ſticks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is uſually low, the perſons of inferior rank, the fable or action trivial or ridiculous, and nature and truth every where exaggerated to afford the more palpable ridicule. The ancient farces ſeem to have been a true imitation of the antique mimes. Our modern farces are now denominated entertainments.

FARCIMINALIS TUNICA, in anatomy, the ſame with the allantois. See ALLANTOIS.

FARCIN, or FARCY, in farriery, a diſtemper of the blood-veſſels, which generally follows the courſe of the veins, and when inveterate thickens their coats and integuments.

At firſt one or more ſmall ſwellings, or round buds like grapes or berries, ſpring out over the veins, and are often exquiſitely painful to the touch; in the beginning they are hard, but ſoon turn into ſoft bliſters, which, when broke, diſcharge an oily or bloody ichor, and turn into very foul and ill diſpoſed ulcers. In ſome horſes it appears on the head only; in ſome on the external jugular; in others on the plate vein, and runs downwards on the inſide of the fore-arm towards the knee, and very often upwards towards the briſket; in ſome the farcy ſhews itſelf on the hind parts, about the paſterns, and along the large veins on the inſide of the thigh, riſing upwards into the groin, and towards the ſheath; and ſometimes the farcy makes its appearance on the flanks, and ſpreads by degrees towards the lower belly, where it often becomes very troubleſome.

When the farcy appears on the head only, it is eaſily cured; eſpecially when it is ſeated in the cheeks and forehead, the blood veſſels being here ſmall; but it is more difficult when it affects the lips, the noſtrils, the eyes, and kernels under the jaws, and other ſoft and looſe parts, eſpecially if the neck vein becomes chorded. When it begins on the outſide of the ſhoulder or hips, the cure is ſeldom difficult; but when the farcy ariſes on the plate vein, and that vein ſwells much, and turns chorded, and the glands or kernels under the arm-pit are affected, it is hard to cure; but more ſo when the crural veins within ſide of the thigh are chorded, and beſet with buds, which affect the kernels of the groin, and the cavernous body of the yard. When the farcy begins on the paſterns or lower limbs, it often becomes very uncertain, unleſs a timely ſtop is put to it; for the ſwelling in thoſe dependant parts grows ſo exceſſively large in ſome conſtitutions, and the limbs ſo much diſfigured thereby with foul ſores and callous ulcerations, that ſuch a horſe is ſeldom fit for any thing afterwards, but the meaneſt drudgery: but it is always a promiſing ſign, wherever the farcy happens to be ſituated, if it ſpreads no farther. It is uſual to affect only one ſide at a time, but when it paſſes over to the other, it ſhews great malignancy; when it ariſes on the ſpines, it is then for the moſt part dangerous, and is always more ſo to horſes that are fat and full of blood, than to thoſe that are in more moderate caſe. When the farcy

is epidemical, as ſometimes happens, it riſes on ſeveral parts of the body at once, forms naſty foul ulcers, and makes a profuſe running of greeniſh bloody matter from both noſtrils; and ſoon ends in a miſerable rot.

From this deſcription of the farcy, it will appear how greatly thoſe may be diſappointed, who depend on ſome ſingle ſpecific drink or ball for a certain cure; for the ſymptoms are ſometimes ſo favourable, that it is eaſily conquered by a very ſimple management; and when it ariſes ſuperficially upon the ſmaller veſſels, it will often go off, with moderate labour, without any other means than bleeding. Such inſtances as theſe may eaſily give a reputation to things of no great efficacy, and bring them into eſteem: but whoever has acquired any true notion of the farcy, will know that this diſtemper is not to be conquered but by ſuch things as are fitly adapted to the various ſymptoms that occur in the different ſtages of it. To avoid therefore the perplexity that ariſes from the various complications ſo uſual in the farcy, we ſhall conſider it in its different ſtates, or degrees, viz. when it ſeizes only the ſmaller veſſels; when the larger veins are chorded, and the feet, paſterns, and flanks affected: and laſtly, when the farcy beginning on one ſide only, breaks out on the other alſo, and affects the whole body.

When the farcy makes its firſt appearance on the head, it riſes on the cheeks and temples, and looks like a network, or ſmall creeping twigs full of berries. Sometimes it inflames the eye, and ſometimes little bliſters or buds run along the ſide of the noſe. It ariſes often on the outſide of the ſhoulder, running along the ſmall veins with heat and inflammation; and ſometimes a few ſmall buds appear near the withers, and on the outſide of the hip. In all theſe appearances, the diſeaſe being ſuperficial, and affecting only the ſmaller veſſels, is eaſily conquered by the following method, when taken in time; for the ſimpleſt farcy, if neglected, may degenerate into the worſt ſort.

This diſtemper then being of an inflammatory nature, and in a particular manner affecting the blood veſſels, muſt neceſſarily require large bleeding, particularly where the horſe happens to be fat and full of blood. This always checks the beginning of a farcy, but is of ſmall ſervice afterwards; and if a horſe is low in fleſh, the loſs of too much blood ſometimes proves injurious. After bleeding, let the horſe have four ounces of cream of tartar and lenitive electuary; which may be given every other day for a week, to cool the blood, and open the body; and then give nitre three ounces a day, for three weeks or a month; and anoint the buds and ſwellings with the following ointment twice a day.

"Take ointment of elder four ounces, oil of turpentine two ounces, ſugar of lead half an ounce, white vitriol powdered two drams; mix together in a gally-pot."

The buds ſometimes by this method are diſperſed, leaving only little bald ſpots, which the hair ſoon covers again. When they break and run, if the matter be thick and well digeſted, they will ſoon be well: but in order to confirm the cure, and to diſperſe ſome little lumps, which often remain for ſome time on the ſkin without hair, give the liver of antimony for a month; two ounces a day for a fortnight, and then one a day for the other fortnight; by following this method, a farcy which affects only the ſmall veſſels, may be ſtopped in a week or ten days, and ſoon after totally eradicated.

When the farcin affects the larger blood veſſels, the cure is more difficult; but let it always be attempted early: therefore, on the plate, thigh, or neck veins appearing chorded, bleed immediately on the oppoſite ſide, and apply the following to the chorded vein.

"Take oil of turpentine in a pint bottle ſix ounces, oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by little at a time, otherwiſe the bottle will burſt; when it has done ſmoaking, drop in more oil of vitriol, and ſo on till all is mixed."

This mixture is one of the beſt univerſals in a beginning farcy; but where it is ſeated in looſe fleſhy parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are neceſſary.

Rub the parts firſt with a woollen cloth; and then apply ſome of the mixture over the buds, and wherever there is any ſwelling, twice a day. Give the cooling phyſick every other day, and then three ounces of nitre every day for ſome time. This method muſt be continued till the buds digeſt, and the chord diſſolves; and when the ſores run plentifully, the matter digeſts well, and the lips and edges are no ways thick or callous, you may expect a ſpeedy recovery; yet to confirm the cure, and prevent a relapſe, give the liver of antimony or crude antimony, as before directed; and to heal the ſores and ſmooth the ſkin, dreſs with bees-wax and oil. *Bartlet's Farriery.*

FARDING-DEAL, the fourth part of an acre of land. See the article ACRE.

FARE moſt commonly ſignifies the money paid for a voyage, or paſſage, by water; but, in London, it is what perſons pay for being conveyed from one part of the town to another in a coach or chair.

FARINA, a Latin term ſignifying meal, or the flour of corn.

FARINA FOECUNDANS, among botaniſts, the impregnating meal or duſt on the apices or antheræ of flowers; which being received into the piſtil, uterus, or ſeed veſſel of plants, fecundates the rudiments of the ſeeds in the ovary, which otherwiſe would decay and come to nothing. See the article GENERATION *of Plants.*

FARLEY, or FARLIEU, money paid by tenants in the weſt of England, in lieu of a heriot. See the article HERIOT.

FARM, or FERM, ſignifies the chief meſſuage in a village, or any large meſſuage whereto belongs land, meadow, paſture, wood, common, &c. and which has been uſed to let for term of life or years, under a certain yearly rent payable by the tenant for the ſame.

FARMER, the perſon who occupies or is leſſee of a farm, whether for life or years.

FARMER, among miners, ſignifies the lord of the field, or the perſon who farms the lot and cope of the king.

FARRIER, one whoſe employment is to ſhoe horſes, and cure them when diſeaſed or lame.

FARRIERY, the art of trimming the feet, and curing diſeaſed horſes. See HORSE.

FARTHING, the leaſt copper coin uſed in Britain; being half of the half-penny. See the article EXCHANGE.

FASCES, in Roman antiquity, axes bound up together with rods or ſtaves, and carried before the Roman magiſtrates as a badge of their authority and office.

FASCETS, in the art of making glaſs, are the irons thruſt into the mouths of bottles, in order to convey them into the annealing tower.

FASCIA, in architecture, ſignifies any flat member having a conſiderable breadth and but a ſmall projecture, as the band of an architrave, larmier, &c.

Faſcias, in brick buildings, are certain juttings out of the bricks over the windows of each ſtory, except the upper one. Theſe are ſometimes plain, like thoſe of columns; but ſometimes they are moulded, and the moulding is uſually a ſcima reverſa at the bottom, above which are two plain courſes of bricks, then an aſtragal, and laſtly, a boultin. See the articles ASTRAGAL and BOULTIN.

FASCIA LATA, in anatomy, the name of a muſcle, or muſcular ligament.

It is very conſiderable for its extent and ſtrength, being compoſed principally of two planes of fibres, of which the external are more or leſs longitudinal; the internal more or leſs tranſverſe. It is further ſtrengthened in ſome places by a great number of other fibres, which augment its thickneſs, and form particular expanſions. The tranſverſe fibres are much ſtronger than the longitudinal.

It is fixed above to the criſta of the os ilium, from the large tuberoſity, to the anterior ſuperior ſpine, to the ligamentum Fallopii, and to the aponeuroſis of the obliquus externus of the abdomen, on which it runs up by a thin lamina. It is likewiſe fixed in the lateral inferior part of the os ſacrum, and to the neighbouring parts of the ligaments, by which that bone is connected to the ilium and iſchium.

From thence it advances over the glutæi and thigh, between the membrana adipoſa and muſcles, down to the anterior and outer parts of the knee. It is very thin on the

the patella: it is alſo continued over the external anterior part of the tibia covering the muſcles thereof, and is ſtrongly inſerted in the head and criſta of that bone, and in the upper part of the fibula.

It ſends off elongations, which, like ſcepta, run in between the muſcles, and ſometimes meet ſo as to form vaginæ. It is ſtrongeſt on the anterior and outer parts of the thigh, growing gradually thinner on the inner and back parts.

It is ſtrongly inſerted in the linea femoris aſpera, between the vaſtus externus and biceps, forming a ſeptum between theſe. It furniſhes particular vaginæ to the muſcles, on the inſide of the thigh, which vaginæ, though thin, are pretty ſtrong, principally conſiſting of tranſverſe fibres.

The muſculus FASCIÆ *Latæ* is a ſmall and pretty long muſcle, ſituated ſomewhat obliquely upward and downward, on the fore-part of the hip. It is fixed above to the outſide of the anterior ſuperior ſpine of the ilium, between the inſertions of the glutæus medius and ſartorius. Thence its fleſhy fibres run down a little obliquely backward, forming a very flat body, four fingers breadth in length, and two in breadth.

This body lies between two laminæ of the faſcia, and is inſerted therein by ſhort tendinous fibres, which diſappear, at that place where the faſcia adheres to the great trochanter and tendon of the glutæus maximus. *Winſlow's Anat.*

FASCIÆ, in aſtronomy, ſeveral rows of bright ſpots on Jupiter's body, reſembling belts or ſwaths.

Theſe faſciæ or belts are more lucid than the reſt of the planet's diſk, and are terminated by parallel lines. Some have imagined that they are long canals of ſome fluid matter, or water; and, becauſe they have diſcovered ſeveral dark ſpots on his diſk, they conclude that the planet's ſurface is divided into land and water, like that of our globe.

FASCIALIS, in anatomy, is the ſame with faſcia lata. See FASCIA LATA.

FASCICULUS, in medicine, denotes a handful; or, according to others, as much as can be taken up between two fingers and the thumb.

The word is Latin, being a diminutive of *faſcis*, a bundle.

FASCINATION, a kind of witchcraft or enchantment, ſuppoſed to operate by the influence either of the eye or tongue.

FASCINES, or FAGGOTS, in fortification, are ſmall branches of trees or bavens bound up in bundles, which are uſed in an army, in order to cover themſelves, and burn the enemies lodgments; and which, when mixed with earth, ſerve to fill up ditches, mend roads, &c.

FASHION, a term uſed among artificers in gold and ſilver, for the trouble, time, and labour employed in a piece of work. It is by the faſhion that workmens wages are regulated.

FASHION-PIECES, in ſhip-building, the aftmoſt or hindmoſt of the timbers of a ſhip, which limit the breadth and form the ſhape of the ſtern. See the article SHIP-BUILDING.

FAST, or FASTING, in general, denotes the abſtinence from food; but is more particularly uſed for ſuch abſtinence on a religious account.

FAST-DAYS, thoſe appointed, by public authority, to be obſerved in faſting and humiliation.

FAST-GROUND, or FAST-COUNTRY, among miners, denotes the ſame with ſhelf. See the article SHELF.

FASTERMANS, among our Saxon anceſtors, were pledges or bondſmen, who were anſwerable for each other's good behaviour.

FASTI, in Roman antiquity, the calendar wherein were expreſſed the ſeveral days of the year, with their feaſts, games, and other ceremonies.

FASTI CONSULARES, a tablet or chronicle, wherein the ſeveral years were denoted by the reſpective conſuls, with the principal events that happened during their conſulſhip. And hence, the term faſti is ſtill applied to the archives and public regiſters of a nation.

FASTIGIUM, in architecture, the ſame with pediment. See PEDIMENT.

FAT, in anatomy, an oily, ſulphureous part of the blood, depoſited in the cells of the membrana adipoſa, from the innumerable little veſſels which are ſpread amongſt them.

This fat is to be found immediately under the ſkin, in all the parts of the body, except the forehead, eye-lids, lips, upper-part of the ear, penis, and ſcrotum. In ſome bodies the veſicles of the membrana adipoſa are ſo full, that the fat is an inch or more thick; and in others they are almoſt flat, containing little or no fat. There are two ſorts of fat, one white, or rather yellow, ſoft and lax, which is eaſily melted, and is called pinguedo; another white, firm, brittle, and which is not ſo eaſily melted, called ſebum, ſuet or tallow. Some reckon the marrow of the bones for a third ſort of fat.

Dr. Grew takes the fat of animals to be a curdling or coagulating of the oily parts of the blood, either by ſome of its own ſaline parts, or by the nitrous particles of the air mingled therewith: whence it is that ſome animals, as rabbits and field hares, grow fat in froſty weather: and for the ſame reaſon it is, that the fat of animals is hard; whereas that of fiſhes is ſoft, and runs all to oil, becauſe the water in which they live, hath but few nitrous particles in it, in compariſon of air.

FAT, or VAT, is alſo uſed for ſeveral utenſils, as, 1. A large wooden veſſel, uſed for the meaſuring of malt, and containing a quarter, or eight buſhels. 2. A large brewing veſſel, uſed by brewers to run their wort in. 3. A leaden pan or veſſel for the making of ſalt at Droitwich.

FAT likewiſe denotes an uncertain meaſure of capacity. Thus a fat of iſinglaſs contains from three hundred and a quarter to four hundred weight; a fat of unbound books, half a maund or four bales; of wine, from twenty to twenty-five hundred weight; and of yarn, from two hundred and twenty, to two hundred and twenty-one bundles.

FATE, or DESTINY, is ſomething that is ſuppoſed to infer the neceſſity of any event, the cauſe of which we are but very little acquainted with, and which ariſes from a power ſuperior to any that is ſubject to man.

The Stoics who admitted a providence, did, however, ſubject it to fate; and yet they did not make it more inflexible than the predeſtination of the Calviniſts.

FATHER, a term of relation denoting a perſon who hath begot a child.

FATHER, in theology, is uſed in ſpeaking of the firſt perſon of the Trinity. See the article TRINITY.

FATHER is alſo uſed in ſpeaking of ſpiritual and moral things. Thus Abraham is called the father of the faithful.

FATHER, in church hiſtory, is applied to ancient authors who have preſerved in their writings the tradition of the church.

FATHER is alſo a title of honour given to prelates and dignitaries of the church, to the ſuperiors of convents, to congregations of eccleſiaſtics, and to perſons venerable for their age and quality.

FATHER-LASHER, a name given by the inhabitants of Cornwall to a fiſh of the cottus kind, with the upper-jaw longeſt, and a prickly head.

FATNESS. See the article CORPULENCY.

FATTENNING of oxen, horſes, ſwine, poultry, &c. See the articles OX, HORSE, &c.

FAVIFORM, in general, ſomething reſembling a honey-comb. Surgeons give this appellation to certain ulcers, which emit a ſanies through little holes, eſpecially in the head. See HONEY-COMB.

FAUNALIA, in Roman antiquity, three annual feſtivals in honour of the god Faunus, the firſt of which was obſerved on the ides of February; the ſecond on the ſixteenth of the calends of March; and the third on the nones of December.

FAUNS, FAUNI, or SATYRS, were a kind of rural deities, or rather demi-gods, among the Romans, and inhabited the woods; wherefore they were called ſylvani; they were companions of Pan or Faunus. They were not known among the Greeks. The Latins repreſented them half man and half goat, with the horns, ears, feet, and tail of a goat, a flat noſe, and with hair on their bodies. The wild pine and olive were conſecrated to the Fauns. We find ſome authors ſo ridiculous as ſeriouſly to examine,

whether there were ſuch animals whoſe bodies were part man and part beaſt!

FAUSSE-BRAYE, in fortification, is a mount or rampart, of four fathoms width, on the outſide of the firſt rampart, that goes quite round the place, in order to defend the foſſe; and is covered with a parapet. It is made uſe of to fire upon the enemy, when advanced ſo far as not to be driven off the parapet from the body of the place; and it alſo ſerves to receive the ruins which the cannon make in the body of the place.

FAWN, among ſportſmen, a buck, or doe, of the firſt year; or the young one of the buck's breed in its firſt year.

FEALTY, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land: by this oath the tenant holds in the freeſt manner, on account that all who have fee, hold *per fidem et fiduciam*, that is, by fealty at the leaſt.

FEAST, or FESTIVAL, is applied now to any ſolemnity or feſtivity; but, in the church, it ſignifies thoſe days which are obſerved in honour of God, or of ſome ſaint.

According to Athenæus, feaſts were occaſioned by devotion to the gods; for though on feſtival days people reſted from their labour, and lived more plentifully than at other times, yet believing the gods were preſent at their tables, they behaved with ſobriety; neither did they drink to exceſs, but, after a moderate refreſhment, offered libations and ſo departed home. The Hebrews were very magnificent and expenſive in their feaſts, which they had frequently; where all was gaiety and mirth, and every thing that could delight the ſenſes was introduced. Sitting was their original poſture at meals, which they afterwards changed to lying on beds. The Greeks and Romans had a ſympoſiarch, or governor of the feaſt, whoſe office Plutarch deſcribes.

At Athens no perſon was allowed to entertain above thirty at once. Men and women were never feaſted together, as Cicero inform us, Orat. 3. in Verrem, wherein the Greeks differed from the Romans, amongſt whom women were allowed more freedom. Before people went to an entertainment, they anointed themſelves. They who came off a journey were waſhed and clothed in the houſe of the entertainment, before they were admitted to the feaſts. They were uſually clad in white, or ſome ſuch chearful colour; they waſhed their hands before they ſat down, and between every courſe, and after ſupper.

FEATHER, *Pluma*, the part which covers birds, and enables them to fly. See BIRD.

FEATHER, in horſemanſhip, a ſort of natural frizzling of the hair, which in ſome parts riſes above the reſt, reſembling the tip of an ear of corn. This happens moſt frequently between the eyes; and if lower, it is a ſign of a weak ſight.

A feather upon a horſe's neck, is called a Roman feather; being a row of hair turned back, and forming a mark like a ſword-blade near the mane.

Mid-FEATHER, in the ſalt-works, the partition in the middle of the furnace, which it divides into two chambers.

FEATHER-EDGED, among carpenters, an appellation given to planks or boards, which have one ſide thicker than the other.

Prince's FEATHER, a plant otherwiſe called amaranth. See the article AMARANTH.

FEBRIFUGES, in medicine, are ſuch things as mitigate or remove a fever; they are otherwiſe called antifebrilia.

The word is Latin, *febrifuga*, and derived from *febris*, a fever, and *fugo*, to remove, or drive away.

FEBRIS, FEVER, in medicine. See FEVER.

FEBRUARY, the ſecond month in the year, reckoning from January. It was added to Romulus's calendar by Numa Pompilius.

The word is Latin, *Februarius*, and derived from *februa*, which was a certain kind of ceremony performed in that month, in which wax candles and flambeaux were lighted at the graves of the dead, and oblations made to their manes.

FECIALES, or FOECIALES, a college of prieſts inſtituted at Rome by Numa, conſiſting of twenty perſons, ſelected out of the beſt families. Their buſineſs was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith.

FECULA, or FÆCULA, in pharmacy. See the article FÆCULA.

FECULENT, or FÆCULENT. See the article FÆCULENT.

FECUNDITY, or FOECUNDITY, the ſame with fertility. See the article FERTILITY.

FEE, in law, ſignifies a certain allowance to phyſicians, barriſters, attornies, and other officers, as a reward for their pains and labour.

FEE alſo denotes a ſettled perquiſite of public officers, payable by thoſe who employ them.

FEE-ESTATE, that held by the benefit of another, and for which ſome ſervice, rent, or acknowledgment is paid to the chief lord, or ſuperior, in whom the mere propriety of the ſoil always continues.

Fee is generally divided into abſolute and conſtitutional. Abſolute, otherwiſe termed fee-ſimple, is where a perſon is ſeized of lands or tenements, to him and his heirs for ever; whereas, fee-tail, or conditional fee, is where a perſon is ſeized of lands, with a limitation to him and the heirs of his body. A fee-ſimple is the largeſt eſtate a perſon can have, and can be conveyed by no other expreſſion, but heirs for ever; yet, in a will, which is more favoured than a grant, the intention of the teſtator is more conſidered than the literal meaning of the words.

FEE-FARM, a kind of tenure without homage, fealty, or other ſervice, except that mentioned in the feoffment; which is uſually the full rent, or at leaſt a fourth part of it.

The nature of this tenure is, that if the rent be behind, and unpaid for two years, then the feoffer and his heirs may have an action for the recovery of the lands.

FEELERS, in natural hiſtory, a name uſed by ſome for the horns of inſects. See the article HORN.

FEELING, TOUCHING, one of the external ſenſes, by which we attain the ideas of ſolid, hard, ſoft, rough, hot, cold, wet, dry, and other tangible qualities.

The feeling participates of leſs delicacy than the other ſenſes, but at the ſame time ſurpaſſes them in point of certainty. It abſolutely cuts off all incredulity; beſides which good property, it enjoys that of being the moſt general ſenſation. Seeing and hearing reſult from the organization of a very minute portion of our ſtructure; but it is requiſite that every part of the animal œconomy ſhould be endued with the faculty of feeling, to diſtinguiſh us from mere machines, that may be taken to pieces at pleaſure, without the conſciouſneſs of any violence offered to their mechaniſm. This is what nature has furniſhed; and wherever we find nerves and life, there alſo ſubſiſts this ſort of ſenſation; which does not ſeem to ſtand in need of any particular organization, or to depend on the ſtructure of the nervous papillæ, the ſimple ſolid texture of the nerve being alone ſufficient to produce it. The lips of a green wound, the perioſteum, or a tendon, laid bare, have a very quick ſenſation, though deſtitute of the nervous papillæ obſervable on the ſkin. Nature, whom one would conclude neceſſarily obliged to be at a great expence in producing this ſenſe of feeling, has, nevertheleſs, eſtabliſhed it at a ſmall one; ſo that the nervous papillæ are not abſolutely neceſſary to feeling, but to the perfection of it, and the variety of the reſpective ſenſations. The ſenſe of feeling, therefore, is the baſis of all other ſenſations: it is the genus of which they are the moſt perfect ſpecies. All the nervous ſolids, animated by a fluid, are endued with this general ſenſation. But the papillæ of the ſkin, thoſe of the fingers, for example, enjoy it to a degree of perfection, which adds to the firſt ſenſation a ſort of diſcernment of the figure of the body touched. The papillæ of the tongue ſurpaſs thoſe of the ſkin; and, in ſhort, thoſe of the noſe, the papillæ of the tongue: and ſo of the reſt, in proportion to the delicacy of the ſenſation. What we are advancing, in regard to the papillæ, does not at all exclude the reſt of the nervous texture from the ſhare it has in cauſing ſenſation. The papillæ are more concerned than this texture, in particular organs, as on the ſkin and the tongue. In others they have a leſs portion aſſigned them; namely, in reſpect of the

the noſe, or the pituitary membrane, which conſtitutes the organ of ſmelling. In ſhort, in other places, the papillæ ſeem to have ſtill a leſs ſhare; and the ſolid nervous texture almoſt ſingly compoſes the organ, as in the ſight. Theſe differences proceed from each organ's being proportioned to the object whoſe impreſſion it receives. It would be very conducive to the perfection of feeling, were the nerves to form ſmall ſenſible eminences; becauſe theſe ſort of ſharp-pointed ſubſtances are more eaſily irritated by the ſurface of bodies, than any uniform texture could poſſible be. The taſte would require nervous papillæ, that ſhould be of a ſpongy nature, and at the ſame time ſufficiently impregnated with moiſture, to dilute and diſſolve the principles of taſte, and to admit them eaſily into their texture, in order to their making a more lively impreſſion. The pituitary membrane that lines the organ of ſmelling, is furniſhed with ſoft, downy windings, and little cells, to confine the odoriferous vapours; but its object being ſubtile, it would have no occaſion either for papillæ or ſenſible points. The choroides, the immediate organ of ſight, has likewiſe its ſoft black down, to abſorb the images that make its object: but the bottom of theſe velvet ſubſtances, formed to receive the images, ought to be a nervous membrane very ſmooth and ſenſible.

All matter, of ſufficient conſiſtence or ſolidity to affect the ſurface of our ſkin, becomes the object of feeling. This ſenſe aſcertains the bulk and figure of bodies, their diſtance, inaction, motion, ſolidity, ſoftneſs, fluidity, heat, coldneſs, dryneſs, moiſture, &c. theſe are its proper objects.

The ſenſation of warmth or heat is a ſort of light emotion, or irritation of our nervous parts, and an expanſion of our ſolids and fluids, produced by the ſlight action of a moderate quantity of the ſubtile matter that compoſes fire, or the origin of heat, whether natural or artificial.

When this matter either exceeds in quantity, or is more than ordinarily agitated, then, inſtead of irritating or expanding our ſolids and fluids, it tears and diſſolves them; and this violence of action cauſes an inflammation.

The ſenſation of cold, on the contrary, is a ſort of obſtruction in the nervous papillæ, and generally in all the ſolids, and a condenſation or defect of motion in our fluids, ariſing either from the contact of ſome cold ſubſtance; that is to ſay, of a ſubſtance that is not to any degree impregnated with ſubtile agitated matter, like the air or water; or by any other accidental cauſe, whereby the motion of our fluids, and natural elemental heat, is ſuppreſſed, like the periodical convulſion of the ſolids that produces the ſhivering in an ague. It is probable that our fluids being either totally condenſed, or impeded in their motion, by one or other of theſe cauſes, the nervous papillæ, and the ſolids in general, which are ſolely expanded by the impulſe of theſe fluids, are immediately blocked up; and it is this conſtipation that is the ſource of all the effects of cold in the human body.

The ſkin, the organ of feeling, is a compoſition of fibres, nerves, and veſſels, which are interwoven one with the other in ſuch an extraordinary manner, that the texture, in ſome meaſure, reſembles net-work. See CUTIS.

This fibrous texture is viſible in thick ſhammy, and in the ſoles of ſhoes made of a thick and ſoft leather, where, indeed, the fibres appear very diſtinctly.

The ſkin adheres to all the parts it incloſes, by means of blood-veſſels, lymphatics, nerves, and ſometimes fleſhy fibres, as in the face; but commonly by ſeveral very thin complicated foliages, which form themſelves into little cells, where the extremities of the arteries ſecrete an oil, termed fat. The anatomiſts call theſe ſtrata of foliages the cellular membrane, or membrana adipoſa.

The ſkin is formed of all the parts themſelves that faſten it to the body which it infolds. Theſe foliages, veſſels, and capillary nerves are determined one over the other by the compreſſion of the waters that ſurround the fœtus in the womb, and after its birth by the preſſure of the atmoſphere. Theſe fibres, being thus interwoven and preſſed together, form the ſubſtance we have been deſcribing. Several of theſe veſſels, originally hollow, acquire, in a ſhort ſpace, a firm ſolidity, and become, as it were, tendinous; and are, with the nerves, the principal ſubſtance of this thick texture.

The nervous capillaries, after having concurred, by thin twining and running acroſs one another, to the formation of the ſkin, terminate in its external ſurface, where they ſhed their firſt coat, to wit, that ſupplied by the dura mater. This firſt coat, commonly ſtiled the ſheath of the nerve, is divided into ſeveral ſhreds, that ſtick entangled together on the ſurface of the ſkin, and by that means conſtitute a ſort of net-work, called the reticulary body.

The mechaniſm of this nervous net-work is very well accommodated for receiving the impreſſion of objects; but the extremity of the nerve, ſtripped of this firſt coat, expands and raiſes itſelf between the interſtices of this net-work, and forms the nervous papillæ. Theſe are elevated above the net-work, are far more ſuſceptible of irritation, and conſequently entirely formed for the production of the moſt perfect ſenſation. A ſpirituous lymph moiſtens theſe papillæ, renders them ſuple and elaſtic, and of courſe furniſhes an organ, in all reſpects complete and accompliſhed.

Theſe papillæ are ranged in lines, and in a certain order: and it is this order that produces the little ridges obſervable on the cuticle or ſcarf-ſkin, and ſo viſible at the ends of our fingers, where they are ſpiral.

The nervous papillæ are perpendicular to the ſurface of the body. At the ends of the fingers they are lengthened in proportion to the extent of that part, and are ſo cloſely connected together, as to form thoſe ſolid bodies, the nails.

Their very ſtraight union is the reaſon why there is no paſſage for the animal fluid through this compoſition, whence the nail becomes inſenſible. But to make amends, at the root of the nail, where the nervous papillæ are very ſolid, very elaſtic, and remain open to the flux of ſpirits, the ſenſation is extreme. The ſanguinary, lymphatic, and oily capillaries, that penetrate the texture of the ſkin, are diſtributed almoſt like the nerves: being interwoven one with another in the ſkin, they form the vaſculary net-work. Their expanſion on the ſurface of the ſkin conſtitutes the excretory veſſels, and the cuticle that inveſts the papillæ, and is very neceſſary to them, by ſoftening the impreſſion of objects, and rendering by that means the perception more diſtinct. In ſhort, to this ſtructure, ſo adapted to forming the organ of feeling, we muſt add the glands ſituated under the ſkin; which ſerve to ſupply, at the end of the lymphatics, the ſpirits neceſſary for the lymph that moiſtens the nervous papillæ, and to beſtow on the animal fluid a preparation requiſite to the perfection of this ſenſation.

FEINT, in muſic, the ſame with dieſis. See the article DIESIS.

FEINT, in fencing, a ſhew of making a thruſt at one part, in order to deceive the enemy, that you may really ſtrike him in another.

A ſimple feint is a mere motion of the wriſt, without ſtirring the foot.

FELAPTON, in logic, one of the ſix moods of the third figure of ſyllogiſms, wherein the firſt propoſition is an univerſal negative, the ſecond an univerſal affirmative, and the third a particular negative.

FELIS, in zoology, is uſed by Linnæus as the name of a large genus of quadrupeds, of the order of the feræ; the characters of which are theſe: the fore-teeth are ſmall, obtuſe, and equal; the tongue is furniſhed with prickles, all pointing backwards; and the feet are formed for climbing, with claws which may be drawn in or extended at the creature's pleaſure.

To this genus belong the lion, tiger, leopard, cat, cat of the mountain, lynx, and ounce.

FELLING *of Timber*.—Many circumſtances are well known and conſtantly obſerved in the felling of timber for building, which, though to a haſty obſerver they might appear trifling, yet prove, on experience, to be of the utmoſt conſequence. One thing obſerved by Mr. De Buffon, which very greatly increaſes the ſolidity and ſtrength of timber, is, that the trees intended to be felled for ſervice ſhould firſt be ſtripped round of their bark, and ſuffered to ſtand and die upon the ſpot before the cutting. The ſappy part, or blea of the oak, becomes

by

by this means as hard and firm as the heart, and the real ſtrength and denſity of the wood has been proved, by many experiments, to be greatly increaſed by it; nor is this a practice of any detriment to the proprietor, ſince the remaining ſtumps of theſe trees ſend up their young ſhoots as vigorouſly as if they had been cut down in their natural condition.

When any tree is to be cut down for timber, the firſt thing to be taken care of is a ſkilful diſbranching ſuch limbs as may endanger in its fall: many trees are utterly ſpoiled for want of a previous care of this kind. In arms of timber that are very great, it is always neceſſary to chop or ſink in them cloſe to the bole, and then, meeting it with down-right ſtrokes, it will be ſevered from the tree without ſplitting. In felling the tree, take care always to cut it as cloſe to the ground as poſſible, unleſs it is intended to be grubbed up; and the doing this is of advantage both to the timber, and to the wood; for timber is never ſo much valued, if it be known to grow out of old ſtocks.

FELLOWSHIP, COMPANY, or PARTNERSHIP, in arithmetic, is a rule of great uſe in balancing the accounts of ſeveral partners trading in a company, ſo that every partner may have his juſt part of the gain, or ſuſtain his juſt part of the loſs, according to his proportion or ſhare of money he hath in the joint ſtock: this falls under two conſiderations, called the *Single* and *Double Rule of* FELLOWSHIP.

Single FELLOWSHIP, or FELLOWSHIP *without Time*.—By this rule are adjuſted the accounts of thoſe partners that put all their ſeveral, and perhaps different, ſums of money into a common ſtock at one and the ſame time; and therefore it is uſually called the Rule of Fellowſhip without Time: queſtions of this nature are anſwered by ſo many ſeveral operations in the Rule of Three direct, as there are partners in the ſtock.

Example 1. Suppoſe three partners, A, B, and C, make a joint ſtock of 192 *l.* in this manner: A puts in 48 *l.* B puts in 64 *l.* and C puts in 80 *l.* with this 192 *l.* they trade and gain 24 *l.* it is required to find each man's true part of that gain?

Here it will be as the ſum of the ſtocks 192 *l.* is to the total gain 24 *l.* ſo is each man's particular ſtock to his reſpective ſhare of the total gain: wherefore in this caſe A's ſhare of the gain will be 6 *l.* B's 8 *l.* and C's 10 *l.*

Proof. 6 *l.* + 8 *l.* + 10 *l.* = 24 *l.* the whole gain.

That is, if the ſum of each man's particular gain amount to the whole gain, the work is true; if not, ſome error is committed which muſt be found out.

Examp. 2. Three merchants A, B, and C, freight a ſhip with 248 tuns of wine; A loaded 98 tuns; B 86 tuns; and C 64 tuns. By extremity of weather the ſeamen were forced to caſt or throw 93 tuns of it overboard, How much of this loſs muſt each merchant ſuſtain?

	98	36,75	for A's loſs.
As 248 is to 93 ſo is	86	to 32,25	for B's loſs.
	64	24,00	for C's loſs.
Proof — — — —		93,00	= to the whole loſs.

Now, if the queſtion were, to find how much of the remaining wine that was ſaved belongs to A, to B, and to C?

Then 98 − 36,75 = 61,25 belongs to A.
And 86 − 32,25 = 53,75 belongs to B.
And 64 − 24, = 40 belongs to C.

That is, A ought to have 61 tuns and 63 gallons; B ought to have 53 tuns and 189 gallons; and C ought to have 40 tuns of what was left.

Double FELLOWSHIP, or FELLOWSHIP *with Time*.—This is uſually called the Double Rule of Fellowſhip, becauſe any particular man's money is to be conſidered, with relation to the time of its continuance in the joint ſtock.

Example 1. A and B join in partnerſhip upon theſe terms, viz. A agrees to lay down 100 *l.* and to employ it in trade three months; then B is to laydown his 100 *l.* and with the whole ſtock of 200 *l.* they are to trade three months more. Now, at the end of this time, they find their whole gain to be 21 *l.* it is required to know what each man's part of the gain ought to be, according to his ſtock, and the time of employing it?

Here it is but reaſonable to conclude that, as the ſum laid down by each perſon is the ſame, their reſpective gains ſhould be in the proportion of the times thoſe equal ſums were employed; conſequently as 9, the ſum of the times, is 3 B's time, ſo is the whole gain 21 *l.* to 7 *l.* B's ſhare of the gain, which taken from 21 *l.* leaves 14 *l.* for the ſhare of A.

If in the above example the times had been equal, but the ſums laid down unequal, it is evident the whole gain in that caſe muſt have been divided between the partners in the ratio of the ſums adventured; whence it follows, that when the ſtocks and times of continuance are reſpectively unequal, the total gain muſt be divided in the ratio compounded of each man's money and time reſpectively. Therefore, in order to reſolve all queſtions of this nature, be the partners never ſo many, obſerve this rule.

Multiply every particular man's ſtock, with the time it is employed; then it will be as the ſum of all theſe products is to the whole gain or loſs; ſo is every one of theſe products to its proportional part of that whole gain or loſs.

Examp. 2. Three merchants, A, B, and C, enter into partnerſhip, thus; A puts into the ſtock 65 *l.* for eight months, B puts in 78 *l.* for twelve months, and C puts in 84 *l.* for ſix months; with theſe they traffic and gain 166 *l.* 12 *s.* it is required to find each man's ſhare of the gain proportionable to his ſtock and time of employing it?

1. A's ſtock 65 *l.* × 8 mon. the time it was employed = 520
2. B's ſtock 78 *l.* × 12 mon. the time it was employed = 936
3. C's ſtock 84 *l.* × 6 mon. the time it was employed = 504

The ſum of theſe products — — — — 1960

Then, according to the rule, the ſeveral proportions will ſtand thus:

1960 : 166,6 :: 520 : 44,2 =	44 *l.*	4 *s.*	0 *d.*	for A.
1960 : 166,6 :: 936 : 79,56 =	79	11	2 ½	for B.
1960 : 166,6 :: 504 : 42,84 =	42	16	9 ½	for C.
The whole gain — —	166	12	0	

Or you may work by firſt finding the proportional part of the gain due to one pound, which will ſerve for a common multiplier.

Thus 1960 : 166,6 :: 1 : 0,085, the ſaid common multiplier.

Then 520 × 0,085 = 44,2 for A.
And 936 × 0,085 = 79,56 for B. } as before.
Alſo 504 × 0,085 = 42,84 for C.

FELO DE SE, in law, a perſon that deliberately lays violent hands on himſelf, and is the occaſion of his untimely death, whether by hanging, drowning, ſtabbing, ſhooting, or any other way.

FELON, in law, a perſon guilty of felony.

FELON-WORT, in botany, the ſame with the ſolanum, or deadly night-ſhade.

FELONY, in law, a capital crime, next in degree to petit treaſon, and committed with an evil intention; as murder, theft, ſodomy, rape, ſetting fire to houſes wilfully, &c.

FELT, in commerce, a kind of ſtuff, compoſed either of wool alone, or of a mixture of wool and hair; but neither ſpun nor wove, deriving all its conſiſtence from being fulled, or wrought, with lees and ſize.

FEMALE, a term peculiar to animals, and ſignifies that ſex which conceives and generates its young within itſelf.

The word is alſo applied, in a figurative ſenſe, to inanimate objects, from the reſemblance they bear to the female of animals: thus we ſay, a female ſcrew, a female flower, &c. See FLOWER, SCREW, &c.

FEMME COVERT, in law, a married woman. See COVERTURE.

FEMME SOLE, an unmarried woman, whoſe debts, contracted before marriage, become thoſe of her huſband after that ceremony has been performed.

FEMININE, in grammar, is that gender which denotes a female.

FEMUS, the thigh, in anatomy, is that part of the body intercepted between the buttocks and the knee. See the article THIGH.

FEN,

FEN, a general name for boggy or marſhy land, commonly overflowed with water.

In draining theſe ſort of lands, which is the only method of making them uſeful, trenches and drains for carrying off the water muſt be formed, in order to render the ſurface dry, and of a proper conſiſtence for producing vegetables.

This may be attempted by various methods; but whatever mode of proceeding be adapted, the loweſt part of the ground is to be found out firſt, and the overflowing from great rains, and from land floods, muſt be provided for, in the carrying off that way; for, ſhould this be neglected, all the labour and coſt employed on the other principle would be thrown away. If it is found that this can be done, there muſt be afterwards cut a large drain through the middle of the land, and ſeveral ſmaller drains communicating with this.

The great drain muſt be dug deep enough to drain the whole level; and this, and all the others, muſt be made the narroweſt at the head, and wider all the way to the mouth, where it muſt be wideſt of all.

Theſe drains muſt be all well cleanſed from mud and weeds every ſpring and autumn, and the water from land-floods muſt be kept from coming in upon theſe lands, as much as poſſible, that there may be the leſs to be drained off; the lower edges of the ſen-land muſt be for this purpoſe guarded with banks to turn the water into other channels. In Eſſex, they have many lands that lie below the high-water mark, and are above the low-water mark, and have land-floods or fleets running through them, which make a ſort of ſmall creek. Theſe lands they have a very eaſy way of draining, though they are naturally very moiſt, when they firſt incloſe them from the ſea; they do it with a bank, which they extend from one ſide of the land they deſign to take in, to the other, excepting a ſpace that they leave, where the creek or land-floods run into the ſea. They then prepare a wooden frame, well planked, and of a conſiderable thickneſs, fitted to the head of the creek, and capable of ſhutting it wholly up; in this frame they make ſeveral holes, in which are placed wooden troughs, made each of four boards, and ſuited in ſize and number to the quantity of water that is to be diſcharged through them from the land-floods. Each of theſe trunks is open towards the creek, but on the ſea-ſide it has a door or flap, which opens when the land-flood preſſes againſt it, and gives it free paſſage out; but, when the ſea-water is riſen to the height of it and preſſes it, it is ſhut by the force, and no ſea water is let in. When this head is prepared, they let it in, and, ſtopping up the whole creek, they continue the banks on each ſide till they meet it: thus all the land-floods are let out at low water, and not a drop of ſea water can be admitted, ſo that the lands are kept dry and uſeful, which were before rendered uſeleſs, by being drowned with ſalt water at every high-water mark. The freſh water of the creek is thus kept unmixed with the ſea water, and therefore affords good drink for the cattle, which is commonly very difficult to be had in this ſort of lands, the tides ſpoiling what freſh waters there are, every time they come up.

The wet grounds, called fens, in Lincolnſhire and elſewhere in England, bring many advantages to the inhabitants of thoſe countries. Fowl and fiſh are very plentiful in them. The pike and eels are large, and eaſily caught, but they are uſually coarſe. The duck, mallard, and teal are in ſuch plenty, as is ſcarce to be conceived; they are taken in decoys, by prodigious flocks at a time. They ſend theſe fowl to London from Lincolnſhire, twice a week on horſe-back, from Michaelmas to Lady-day, and one decoy will furniſh twenty dozen, or more, twice a week, for the whole ſeaſon, in this manner. The decoy-men contract with the people who bring them to London at a certain rate, and they are obliged to take the whole number that is catched off their hands. Two teal are uſually reckoned equal to one duck, and ſix ducks and twelve teal are accounted a dozen of wild-fowl; and the uſual market price is about nine ſhillings for ſuch a dozen. About Midſummer, when the moulting ſeaſon is, a great number are deſtroyed alſo by the people of the neighbourhoods. The poor birds at this time are neither able to ſwim nor to fly well; and the people going in with boats among the reeds, where they lie, beat them down with long poles.

A little before Michaelmas, vaſt flights of theſe birds arrive at the decoys from other places; they ſoon grow fat in them, and continue there a prey to the maſters or owners, as long as the decoys are unfrozen; but, when they are iced over, they fly away again, and go to the neighbouring ſeas for food. *Philoſ. Tranſ.* N°. 223.

FENCE, in gardening and huſbandry, a hedge, wall, ditch, bank, or other incloſure, made round gardens, fields, woods, &c.

In hotter climates than England, where they have not occaſion for walls to ripen their fruit, their gardens lie open, where they can have a water fence, and proſpects; or elſe they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleaſing to the ſight than a dead wall: but in colder countries, and in England, we are obliged to have walls to ſhelter and ripen our fruit, although they take away much from the pleaſant proſpect of the garden.

Since therefore we are under a neceſſity to have walls to ſecure our gardens from the injury of winds, as well as for the convenience of partitions or incloſures, and alſo to ripen our fruit, brick walls are accounted the beſt and warmeſt for fruit: and theſe walls, being built panel-wiſe, with pillars at equal diſtances, will ſave a great deal of charge, in that the walls may be built thinner than if they were built plain without theſe panels; for then it would be neceſſary to build them thicker every-where; and, beſides, theſe panels make the walls look the handſomer.

Stone walls are to be preferred to thoſe of brick, eſpecially thoſe of ſquare hewn ſtones. Thoſe that are made of rough ſtones, though they are very dry and warm, yet, by reaſon of their unevenneſs, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there for that purpoſe.

But in large gardens it is better to have the proſpect open to the pleaſure garden; which ſhould be ſurrounded with a foſſe, that from the garden the adjacent country may be viewed; but this muſt depend on the ſituation of the place: for, if the proſpect from the garden is not good, it had better be ſhut out from the ſight by a wall, or any other fence, than to be open. As alſo, when a garden lies near a populous town, and the adjoining grounds are open to the inhabitants; if the garden is open, there will be no walking there in good weather, without being expoſed to the views of all paſſengers, which is very diſagreeable.

Where the foſſes are made round a garden which is ſituated in a park, they are extremely proper; becauſe hereby the proſpect of the park will be obtained in the garden, which renders thoſe gardens much more agreeable than thoſe which are confined.

In the making theſe foſſes there have been many inventions; but, upon the whole, I have not ſeen any which are in all reſpects preferable to thoſe which have an upright wall next the garden, which (where the ſoil will admit of a deep trench) ſhould be five or ſix feet high; and, from the foot of this wall, the ground on the outſide ſhould riſe with a gradual eaſy ſlope, to the diſtance of eighteen or twenty feet; and where it can be allowed, if it ſlopes much farther, it will be eaſier, and leſs perceptible as a ditch to the eye, when viewed at a diſtance: but, if the ground is naturally wet, ſo as not to admit a deep foſſe, then, in order to make a fence againſt cattle, if the wall be four feet high, and ſlight poſts of three feet high are placed juſt behind the wall, with a ſmall chain carried on from poſt to poſt, no cattle or deer will ever attempt to jump againſt it: therefore it will be a ſecure fence againſt them; and, if theſe are painted green, they will not be diſcerned at a diſtance, and at the ſame time the chain will ſecure perſons walking in the garden from tumbling over.

In ſuch places where there are no good proſpects to be obtained from a garden, it is common to make the incloſure of park-paleing; which, if well performed, will laſt many years, and has a much better appearance than a wall: and this pale may be hid from the ſight within, by plantations of ſhrubs and ever-greens; or there may be a

quick hedge planted within the pale, which may be trained up, ſo as to be an excellent fence by the time the pales begin to decay.

There are ſome perſons who make ſtuckade fences round their gardens to keep out cattle, &c. which, when well made, will anſwer the purpoſe of fences; but this being very expenſive in the making, and not of very long duration, has occaſioned their not being more commonly in uſe.

As to fences round parks, they are generally of paling; which, if well made of winter-fallen oak, will laſt many years; but a principal thing to be obſerved, in making theſe pales, is not to make them too heavy; for, when they are ſo, their own weight will cauſe them to decay; therefore the pales ſhould be cleft thin, and the rails ſhould be cut triangular, to prevent the wet lodging upon them; and the poſts ſhould be good, and not placed too far aſunder. If theſe things are obſerved, one of theſe pales will laſt, with a little care, upwards of forty years very well. The common way of making theſe fences is, to have every other pale nine or ten inches above the intermediate ones; ſo that the fence may be ſix feet and a half high, which is enough for fallow deer; but, where there are red deer, the fence ſhould be one foot higher, otherwiſe they will leap over.

Some incloſe their parks with brick walls; and in countries, where ſtone is cheap, the walls are built with this material; ſome with, and others without mortar.

A kitchen garden, if rightly contrived, will contain walling enough to afford a ſupply of ſuch fruits as require the aſſiſtance of walls for any family; and this garden, being ſituated on one ſide, and quite out of ſight of the houſe, may be ſurrounded with walls, which will ſcreen the kitchen garden from the ſight of perſons in the pleaſure garden; and, being locked up, the fruit will be much better preſerved than it can be in the public garden: and the having too great a quantity of walling is often the occaſion that ſo many ſcandalous trees are frequently to be ſeen in large gardens, where there is not due care obſerved in their management.

The height of garden walls ſhould be twelve feet, which is a moderate proportion; and, if the ſoil be good, it may in time be well furniſhed with bearing wood in every part, eſpecially that part planted with pears, notwithſtanding the branches being trained horizontally from the bottom of the walls.

I would recommend the white thorn, the holly, the black thorn, and crab, for outward fences to a good ground: but I do not approve of the intermixing them.

The white thorn is the beſt quick to plant; becauſe it is the moſt common, and may be clipped ſo as to render it the cloſeſt and the hardieſt fence of any other tree; and, being very durable, is preferred to all others for outward fences; or for the diviſion of fields, where they are expoſed to cattle, &c.

The black thorn, and crabs, make very good fences, and are to be raiſed as the white thorn; but, if the kernels of apples or crabs be ſown, it is beſt to ſow the pommace with them, and they will come up the ſooner, i. e. the firſt year.

If crab ſtocks be planted, while young, in the ſame manner as quick, they make excellent hedges; and ſo will ſome ſorts of plumbs.

The holly will make an excellent fence, and is preferable to all the reſt; but it is difficult to be made to grow at firſt, and is a ſlow grower; but when once it does grow, it makes amends by its height, ſtrength, and thickneſs. *Miller's Gard. Dict.*

FENCE-MONTH, the month wherein deer begin to fawn, during which it is unlawful to hunt in the foreſt.

It commences fifteen days before Midſummer, and ends fifteen days after it. This month, by ancient foreſters, is called defence-month. There are alſo certain fence-months, or ſeaſons, for fiſh as well as wild beaſts, as appears by Stat. Weſt. 13 Geo. II.

FENCING, the art of making a proper uſe of the ſword, as well for attacking an enemy, as for defending one's ſelf.

Fencing is a genteel exerciſe, of which no gentleman ought to be ignorant. It is learned by practiſing with foils, called in Latins, *rudes*. See FOIL.

According to Pyraid, fencing is in ſo high repute in the Eaſt-Indies, that the greateſt noblemen, and even princes, teach it.

Fencing is either ſimple or compound. Simple is that performed nimbly and off hand, on the ſame line. In this the principal intention, in reſpect to the offenſive part, ſhould be to attack the enemy in the moſt unguarded part; and in the defenſive, to parry or ward off the enemy's thruſts and blows. See the articles GUARD, THRUST, PARRYING, &c.

FENDERS, among ſailors, certain pieces of rope, wood, faggots, or other material, hung over the ſide of a ſhip or boat to prevent them from ſtriking or rubbing againſt each other, when they lie cloſe together; alſo to prevent ſhips, boats, and other veſſels from beating againſt a wharf or key.

FENDUE *en Pal*, in heraldry, a croſs clove down in pale, that is, from top to bottom, and the two parts ſet at ſome diſtance from each other.

FENESTRA, in anatomy, a term applied to two openings or foramina within the ear, diſtinguiſhed by the names of the oval and the round feneſtra.

FENNEL, *ſæniculum*, in botany. See FOENICULUM.

FENUGREEK, or FOENUGREEK. See FOENUGREEK.

FEOFFMENT, in law, is a gift or grant of any manors, meſſuages, lands, or tenements, to another in fee, that is, to him and his heirs for ever, by delivery of ſeiſin, and poſſeſſion of the eſtate granted.

FERALIA, in antiquity, a feſtival obſerved amongſt the Romans, on the twenty-firſt of February; or, according to Ovid, on the ſeventeenth of that month, in honour of the manes of their deceaſed friends and relations.

FER DE FOURCHETTE, in heraldry, a croſs having at each end a forked iron, like that formerly uſed by ſoldiers to reſt their muſkets on. It differs from the croſs fourché, the ends of which turn forked, whereas this has that ſort of fork fixed upon the ſquare end.

FER DE MOULIN, *Milrinde*, *Inke de Moulin*, in heraldry, is a bearing ſuppoſed to repreſent the iron-ink or ink of a mill, which ſuſtains the moving mill-ſtone.

FERIÆ, in Roman antiquity, holidays, or days upon which they abſtained from work.

FERIAL DAYS, according to the Statute 27 Henry VI. cap. v. are taken for all days of the week except Sunday.

FERMENT, any body which, being applied to another, produces fermentation.

Ferments are either matters already in the act of fermentation, or that ſoon run into this act. Of the firſt kind are the flowers of wine, yeaſt, fermenting beer, or fermenting wine, &c. and of the ſecond are the new expreſſed vegetable juices of ſummer fruits.

Among diſtillers, ferments are all thoſe bodies which, when added to the liquor, only correct ſome fault therein, and by removing ſome obſtacle to fermentation, forward it by ſecondary means; as alſo ſuch as being added in time of fermentation, make the liquor yield a larger proportion of ſpirit, and give it a finer flavour. See the article ADDITION.

FERMENTATION, the inteſtine motion excited in vegetables, by which they are changed in ſuch a manner, that the firſt thing that riſes from them in diſtillation is acrid, mixible with water, of a warm aromatic taſte, inflammable like oil, thin and volatile; or elſe acid, that will extinguiſh fire and flame, and is leſs thin and volatile.

The word is Latin, *fermentatio*, and derived from *fermentum*, leaven.

A certain degree of warmth ſeems requiſite, in the northern climates, to all artificial liquors intended for immediate fermentation, eſpecially in the winter: but the natural juices of vegetables that have never been inſpiſſated, as that of grapes, and other fruits, when fully ripened, will uſually ferment as ſoon as they are expreſſed, without any external aſſiſtance. But as a certain degree of inſpiſſation

ſpiſſation prevents all tendency to fermentation in vegetable juices, otherwiſe ſtrongly diſpoſed to ferment; ſo a long continuance or increaſe of the inſpiſſating heat, eſpecially if it acts immediately, through a metalline or ſolid body, upon the juice, will deſtroy its fermenting property; and this the more effectually, as the heat employed approaches to that of ſcorching, or the degree capable of giving an empyreuma. After the ſame manner, ſeveral experiments make it appear, that there is a certain degree of heat, the continuance, or leaſt increaſe whereof, proves detrimental, or deſtructive to fermentation, as there is another that wonderfully encourages and promotes it. Theſe two degrees of heat ought to be carefully noted and ſettled by the thermometer, or other more certain method, for philoſophical and chemical uſes; but for common or œconomical occaſions, they may be limited to what we uſually underſtand by a tepid and a fervid heat: a fervid heat is the bane of all vinous fermentation; as a tepid one, or rather an imperceptible warmth, is the great promoter thereof. In this neutral ſtate therefore, with proper contrivances to preſerve and continue it, the liquor is to be put into a ſuitable veſſel for fermentation; at which time, if it work not of itſelf, it muſt be quickened by additions; and, in general, by ſuch things as are properly called ferments. See FERMENT.

When thus the proper quantity of a good-conditioned and ſuitable ferment is got ready, it muſt be put to the fermentable liquor in the bare tepid, or ſcarce luke-warm ſtate above-mentioned. The beſt manner of bringing them together, for raiſing the fermentation quick and ſtrong, ſeems to be this: when the ferment is ſolid, it ſhould be broke into ſmall pieces, and gently thinned, with the hand, or otherwiſe, in a little of the luke-warm liquor: but a complete uniform ſolution ſhould not be here endeavoured, becauſe this would in ſome meaſure weaken the power of the ferment, or deſtroy its future efficacy. The whole intended quantity therefore, being thus looſely mixed with a moderate quantity of the liquor, ſhould be kept in a tepid ſtate, free from the action of the external air; and at proper intervals more of the warm liquor ſhould be added, till the whole quantity is well ſet to work together: and thus, by dividing the buſineſs into parts, it may be much more ſpeedily and effectually performed.

FERMENTED, in general, ſomething that has undergone a fermentation. See the preceding article.

FERN, *Filix*, in botany. There are great varieties of this plant, in different parts of the world; but we ſhall only mention two ſpecies, the male and the female.

The leaf of the male fern is compoſed of other leaves, which adhere to a rib in ſuch a manner, as to have lobes on both ſides, cut into the depth of the main fibre: the fruit reſembles that of polypody.

The common female fern, or brakes, has many large leaves divided into ſeveral branches, beſet with long, narrow, ſtiff pinnulæ, which are moſtly ſmooth about the edges, though ſometimes they are a little indented: the back of theſe, about Midſummer, will be covered round the margins with a great number of duſky brown particles, which are the ſeed.

The ſeeds of the ſeveral ſpecies of fern were wholly unknown to the ancients. Swammerdam, in his Biblia Naturæ, claims to himſelf the honour of having firſt diſcovered them; but it appears from Hook's works, that Dr. William Cole ſent an account of the ſeeds of ſeveral of the plants of this kind to that author, in 1669; whereas Swammerdam declares his diſcovery of them to have been in 1673; ſo that it is plain that Dr. Cole's was prior to his by ſome years. Swammerdam is an author of that ſtrict probity, that there is no room to doubt but that he ſpoke what he thought to be true; and it is even poſſible that he might have diſcovered them ſooner than the time he mentions; but, however that be, it appears from the later obſervations of the ingenious Dr. Miles, that his accounts are extremely accurate and juſt. The ſeed-veſſels of the common fern, the Engliſh and foreign maiden-hairs, the wall-rue, hart's-tongue, and the like plants, are all alike in their general form, their only differences being in the ſize, and their arrangement on the plants. The number or quantity of the ſeeds is very different in different plants; but Dr. Miles obſerves, that, the fewer ſeeds there are in any ſpecies, there is always the more in quantity of a ſort of ſpongy or fungous matter, which forms a kind of tubercle, not unaptly reſembling what is called Jew's-ears, which ſeems a ſubſtance intended for the ſheltering the ſeeds.

Theſe ſeed-veſſels conſiſt of a ſtalk, by which they are inſerted into the leaf; this repreſents an elaſtic cord, and is ſurrounded by a great number of annular ribs, reſembling the cartilages of the aſpera arteria; and indeed nothing in nature ſo exactly reſembles this cord or ſtalk, as the wind-pipe of a ſmall bird. This cord incircles the globular membranous pod, wherein the ſeeds lie, adhering to it, and dividing it into two hemiſpheres.

The pod is compoſed of a fine whitiſh membrane, ſomewhat like that which lines the inſide of a pea-ſhell; the ſeeds are irregular in ſhape, and of a reticulated ſurface. The moſt advantageous way of viewing this is to uſe the common microſcope for opake objects, puttling on a ſmall magnifier, and laying the ſeeds with their capſules, &c. as taken from the back of the plant, on a piece of poliſhed ivory. The proper time of the year is in the beginning of September; and then, if the plant be newly gathered, the ſeed-veſſels often burſt, while they are under inſpection, and ſhew a very elegant appearance. The manner of this burſting of the pod, which is the method nature has taken for the ſcattering and diſperſing of the ſeed, is this: the cord becomes extended in ſome one part, and ſoon after breaks aſunder; this by expanding burſts the pod into two parts, and, continuing to expand itſelf, as it departs from a curve, and approaches to a right line, it rends itſelf away from the globular pod, till it be at length wholly diſengaged from it; and then, as there can be no farther reſiſtance given to its expanding, it ſuddenly flies off, with a ſort of jerk, and becomes quite ſtraight at once. By this laſt action the capſules are ſhook, and the ſeeds are diſcharged out of them on the plate of ivory, in the ſame manner as the grains of wheat or barley would be thrown out of a bowl placed on a table by the ſhaking of the bowl.

FERN *Oil*, in pottery, a name given, by the Engliſh merchants who have been in China, to a ſort of varniſh, which the Chineſe uſe in their porcelain manufactories. See CHINA.

FERRET, *Viverra*, in zoology, a quadruped of the muſtela kind.

The head is ſmall and depreſſed; the ſnout ſharp; the eyes look very fierce and red; the ears are ſhort, patulous, and erect, they are conſiderably wide, eſpecially towards the baſe; the mouth is large, and the teeth are very ſharp; the neck is ſhort; the body is long and thin; the legs are ſhort, and each divided at the foot into five toes, and there armed with ſharp claws. This animal is very common in England, but is a native of America.

FERRETS, in glaſs-making, the iron with which the workman tries the melted metal to ſee if it be fit to work.

It is alſo uſed for thoſe irons which make the ring at the neck of bottles. *Neri's Art of Glaſs.*

FERRETTO, in the glaſs trade, a ſubſtance which ſerves to colour glaſs. This is made by a ſimple calcination of copper, but it ſerves for ſeveral colours. There are two ways of making this; the firſt is this: take thin plates of copper, and lay them on a layer of powdered brimſtone, in the bottom of a crucible; over theſe lay more brimſtone, and over that another layer of the plates, and ſo on alternately, till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a ſtrong fire about it for two hours. When it is taken out and cooled, the copper will be found ſo calcined, that it may be crumbled to pieces between the fingers, like a friable earth; it will be of a reddiſh, and in ſome parts a blackiſh colour. This muſt be powdered and ſifted fine for uſe.

The other way is leſs eaſy, but it makes a more valuable ferretto. It is this: make a number of ſtratifications of plates of copper and powdered vitriol alternately in a crucible, which place in the floor of the glaſs furnace, near the eye, and let it ſtand there three days; then take it out, and make a new ſtratification with more freſh vitriol,

triol, and calcine it again as before; repeat this operation ſix times, and a moſt valuable ferretto is produced. *Neri's Art of Glaſs.*

FERRUGINOUS, any thing partaking of iron, or that contains particles of that metal. It is particularly applied to certain mineral ſprings, whoſe waters are impregnated with particles of iron, generally called chalybeates.

The word is Latin, *ferrugineus*, and derived from *ferrum*, iron.

FERRUGO, Rust. See the article Rust.

FERRUM, Iron. See Iron.

FERTILITY, that quality which denotes a thing fruitful or prolific.

FERULÆ, in ſurgery, ſplinters or chips of different matter, as of wood, bark, leather, paper, &c. applied to bones that have been disjointed, when they are ſet again.

FESSE, in heraldry, one of the nine honourable ordinaries, conſiſting of a line drawn directly acroſs the ſhield, from ſide to ſide, and containing the third part of it, between the honour-point and the nombril.

It repreſents a broad girdle or belt of honour, which knights at arms were anciently girded with.

Fesse Point is the exact center of the eſcutcheon. See the article Point.

Fesse Ways, or *In* Fesse, denotes any thing borne after the manner of a feſſe; that is, in a rank acroſs the middle of the ſhield.

Party per Fesse implies a parting acroſs the middle of the ſhield, from ſide to ſide, through the feſſe-point.

FESTI Dies, in Roman antiquity, certain days in the year devoted to the honour of the gods.

FESTINO, in logic, the third mood of the ſecond figure of ſyllogiſm, the firſt propoſition of which is an univerſal negative, the ſecond a particular affirmative, and the third a particular negative, as in the following example:

Fes No bad man can be happy,
ti Some rich men are bad men:
no *Ergo*, Some rich men are not happy.

FESTIVAL, the ſame with feaſt. See the article Feast.

FESTOON, in architecture and ſculpture, &c. an ornament in form of a garland of flowers, fruits, and leaves, intermixed or twiſted together.

It is in the form of a ſtring or collar, ſomewhat biggeſt in the middle, where it falls down in an arch; being extended by the two ends, the extremities of which hang down perpendicularly.

Feſtoons are now chiefly uſed in friezes, and other vacant places, which want to be filled up and adorned; being done in imitation of the long cluſters of flowers, which the ancients placed on the doors of their temples and houſes on feſtival occaſions.

FETLOCK, in the menage, a tuft of hair growing behind the paſtern-joint of many horſes; for thoſe of a low ſize have ſcarce any ſuch tuft.

FEUD, *Feodum*, the ſame with fee. See the article Fee-Estate.

FEUDAL, or Feodal, denotes any thing belonging to a fee. See the article Fee.

FEUDATARY, or Feodatary, a tenant who formerly held his eſtate by feodal ſervice. See the article Vassal.

FEVER, Febris, in medicine, a diſeaſe, or rather claſs of diſeaſes, whoſe characteriſtic is a preternatural heat felt through the whole body, or at leaſt the principal parts of it.

All fevers, of what kind ſoever, are attended with a preternatural heat of the blood and humours, which impairs the bodily ſtrength and its vital functions: wherefore nature raiſes all her forces, and engages the diſeaſe as a mortal enemy; and, if ſhe gets the better, drives out the cauſe of the diſorder by ſuch outlets as ſhe is able. This action is by phyſicians called the criſis of the diſeaſe.

As there is no fever cured without ſome conſiderable evacuation, raiſed either by nature or by art, the phyſician ought carefully to obſerve which way nature ſeems to intend the expulſion of the morbid matter, and to aſſiſt her by all poſſible means. Now this expulſion is very frequently made through ſeveral outlets of the body at a time; and an evacuation by one outlet, more or leſs, checks that by another; thus a looſeneſs checks a ſweat, and *vice verſa*: wherefore it is the phyſicians buſineſs to diſcern what evacuation is moſt likely to be of ſervice, and ſo to promote this, as to give the leaſt interruption poſſible to any other; for any one evacuation is not equally ſuitable to all perſons, both on account of the difference of conſtitution and of diſeaſes; although evacuations through every emunctory are ſometimes neceſſary, as we find by experience in malignant fevers.

But of all ſolutions of the diſeaſe the moſt deſirable is by ſweat; next to that by ſtool and urine; the worſt is by a hæmorrhage, whether it proceeds from the noſe, or from any other part, becauſe it indicates, that the blood is ſo far vitiated, that no proper ſeparation of the humour can be made.

Laſtly, ſome fevers terminate in abſceſſes formed in the glands, which, if they happen in the decline of the diſeaſe, and ſuppurate kindly, are ſalutary: wherefore the ſuppuration is to be forwarded by cataplaſms or plaſters, and ſometimes by cupping on the tumour; and then, if the abſceſs does not break ſpontaneouſly, it ought to be opened with the knife or a cauſtic.

At this time this rule of practice is generally right, not to exhauſt the patient's ſtrength by evacuations of any kind: and yet in ſome caſes there is a neceſſity for drawing a little blood; as when the humours are in great commotion, and the heat exceſſive; for this remedy, prudently adminiſtered, makes the tumour ripen kindly, becauſe nature has always a great abhorrence of a turbulent ſtate.

Continual Fevers.—There is no diſeaſe to which the uſeful precept, *principiis obſta*, is more applicable than to fevers; becauſe in the beginning it is generally eaſy to do good; but when the diſtemper has gained ground, the cure is often attended with difficulty: for a medicine, which early adminiſtered might have prevented the impending danger, frequently fails when the bodily ſtrength is exhauſted by the violence of the diſeaſe. However, a patient who applies late for aſſiſtance, is not to be abandoned to his fate; ſince it is certain, that thoſe diſeaſes, which in old times were aſcribed to the divine wrath, are frequently cured by natural means, even when they appear moſt deſperate: wherefore the phyſician ought to lay it down as an abſolute rule, never to be wanting in his duty.

And firſt, as blood-letting is a moſt excellent remedy in the beginning of all fevers; if it has happened to be neglected for ſome days, let us conſider whether it is ſtill proper to be ordered.

In caſe of intolerable pain in any part of the body, of difficulty of breathing, or a delirium, blood is to be taken away, according to the patient's ſtrength; with the lancet, if he be able to bear it; if too weak, by cupping; but if exceſſively ſo, by leeches: and if this may be done when the diſeaſe has got to the height, it ought for ſtronger reaſons to take place in the beginning: and let me obſerve by the way, that leeches are often of vaſt ſervice in a delirium. I have alſo ſometimes found, by experience, that pieces of lamb's lungs, applied warm to the head, have carried off the phrenzy, by the exudation of the noxious or ſuperfluous humour.

Fevers *attended with Eruptions*, the chief of which, after the ſmall-pox, meaſles, and plague, is the miliary fever, than which no fever puts on more various appearances. Puſtules, rough to the touch, break out ſooner or later all over the body; ſometimes red, ſometimes whitiſh, and again both ſorts intermixed; at one time ſmaller, at another larger and more elevated, and of a bad ſmell. Sobbing and anxiety about the heart are very frequent ſymptoms, which are often followed by a delirium and convulſions. The diſeaſe runs into a conſiderable length; and if it happen to end too ſoon, without a ſufficiently perfect criſis, it often brings on a bad habit of body. The red pimples are not ſo dangerous as the whitiſh; and the more lively their colour, the ſafer they are. Hence it appears, that this fever is more owing to a defect in the humours, and the animal ſpirits in particular,

cular, than to any bad quality of the air; and that it requires different methods of cure, according to its different circumſtances.

But of what kind ſoever the puſtules are, blood is to be drawn in the beginning, if the patient hath ſtrength to bear it; unleſs he be actually in a ſweat, in which caſe blood-letting is either to be omitted, or at leaſt to be put off for a day or two, or to ſome other convenient time.

Now red puſtules bear bleeding much better than the whitiſh: and though in both ſorts bliſters are ſerviceable, yet they are more neceſſary in the latter; and they are to be applied to the neck, head, and all the limbs, at proper diſtances of time. After all, I would adviſe the phyſician always to bear in mind, that the more ſparingly blood has been drawn, the more happily the diſeaſe generally terminates: for when the ſtrength has been exhauſted by evacuations towards the latter end, the eruption ſinks in, and the patient dies.

Nature's endeavours to expel the morbific matter through the ſkin, are to be aſſiſted by moderately cordial medicines. Of this tribe the moſt proper are the bezoardic powder, the compound powder of contrayerva, and the cordial confection; adding nitre in caſe of an inflammation: and this ſalt may be very advantageouſly joined to cordial medicines in almoſt all malignant fevers, at leaſt in the beginning. Toward the decline, warm bathing is ſometimes ſerviceable, in order to bring forth the remains of the puſtules.

But if, either at the height, or on the decline of the fever, the only appearance of an eruption is a vaſt number of pellucid veſicles, ſo ſmall as hardly to be ſeen: it is not ſafe to perſiſt too long in the uſe of internal medicines of this tribe, unleſs the length of the diſtemper has ſo far weakened the patient, as to render even more powerful cordials neceſſary: for ſuch little roughneſſes of the ſkin are not able to bring on a good criſis, but on the contrary, generally denote a difficult and tedious illneſs; wherefore, without diſcontinuing the bliſters, the cauſe of the diſeaſe is to be carried off by other ways, eſpecially through the inteſtinal canal by gentle purges of rhubarb, or manna and Glauber's ſalts.

It is to be obſerved, that this diſeaſe is not always terminated by any one ſort of criſis. It has ſometimes one ſort, ſometimes another; and, in ſome caſes, ſeveral ſorts together, as frequently happens in other malignant fevers. Thus, at the ſame time that there are other diſcharges of the morbific matter, a thruſh ſometimes breaks out, and ſpreads all over the mouth and throat. This commonly begins with a hiccup: and if it be whitiſh and very moiſt, and occaſion a plentiful ſpitting, it is ſo far from portending any great danger, that it is a ſign of the diſtemper's ending happily; but if it be of the black kind and dry, and the ſpittle rough and little in quantity, it is a fatal omen, as it indicates the mouth and throat choaked up with ſlimy phlegm. In theſe caſes it is proper to uſe gargles made of barley-water and ſyrup of mulberries, or ſome ſuch other ſyrup, or the pectoral decoction: for repellents of all kinds are to be carefully avoided.

It may poſſibly ſeem ſtrange to ſome, that Sydenham preſcribed the bark in this fever, and the aphthæ attending it, who ſays, he always found it to anſwer his expectations. But this was not a raſh practice in that ſagacious phyſician; for this fever often intermits when the aphthæ do not appear; but it more frequently ends upon their going off. In both caſes this excellent antidote is of very great ſervice. Sydenham was the firſt, among us, who deſcribed this fever, which, he ſays, took its riſe here in the month of February 1684, after the long ſevere froſt of the preceding winter. Hence it is probable, that it aroſe from the acrimony of the humours, induced by the conſtruction of the fibres of the ſkin from cold, and the conſequent diminution of perſpiration.

The Petechial Fever.—The petechiæ, from which this fever has its name, are broad red ſpots, like the bites of fleas, not riſing above the ſurface of the ſkin. When they are livid or black, they are of very dangerous prognoſtic; becauſe they are really ſo many little gangrenes; and therefore, the more numerous they are, the more their conſequence is to be dreaded.

The common practice of giving hot medicines in the beginning of this diſtemper, in order to raiſe ſweats, is quite wrong. It is much the ſafer way to check the gangrenous diſpoſitions of the humours by the bezoardic powder, or rather the compound powder of contrayerva, with nitre, as is before-mentioned; or to aſſiſt nature with the cordial confection diſſolved in ſimple, alexeterial water; and alſo to acidulate the patient's drink with dulcified ſpirit of nitre; to repair his ſtrength with Rheniſh wine; and, in fine, a very proper drink will be barley-water with juice of lemons: and all theſe liquors are to be drank plentifully. It will likewiſe be of uſe ſometimes to adminiſter ſome doſes of the calx of antimony and bezoardic powder mixed, in order to provoke ſweat; but the calx ſhould not be too much waſhed: yet it is neceſſary to admoniſh, that it is not an uncommon caſe, eſpecially towards the latter end of the diſeaſe, that the patient's weak low ſtate requires warmer cordials; ſuch as Virginia ſnake-root, contrayerva-root, the root of wild valerian, ſaffron, and the like: and infuſions of theſe in water will be far more convenient than any other powders, eſpecially if they be mixed with a ſmall quantity of diſtilled vinegar.

Intermitting Fever.—That this is not carried off by the Peruvian bark with a proper degree of certainty, without premiſing a vomit or a purge, or both, is not unknown to phyſicians; but to join ſome mild cathartic to this remedy will perhaps appear new in practice: for it is commonly thought among us, that this medicine has little or no effect, unleſs the patient be coſtive while he takes it: but long experience has taught me, that it is quite neceſſary to add a ſmall quantity of rhubarb to this febrifuge, ſo as to procure two ſtools at leaſt every day: nor have I ever obſerved that this procedure has leſſened its virtue, but rather rendered it more efficacious; for altho' ſtrong irritating cathartics raiſe ſuch diſturbances in the blood and humours, as make the proper medicines ineffectual; yet moderate purging is attended with this good effect, that the ſtomach better digeſts whatever is taken in, whether medicines or food; whereby their fineſt and moſt wholeſome parts paſs into the maſs of blood.

The occaſion of my contriving this method of giving the bark was this: about five and thirty years ago intermittent fevers, of a worſe ſort than ordinary, were very rife, and frequently terminated in a bad habit of body, and even in a dropſy; which conſequences, when I had maturely conſidered, I thought that this method might probably guard againſt them; nor was I deceived in my opinion: and the ſucceſs, with which it was attended, encouraged me to purſue it, whenever this diſeaſe attacked bodies loaded with groſs humours: but I was well aware of the danger of purging too much; for after having given a drachm or two of rhubarb in this manner, it was my uſual cuſtom to omit the purgative, and continue the uſe of the febrifuge alone: and beſides the advantages already recited, I made this obſervation, that when the diſeaſe is carried off by this method, there is always leſs danger of a relapſe.

Now, with regard to this noble medicine, I have this one admonition to give, that it is not proper in any other fevers but thoſe of the intermittent kind: for in continuals it is ſo far from being of ſervice, that it does much miſchief; and it is alſo pernicious in thoſe hectics which are accompanied with ulcers of any kind of the internal parts; though they often have periodical returns, and much reſemble quotidian or tertian intermittents: whence it may not perhaps appear an improbable conjecture, that this medicine operates on the bile alone; for that the bile has a conſiderable ſhare in cauſing intermitting fevers, I have not the leaſt doubt.

However, it ſometimes happens that this febrifuge fails in true intermittents; which failure is generally owing to a bad habit of body: wherefore the phyſician ſhould uſe his beſt endeavours to diſcover in what part the fault lies; and it will be commonly found to be in the viſcera and glands of the abdomen: upon this account it will be neceſſary to preſcribe ſome purges, and ſometimes vomits; and in the intermediate days deobſtruents and ſtomachics, the beſt of which are aromatic bitters and preparations of ſteel: and for the ſame reaſon it is, that quartans are of more difficult cure than any other intermittents; for in

theſe the blood and humours are inert and exceſſively viſcid; ſo that there are two diſeaſes to be conquered together, the bad habit of body and the fever; which is generally done effectually, by joining Virginia ſnake-root and ſteel with the bark: however, it may not be improper to take notice, that in ſome caſes where the bark did not anſwer, I have taken off intermitting fevers with a powder compoſed of chamomile flowers, myrrh, ſalt of wormwood, and a little alum.

But there is more danger attending that ſort of intermitting fevers, by the Greeks named ἡμιτριταῖος, that is, ſemitertian. This fever returns every third day; and of forty-eight hours the fit commonly takes up about thirty-ſix, more or leſs; nor does the fever go off entirely, but only remits between the paroxyſms. Hence Galen was right in ſaying, that it was compounded of a continual, quotidian, and an intermitting tertian.

Thus a particular regard is due to this diſeaſe, which ſeems to be cauſed by an inflammation of ſome internal parts, accompanied with obſtructions from bilious humours and too viſcid lymph: wherefore blood is to be drawn once or oftener, according to the patient's ſtrength; and gentle purgatives, ſuch as the diuretic ſalt, manna with Glauber's ſalt, and the like, are to be ordered and repeated at proper diſtances of time; nor ought we to be haſty in giving the bark, for fear it ſhould increaſe the inflammation by adding to the obſtruction of the viſcera, and bring on a hectic. It will be much ſafer, firſt, to order the ſaline draughts, with juice of lemons, ſalt of wormwood, and ſimple cinnamon water, to be taken frequently.

Epidemic FEVERS.—Theſe are cauſed by ſome fault in our ambient air; and that is chiefly owing to the exceſs of heat, cold, drought, or moiſture, or to the unſeaſonable viciſſitudes of theſe qualities.

In Greece and Aſia, where the ſeaſons are generally uniform, and the winds pretty regular from certain but different quarters in the different months of the year, it was eaſy for men of ſagacity to obſerve the changes of the weather, with their good and bad effects: and on a long uſe of this method of obſervation was built the art of prognoſtic in diſeaſes, wherein Hippocrates, the father of phyſic, firſt excelled.

But in our climates, ſuch is the inconſtancy of the weather, and ſo many are the cauſes that raiſe different and even contrary winds on a ſudden, that it ſeems impoſſible to erect any ſolid ſuperſtructure on that foundation: and accordingly Sydenham, who, in imitation of Hippocrates, attempted to deſcribe the fevers of each reſpective year, and to account for their differences from the differences of the weather and ſeaſons, found at length "That he had made no progreſs in diſcovering the cauſes of epidemical diſeaſes by obſerving the manifeſt qualities of the air; as having remarked that in different years, which agreed perfectly well in the viſible temperature of the air, the reigning diſeaſes were very different, and ſo on the contrary; and likewiſe, that there are various conſtitutions of years, which depend not on heat, cold, drought, or moiſture, but on ſome occult and inexplicable alteration in the very bowels of the earth."

Now this matter, in my opinion at leaſt, ſtands thus: that the manifeſt qualities of the air have a conſiderable ſhare in producing epidemic diſeaſes, is a point that admits of no doubt; but there are other conjunct cauſes which alter the force of thoſe qualities, either by increaſing or diminiſhing them. Theſe chiefly ſpring from the earth, as Lucretius wiſely ſaid:

——*ubi puterem humida noctu eſt,*
Intempeſtivis pluviiſque et ſolibus icta.

When ſhe's grown putrid by the rains, and ſweats
Such noxious vapours, preſſed by ſcorching heats.

Now as this terreſtrial putridity is chiefly occaſioned by rotted vegetables, and ſometimes alſo by the dead bodies of animals, and by minerals; ſo the waters, eſpecially of lakes and moraſſes, which have their plants and animals, in the ſame manner frequently exhale peſtilential vapours, which infect the circumambient air. In this claſs may be ranged, though rarely happening in our climates, inundations, earthquakes, eruptions from mountains, and all other remarkable and uncommon phenomena of nature, which are capable of filling the air we breathe, with particles offenſive to animal life: for theſe affect our bodies, and prepare them for the eaſy reception of diſeaſes.

Slow or hectic FEVERS.—Theſe are owing to ſo many different cauſes, that they may well ſeem not to be the ſame, but different diſeaſes. Of all this tribe the moſt pernicious are thoſe which ariſe from an ulcer in any principal part of the body, the lungs eſpecially, by the purulent matter mixing with the blood, and diſturbing its natural motion.

Now it is to be obſerved, that the perſons moſt liable to theſe exulcerations of the lungs, are ſuch as have been afflicted with ſcrophulous diſorders in their infancy or youth. To which purpoſe the experienced Dr. Radcliffe was wont to ſay, that pulmonary conſumptions in this and the colder countries are generally ſcrophulous: and, indeed, in the diſſection of bodies dead of conſumptions, we very often find the lungs beſet with tubercles or indurated glands, which had ſuppurated and thrown off purulent matter.

Medical writers have accurately deſcribed the various ſtages of this diſeaſe, as they ſucceed each other; but they have not taken ſufficient notice, that ſome of its firſt cauſes have their periods or returns: and yet it is of great conſequence to obſerve and prevent theſe periodical returns, as much as poſſible. Thus we ſee ſeveral perſons at certain or ſtated times ſeized with a ſpitting of blood, or a defluxion of thin ſeroſities on the lungs, and ſometimes with bilious vomitings. In all theſe caſes the bark is of ſervice, if joined with pectorals, and given before the expected return of the diſorder; which rule holds equally good in other hæmorrhages: but when the lungs are actually ulcerated, this ſame medicine is very prejudicial.

In ulcers of the lungs phyſicians particularly recommend a milk courſe, as having the double advantage of being food and phyſic: but this practice is liable to ſome caution, becauſe ſome people have a natural averſion to milk. Moreover, in head-achs, acute fevers, and exceſſive thirſt occaſioned by them, and likewiſe in flatulencies, in bilious looſeneſſes, and very bloody ſtools, milk ought always to be deemed a poiſon. Now we generally give the preference to aſſes milk, though leſs nutritive; becauſe it is more cooling and detergent: but when it cannot be conveniently had, whey made of cows milk, or even of goats milk, may be ſubſtituted in its room, eſpecially if the goats have been fed on fragrant herbs: but cows milk itſelf, although diluted as uſual with barley-water, is very frequently inconvenient: and the whey may be rendered more ſuitable to the diſeaſe by infuſing ſtomachic and carminative herbs in it: but it happens unluckily ſometimes, that when milk is extremely neceſſary for the body, ſuch is the laxity of the inteſtines that they cannot bear it. In this caſe the milk may be medicated in this manner: take of red roſes dried, of balauſtines, pomegranate rind and cinnamon, each one drachm; boil them in a pint of cow's milk; when the decoction begins to boil, pour a little cold water in it, to make it ſubſide; repeat this proceſs ſeveral times, till you have uſed a pint of water, and till the milk and water together are reduced to a pint: then ſtrain off the liquor, ſweeten it with ſugar, and divide it into convenient draughts, ſo that the patient may take the whole quantity every day. This diet will anſwer the double intention of affording nouriſhment and reſtraining the looſeneſs, without putting the leaſt obſtacle to the uſe of their food or medicines.

Now it is of the utmoſt conſequence to attempt the cure of this dreadful diſeaſe early; and as it ariſes from inflammation, it requires not only one, but ſeveral bleedings. If the blood be thick and black, or fizy, it is called bad blood, and is thought to indicate farther bleeding; but if it be red and florid, it is eſteemed good, and the lancet is no more uſed: but this notion is apt to lead into miſtakes; for it is not uncommon to ſee blood drawn, when in the higheſt effervescence, extremely florid, and at the ſame time thick and ſtiff: in which caſe bleeding ought to be repeated till its redneſs and fizineſs are diminiſhed; which may be done without danger. It will poſſibly be thought a raſh practice to draw blood, even when the patient is much waſted in his fleſh and very weak:

weak: but it is better to try a doubtful remedy than none; and a temporary leſſening of the ſtrength is of ſervice, when attended with a removal of part of the cauſe, which would weaken the body more and more every day: wherefore, if the lungs be ulcerated, and the fever run high, it will be proper to take away as much blood as the patient can bear, at proper intervals, ſo as to allow the body time to recruit. I have ſeen caſes judged almoſt deſperate, when this method of practice ſucceeded well; but if it happen otherwiſe, the phyſician is not to be branded with the death of the patient, whoſe viſcera were ſo corrupted that it was impoſſible to ſave him.

Fumigations with balſamics, ſuch as frankincenſe, ſtorax, amber, or benzoin, in order to correct and ſweeten the acrid and ſalt humours, are of vaſt ſervice in ſome caſes; which is to be done by throwing the ingredients on red-hot coals, and receiving the fumes through a proper tube directly into the wind-pipe and lungs. This method of adminiſtering balſamics is almoſt entirely neglected, as uſeleſs: but whoſoever conſiders the length of the way, which they muſt make by the blood veſſels, before they reach the lungs; and what a ſmall part of them comes to the place of their deſtination, will eaſily ſee, that this is the beſt way of communicating their virtue, if they have any.

For the ſame reaſon I have known the ſmoke of the balſam of Tolu, ſucked into the lungs through a proper tube, as we ſmoke tobacco, to be of ſignal benefit, eſpecially in ſpitting of blood.

To theſe little ſuppurations it may not be improper to ſubjoin a larger abſceſs, which is ſometimes formed in the ſame part, and is named vomica. — This diſeaſe, tho' bad in itſelf, and though it often terminates in a conſumption, yet it is not attended with ſo much danger as thoſe leſſer exulcerations: for I have ſeen caſes, wherein the patients in a fit of coughing threw up a pint or two of purulent matter, mixed with blood, of ſuch an exceſſive ſtench, that people could not bear the room; and yet they were perfectly cured by a milk diet and balſamics, with anodynes at proper intervals.

There are two other ſpecies of conſumption, which waſte a perſon different ways. In one the body is not nouriſhed; and as ſome particles are always naturally flying off, and nothing coming to ſupply their place, an exceſſive waſting of fleſh enſues, which is called an atrophy. This is very frequently owing to a defect in the nervous fluid; and is either accompanied with a cachexy, which is the other ſpecies, or gradually brings it on. In both ſpecies the food is corrupted by reaſon of the bad habit of body, and the parts are not recruited; and therefore a well regulated courſe of living, and ſteel medicines ſtrengthen the ſtomach, with laxatives at proper intervals, are particularly indicated.

Laſtly, in all decays, exerciſe and frictions according to the patient's ſtrength, ought to be conſtantly uſed: change of air is generally of ſervice, and ſometimes a long ſea-voyage. Patients labouring under diſorders of the lungs, in this country, are very juſtly ſent to Liſbon or Naples: but riding on horſeback, if practicable, if not, in a coach, or a litter at leaſt, or ſome other way of moving the body, is always proper. *Mead's Monita et Præcepta.*

Bilious or Choleric FEVER, a ſpecies of acute fever, owing its origin to diſtemperatures of the bile.

The general ſigns of the bilious or choleric fever, are a remarkable anxiety, and frequent complaints about the breaſt, as of a ſtraitneſs and painful heat. A violent heat in the inſide of the mouth, and inſatiable and intolerable thirſt, trembling and convulſive motions of the joints, and violent deliriums. Dryneſs of the mouth and tongue are often ſo terrible in this diſeaſe, that the ſkin cracks with it; and often the whites of the eyes, ſometimes the whole body, becomes yellowiſh. The peculiar and appropriated ſymptoms of a cholerica febris, ſtrictly ſo called, are an univerſal langour and debility of the limbs.

A ſevere ſhivering firſt ſeizes the patient, and is ſoon ſucceeded by a very violent heat, and raging pain in the head; and, after the two firſt days, there uſually are very terrible ſtrainings and reachings to vomit. The matter brought up at theſe times is cauſtic, acrid, and bilious, and inflames and even ulcerates the fauces; and, if voided upon a ſtone floor, effervesces violently. If this vomiting abates, there immediately comes on a diarrhœa attended with a teneſmus, occaſioned by the irritation of this ſharp matter in the rectum. Faintings alſo are very frequent in this diſeaſe, eſpecially where the vomitings do not bring up a ſufficient quantity of the offending matter. The peculiar and appropriated ſigns of the cauſus, ſtrictly ſo called, are theſe: a violent and inſatiable thirſt, greater than that in any other fever. The bowels are always bound, and it is but very ſeldom that there is any tendency to vomit. The urine is reddiſh and turbid, and, after ſtanding ſome time, depoſits a red ſediment. Often there is a ſenſible pain and ſoreneſs in the præcordia, ſo that the patient cannot bear the leaſt touch upon the breaſt; and uſually, in the courſe of the diſeaſe, there are faintings and violent convulſions.

Perſons moſt ſubject to this diſeaſe are ſuch as eat largely, and drink heavy and imperfectly fermented liquors after it. The cholerica febris, properly ſo called, is moſt frequent with thoſe of a cholerico-ſanguineous habit, and ſuch as feed on high-ſeaſoned meats, and drink abundance of wine or other ſtrong liquors; and is often brought on ſuch perſons by their falling into violent paſſions after a full meal. The cauſus peculiarly attacks the people of melancholic habits, who are much inclined to paſſion, but ſuppreſs it, and who are naturally coſtive.

Method of cure. — The cure of theſe diſeaſes conſiſts in the mitigating the violent ſharpneſs of the humour, and promoting its evacuation; and, finally, in abating the burning heat brought on by it. The utmoſt endeavours are firſt to be made to correct and alter the morbific matter. To this purpoſe the ſeveral preparations of nitre, with the teſtaceous powders and mucilaginous ptiſans, with ſmall mixtures of lemon-juice, and frequent draughts of cooling and diluting liquors, are to be given moderately warm. If the coſtiveneſs be too violent, clyſters of broth muſt be injected, with the addition of a little oil and ſalt; and, if neceſſary, ſmall doſes of rhubarb. To quell the febrile heat and emotion of the blood, the miſtura ſimplex may be given with great ſucceſs; and there is often a ſenſible good effect from the application of rags, wetted in camphorated ſpirit of wine, to the pit of the ſtomach. After the morbific matter is evacuated, the reachings to vomit may be allayed by gentle opiates. All hot medicines change the bilious fevers into inflammatory ones, and the common ſudorifics drive the morbific matter into the blood, and uſually bring on almoſt immediate diſcolourings of the ſkin, like thoſe of the jaundice. Bleeding, though performed ever ſo early in the diſeaſe, ſeldom does any good, except only in remarkable plethoric habits. *Junker's Conſp. Med.*

Colliquative FEVER is that in which the body is much emaciated and conſumed in a ſhort ſpace of time: the ſolid parts, and the fat itſelf waſte, ſometimes by a diarrhœa, ſometimes by ſweat, by urine, or by feveriſh heats alone, without any ſenſible diſcharge. A colliquative fever is obſerved to accompany a cancer of the breaſt, with a diarrhœa. See the articles DIARRHOEA, DIABETES, CANCER, &c.

For this diſeaſe, emulſions of almonds, and of the four cold ſeeds, as alſo aſſes, goats, or woman's milk are proper; or cow's milk with the juice of water-creſſes; chicken broth, broth made of river crabs, or wood ſnails bruiſed.

Diary FEVER, the ſame with ephemera. See EPHEMERA.

Hoſpital FEVER. See HOSPITAL.

Yellow FEVER. See the article *Bilious* FEVER.

FEVERFEW, in botany, a plant with firm branched ſtalks, and rough leaves, each of which is compoſed of two or three pairs of indented oval ſegments, ſet on a middle rib, with an odd one at the end, cut into three lobes: the flowers ſtand on the tops in the form of an umbel, conſiſting each of a number of ſhort white petals, ſet round a yellow diſk, which is followed by ſmall ſtriated

ſeeds. It is biennial, or of longer duration; grows wild in hedges and uncultivated places, and flowers in June.

The leaves and flowers of feverfew have a ſtrong, not agreeable ſmell, and a moderately bitter taſte; both which they communicate, by warm infuſion, to water and to rectified ſpirit.

This herb is recommended as a warm, aperient, carminative bitter; ſuppoſed to be particularly ſerviceable in female diſorders, and to be a medicine of no inconſiderable virtue, in ſome degree ſimilar to chamomile.

FEUILLANS, an order of barefooted monks, who obſerve the ſame rules with the bernardines. See BERNARDINES.

FIAT, in law, a ſhort order or warrant ſigned by a judge, for making out and allowing certain proceſſes.

FIAT JUSTITIA, is where the king, on a petition to him for his warrant to bring a writ of error in parliament, writes on the top of it *fiat juſtitia*, "let juſtice be done;" upon which the writ of error is made out.

FIBER, the beaver, in zoology, is made, by Linnæus, a ſpecies of caſtor. See the article BEAVER.

FIBRE, in anatomy, a perfectly ſimple body, or at leaſt as ſimple as any thing in the human ſtructure; being fine and ſlender like a thread, and ſerving to form other parts: hence ſome fibres are hard, as the bony ones; and others ſoft, as thoſe deſtined for the formation of all the other parts.

The fibres are divided alſo, according to their ſituation, into ſuch as are ſtraight, oblique, tranſverſe, annular, and ſpiral; being found arranged in all theſe directions, in different parts of the body; for an account of which ſee BONE, MUSCLE, NERVE, ARTERY, VEIN, &c.

FIBRE is alſo uſed to denote the ſlender filaments which compoſe other bodies, whether animal, vegetable, or mineral; but more eſpecially the capillary roots of plants. See PLANT, WOOD, &c.

FIBRILLA, a term ſometimes uſed for a very minute or ſlender fibre.

FIBROSE, ſomething conſiſting of fibres, as the roots of plants. See ROOT.

FIBULA, in anatomy, the outer and ſmaller bone of the leg, called alſo perone. It is nearly of a triangular figure, and ſtands parallel to, but diſtant from, the tibia, or inner bone of the leg. Its upper extremity does not reach to the os femoris, but is only joined to the external ſide of the tibia; and its lower extremity, called malleolus externus, concurs in the articulation of the tarſus, which its eminence ſerves to ſtrengthen, by rendering a luxation leſs eaſy. It has no particular motion of its own, but wholly follows that of the tibia.

FIBULÆUS, a muſcle of the leg, more uſually called peronæus. See PERONÆUS.

FICUS, in botany. See FIG.

FIDD, among ſailors, a piece of wood or iron thruſt through a hole in the foot of the top-maſt, after it is drawn up to its utmoſt height. See MAST and TRUSSEL TREES.

In the article CAP we obſerved, that it was uſed to keep ſteady the top maſt above the frame of the top, as it is kept ſteady below by the truſſel-trees: the fidd reſts upon the truſſel-trees, and with it of courſe the whole weight of the top-maſt: the fidd-hole is therefore juſt above them when the top-maſts are erect.

FIDE JUSSOR, among civilians, the ſame with a ſurety. See SURETY.

FIELD, *Campus*, in agriculture, a piece of ground incloſed, whether for tillage or paſture. See TILLAGE and PASTURE.

FIELD, in heraldry, is the whole ſurface of the ſhield, or the continent, ſo called becauſe it containeth thoſe atchievements anciently acquired in the field of battle. It is the ground on which the colours, bearings, metals, furs, charges, &c. are repreſented. Among the modern heralds, field is leſs frequently uſed in blazoning than ſhield or eſcutcheon. See SHIELD, &c.

FIELD BOOK, in ſurveying, that wherein the angles, ſtations, diſtances, &c. are ſet down. See SURVEYING.

FIELD-COLOURS, in war, are ſmall flags of about a foot and a half ſquare, which are carried along with the quarter-maſter general, for marking out the ground for the ſquadrons and battalions.

FIELD-FARE, in ornithology, the Engliſh name of the variegated turdus, with a hoary-head. See the article TURDUS.

It is larger than the common black-bird, and with us is a bird of paſſage, coming over in great numbers in winter.

FIELD-FORT, in fortification. See FORT.

FIELD-OFFICERS, in the art of war. See the article OFFICER.

FIELD-PIECES, ſmall cannons, from three to twelve pounders, carried along with an army in the field. See CANNON.

FIELD-STAFF, a weapon carried by the gunners, about the length of a halbert, with a ſpear at the end; having on each ſide, ears ſcrewed on, like the cock of a match-lock, where the gunners ſcrew in lighted matches, when they are upon command; and then the field-ſtaffs are ſaid to be armed.

FIELD-WORKS, in fortification, are thoſe thrown up by an army in beſieging a fortreſs, or by the beſieged to defend the place. Such are the fortifications of camps, highways, &c.

Elyſian FIELDS. See ELYSIAN.

FIERI FACIAS, in law, a writ that lies where a perſon has recovered judgment for debt or damages in the king's courts againſt one, by which the ſheriff is commanded to levy the debt and damages on the defendant's goods and chattels.

FIFE, in muſic, is a ſort of wind-inſtrument, being a ſmall pipe. See PIPE.

FIFTH, in muſic, the ſame with diapente. See the article DIAPENTE.

FIG-TREE, *Ficus*, in botany, a genus of plants producing male and female flowers ſeparate, neither of which have any flower leaves: the ſtamina are three ſetaceous filaments of the length of the cup; and the fruit is large, fleſhy, and of a terbinated figure; being properly nothing more than the common calyx, or cup, of the fructification.

Method of cultivating FIG-TREES.—Theſe trees are always planted as ſtandards, in all warm countries; but in England they are generally planted againſt walls, there being but few ſtandard fig-trees, at preſent, in the Engliſh gardens: however, ſince the fruit is found to ripen well upon the ſtandards, and the crop of figs is often greater upon them, than upon thoſe trees againſt walls, it may in time become the general practice to plant them either in ſtandards or eſpaliers: the latter, I think, will ſucceed beſt in England, if they were managed as in Germany; where they untie the fig-trees from the eſpalier, and lay them down, covering them from the froſt with ſtraw or litter, which prevents their ſhoots being injured by the froſt; and this covering is taken away gradually in the ſpring, and not wholly removed until all the danger of froſt is over; by which management they generally have a very great crop of figs; whereas, in England, where the trees grow againſt warm walls, if the ſpring proves warm, the young figs are puſhed out early; and the cold, which frequently returns in April and May, cauſes the greateſt part of the fruit to drop off, ſo that our crop of figs is generally more uncertain than moſt other ſort of fruit; and it frequently happens, that trees which are planted againſt north and eaſt aſpected walls, produce a greater quantity of fruit in England, than thoſe which are planted againſt ſouth and ſouth-eaſt aſpects, which muſt happen from the latter putting out their fruit ſo much earlier in the ſpring than the former: and, if there happen cold froſty nights, after the figs are come out, which is frequently the caſe in this country, the forwardeſt of the figs are generally ſo injured as to drop off from the tree ſoon after. In Italy, and the other warm countries, this firſt crop of figs is little regarded, being few in number; for it is the ſecond crop of figs which are produced from the ſhoots of the ſame year, which is their principal crop; but theſe rarely ripen in England; nor are there above three or four ſorts which ever ripen their ſecond crop, le

the ſummer prove ever ſo good; therefore it is the firſt crop which we muſt attend to in England: ſo that when theſe trees are growing againſt the beſt aſpected walls, it will be a good method to looſen them from the wall in the autumn; and, after having diveſted the branches of all the latter fruit, to lay the branches down from the wall, faſtening them together in ſmall bundles, ſo that they may be tied to ſtakes, to keep them from lying upon the ground; the damp whereof, when covered in froſty weather, might cauſe them to grow mouldy; and hereby they will be ſecured from being broken by the wind. When they are thus managed in the autumn, if the winter ſhould prove very ſevere, the branches may be eaſily covered with peas-haulm, ſtraw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of froſt: and when the weather is mild the covering muſt be removed, otherwiſe the figs will come out too early; for the intention of this management is to keep them as backward as poſſible: then in the ſpring, when the figs are beginning to puſh out, the trees may be faſtened up to the wall again. By this management I have ſeen very good crops of figs produced in two or three places.

I have alſo ſeen great crops of figs in ſome particular gardens, after very ſharp winters, when they have, in general, failed in other places, by covering up the trees with reeds made into panels, and fixed up againſt the walls.

In the pruning of fig-trees, the branches muſt never be ſhortened; becauſe the fruit are all produced at the upper part of the ſhoots; ſo, if theſe are cut off, there can be no fruit expected; beſides, the branches are very apt to die after the knife; ſo that, when the branches are too cloſe together, the beſt way is to cut off all the naked branches quite to the bottom, leaving thoſe which are beſt furniſhed with lateral branches at a proper diſtance from each other, which ſhould not be nearer than a foot; and, when they are well furniſhed with lateral branches, if they are laid four or five inches farther aſunder, it will be better.

The beſt ſeaſon for pruning of fig-trees is in autumn, becauſe, at that time, the branches are not ſo full of ſap; ſo they will not bleed ſo much as when they are pruned in the ſpring; and, at this ſeaſon, the branches ſhould be diveſted of all the autumnal figs; and the ſooner this is done, when the leaves begin to fall off, the better will the young ſhoots reſiſt the cold of the winter. There are ſome ſeaſons ſo cold and moiſt that the young ſhoots of the fig-trees will not harden, but are ſoft and full of juice: when this happens, there is little hope of a crop of figs the ſucceeding year; for the firſt froſt in the autumn will kill the upper part of theſe ſhoots, for a conſiderable length downwards: whenever this happens, it is the beſt way to cut off all the decayed part of the ſhoots, which will prevent the infection from deſtroying all the lower part of the branches; and by this method I have ſeen a moderate crop of figs put out from the lower part of the ſhoots, where, if the ſhoots had not been injured, there would have been no fruit produced; becauſe it is chiefly from the four or five uppermoſt joints of the ſhoots that the fruit comes out: and it is for this reaſon, that as many of the ſhort lateral branches ſhould be preſerved as poſſible, thoſe being the moſt productive of fruit; for, where the long ſtraight ſhoots are faſtened up, there will be no fruit, but at their extremities; ſo that all the lower part of the trees will be naked, if there be not a particular regard had to ſupply young ſhoots in every part of the trees. *Miller; Gard. Dict.*

Figs, both freſh and dry, are very wholeſome food; they are nutritive and emollient; they are alſo good in diſorders of the breaſt and lungs; but a too free uſe of them has ſometimes brought on obſtructions of the viſcera, a common complaint in the Levant. They are frequently made ingredients in our pectoral decoctions, and by ſome are greatly recommended againſt nephritic complaints. They are much uſed externally by way of cataplaſm, either roaſted or boiled in milk, for the ripening of tumors, and for eaſing the pain of the piles.

Fig, in farriery, a ſort of wart on the ſruſh, and ſometimes all over the body of a horſe. The figs that appear on the ſruſh or ſole make an evacuation of malignant ſtinking humours, that are very hard to cure.

FIGHT. See Battle.

FIGURAL, Figurate, or Figurative, a term applied to whatever is expreſſed by obſcure reſemblances. The word is chiefly applied to the types and myſteries of the Moſaic law; as alſo to any expreſſion which is not taken in its primary and literal ſenſe.

Figural, or Figurative Numbers, are ſuch as do or may repreſent ſome geometrical figure in relation to which they are always conſidered, as triangular numbers, pentagonal numbers, pyramidal numbers, &c.

FIGURATIVE, among grammarians, is the ſame with what is otherwiſe called characteriſtic. See Characteristic.

Figurative Counterpoint, in muſic, is that wherein there is a mixture of diſcords along with the concords. See the article Counterpoint.

Figurative Descant, in muſic. See the article Descant.

FIGURE, in philoſophy, the ſurface or terminating extremities of any body.

Figures, in arithmetic, are certain characters whereby we denote any number, which may be expreſſed by any combination of the nine digits; as 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0.

Figure, in aſtrology, is applied to the deſcription, ſtate, and diſpoſition of the heavens at a certain hour, where the places of the planets and ſtars are marked in a figure of twelve triangles called houſes, with regard to the horoſcope to be drawn from it. They likewiſe call it horoſcope and celeſtial themis.

Figure, in conic ſections, according to Apollonius, is the rectangle of the latus rectum and tranſverſum in the hyperbola and ellipſis. De la Hire calls the rectangle of any diameter and its proper parameter, in the hyperbola and ellipſis, the figure of that diameter.

Figure, in dancing, denotes the ſeveral ſteps which the dancer makes in order and cadence, conſidered as they mark certain figures on the floor.

Figure, in fortification, the plan of any fortified place, or the interior polygon; of this there are two ſorts, regular and irregular; a regular figure is that where the ſides and angles are equal; an irregular is the contrary.

Figure, in geometry, the ſuperficies included between one or more lines, of which there are three ſorts, as rectilineal, curvilineal, and mixed figures: rectilineal have their extremities all right-lines, as triangles, quadrilaterals, &c. Curvilineal are ſuch as have their extremities crooked, as circles, ellipſes, &c. Mixed, are partly right-lines and partly crooked, as a ſemicircle, ſegment of a circle, &c.

FILAMENT, a ſmall fine fibre or thread, which compoſes the texture of the fleſh, nerves, ſkin, &c. of an animal: and it is likewiſe applied to the component parts of vegetables; as alſo to the fibres belonging to their roots. It is alſo uſed to ſignify that viſcid concreted matter, which appears like hairs or threads in urine.

The word is Latin, *filamentum*, which is a diminutive of *filum*, a thread.

Filaments, among botaniſts, is particularly uſed for the ſtamina. See the article Stamina.

FILAZER, or Filacer, an officer of the Common-Pleas, ſo called from his filing thoſe writs whereon he makes out proceſs.

FILBERT, or Filberd, the fruit of the corylus, or hazel. This ſpecies of nuts is more nouriſhing than the common ones; but is hard to digeſt. They are however worthy of being propagated in orchards and gardens; which is done by planting them in February.

FILE, among mechanics, a tool uſed by workmen in metal, &c. in order to ſmooth, poliſh, or cut. It is uſed, in pharmacy, to reduce hard ſubſtances to fine particles, whoſe conſiſtence will not admit of powdering.

File or Label, in heraldry, conſiſts ſometimes of more, and ſometimes of fewer points. According to Guillim, it is borne as a charge in a coat of arms: but it is uſually the difference or mark of diſtinction, which the

elder brother bears in his coat during his father's life-time. Some call the file the upper horizontal line, and the label the point that iſſues from it.

FILE, in the art of war, a row of ſoldiers, ſtanding one behind another, which is the depth of the battalion, or ſquadron. The files of a battalion of foot are generally three deep; as are ſometimes thoſe of a ſquadron of horſe. The files muſt be ſtraight, and parallel one to another.

FILIGRANE, or FILIGREE-WORK, any piece of gold or ſilver-work that is curiouſly done, with grains or drops on the filaments or threads.

FILING, in ſmithery, the operation of faſhioning metalline bodies by means of a file. See FILE.

FILIPENDULA, dropwort, in botany, a genus of plants, whoſe characters are the following.

The root is fibrous and perennial, with glandulous bulbs faſtened to it: the leaves are finely jagged, like thoſe of milleſoil: the calyx is monophyllous, denticulated, and divided into ſix or ſeven ſegments, which are retroflected, or bent backwards: the flowers are hexapetalous or heptapetalous, looſely diſpoſed in panicles on long ſtalks, which are almoſt naked: the ſtamina are numerous, and ſituated on the reflected margin of the calyx: the fruit is generally round, and contains many ſeeds compacted together, each of them furniſhed with its tube.

This plant contains a ſalt, approaching to that of alum; but it is mixed with a great deal of ſulphur. All authors agree that it is very diuretic and aperitive; and is alſo recommended for the epilepſy and dyſentery.

FILIX, in botany, an order of the cryptogamia claſs of plants, comprehending the fern, horſe-tail, adder's tongue, maiden-hair, ſpleenwort, polypody, &c. See the articles FERN, HORSE-TAIL, &c.

FILLER-HORSE, one yoked immediately to a cart. See the article CART.

FILLET, in heraldry, the fourth part of the ordinary called a chief, which is placed in the chief point of the eſcutcheon.

FILLET, in painting, gilding, &c. is a little rule or reglet of leaf-gold drawn over ſome mouldings; or on the edges of frames, &c. eſpecially when painted white, by way of ornament.

FILLET, in anatomy, the nervous ligament under the tongue, which midwives uſually divide with their nail, or a ſixpence, immediately after the child's birth: it is moſt commonly called the frænum.

FILLET, or FILET, in architecture, a little ſquare member, or moulding, uſed in divers places and on divers occaſions; but generally as a crowning over a greater moulding. It is called liſta or liſtella by the Italians; by the French, reglet; and by others band and bandelette.

FILLET, in the menage, the loins of an horſe, which begin at the place where the hinder part of the ſaddle reſts.

FILLING *the Sails*, in the ſea-language, the act of diſpoſing a ſail in ſuch a manner, that the wind preſſing into the cavity or belly of it ſhall force the ſhip forward, or a-head, in contradiſtinction to backing, which forces her a-ſtern; and ſhivering, which makes her remain almoſt in a ſtate of reſt, neither advancing nor retreating. It may appear ſomething remarkable, but is certainly true, that a ſhip may be forced backward or forward, or may remain in her place, with any wind, while her ſtem is all the while directed to one part of the horizon; and theſe different ſtates of motion or reſt may be communicated by backing, filling, or ſhivering the ſails, by drawing the braces on one ſide, and looſening them on the other. See the articles BRACE, BACKING, and SHIVERING.

FILLY, a term among horſe-dealers, to denote the female or mare colt. See the article FOAL.

FILM, in botany, that woody ſkin which ſeparates the ſeeds in the pods of plants.

FILTER, or FILTRE, in chemiſtry, a ſtrainer, commonly made of bibulous or filtring paper, in the form of a funnel, through which any fluid is paſſed, in order to ſeparate the groſs particles from it, and render it limpid. This filtre is put into a funnel, with the ſmall end in the veſſel for the reception of the filtrated liquor, and then the liquor is poured into the paper, not too much at once, for fear of burſting it. A filtre is alſo made of a woollen bag, called Hippocrates's ſleeve, or one of linen, according to the nature of the liquor to be filtred.

FILTRATION, in chemiſtry. See DEPURATION.

FIMBRIÆ, denotes appendages diſpoſed by way of fringe round the border of any thing: ſuch are thoſe about the thicker extremities of the Fallopian tubes. See GENERATION.

FIMBRIATED, in heraldry, an ordinary with a narrow border or hem of another tincture.

This, in Latin, is called *fimbriatus*; that is, edged or fringed.

FIN, *Pinna*, in natural hiſtory, a well known part of fiſhes, conſiſting of a membrane ſupported by rays, or little bony or cartilaginous oſſicles.

FINANCES, in the French polity, ſignify the revenues of the king and ſtate.

FINE, in law, hath divers applications: ſometimes it is uſed for a formal conveyance of lands or tenements, or of any thing inheritable, being *in eſſe tempore finis*, in order to cut off all controverſies. Others define it to be a final agreement between perſons, concerning any lands or rents, &c. of which any ſuit or writ is depending between them in any court.

FINE ſometimes ſignifies a ſum of money paid for entering lands or tenements lett by leaſe; and ſometimes a pecuniary mulct for an offence committed againſt the king and his laws, or againſt the lord of the manor.

FINE *adnullando levato de tenemento quod fuit de antiquo dominico*, is a writ to the juſtices for diſannulling a fine levied of lands holden in ancient demeſne to the prejudice of the lord.

FINE *capiendo pro terris, &c.* a writ lying for one that, upon conviction by a jury, having his lands and goods taken into the king's hands, and his body committed to priſon, obtains favour for a ſum of money, &c. to be remitted his impriſonment, and his lands and goods to be redelivered to him.

FINE *Force*, an abſolute neceſſity that is unavoidable, whereby one is compelled to do any thing.

FINE *levando de tenementis tentis de rege in capite, &c.* a writ directed to the juſtices of the Common-Pleas, to licenſe them to admit of a fine for ſale of lands holden in capite.

FINE *non capiendo pro pulchre placitando*, a writ to inhibit officers of courts to take fines for fair pleading.

FINE *pro rediſſeiſina capienda, &c.* a writ that lies for the releaſe of one laid in priſon for a reſeiſin, upon a reaſonable fine.

FINE *for Alienation*, a reaſonable fine paid the king by his tenants in chief, for licenſe to alienate their lands.

FINERS *of Gold and Silver*, are thoſe who ſeparate theſe metals from coarſer ores. See the article REFINERS.

FINERY, in the iron works, one of the forges at which the iron is hammered and faſhioned into what they call a bloom, or ſquare bar. See the article IRON.

FINE STILLER, in the diſtillery, that branch of the art which is employed on the diſtilling the ſpirit from treacle or other preparations or recrements of ſugar, is called fine-ſtilling, by way of diſtinction from malt-ſtilling; and the perſon who exerciſes this part of the trade is called a fine-ſtiller.

The operation in procuring the ſpirit from ſugar is the ſame with that uſed in making the malt ſpirit; a waſh of the ſaccharine matter being made with water from treacle, &c. and fermented with yeaſt. It is uſual to add, in this caſe, however, a conſiderable quantity of malt, and ſometimes powdered jalap, to the fermenting backs. The malt accelerates the fermentation, and makes the ſpirit come out the cheaper; and jalap prevents any muſty head on the ſurface of the fermenting liquor, ſo as to leave a greater opportunity for the free acceſs of the air, and thus to ſhorten the work, by turning the foamy into a hiſſing fermentation. *Shaw's Lect.*

FINGERS, in anatomy. See HAND.

FINING *of Wines*. See WINE.

FINISHING, in architecture, is frequently uſed for a crowning, acroter, &c. raiſed over a piece of building, to

to terminate, complete, or finiſh it. See the article CROWNING.

FINITE, ſomething bounded or limited, in contradiſtinction to infinite. See the article INFINITE.

FINITOR, in aſtronomy, the ſame with horizon, ſo called becauſe it terminates the ſight or proſpect. See HORIZON.

FINNIKIN, the Engliſh name of a ſpecies of pigeon, remarkable for its wheeling round ſeveral times, whenever it courts the female.

FIRE, a general name, by which men ſeem to underſtand a certain ſenſation or complex notion of light, heat, burning, melting, &c.

The power of fire is ſo great, its effects ſo extenſive, and the manner of its acting ſo wonderful, that ſome of the wiſeſt nations of old reverenced and worſhipped it, as the ſupreme deity. Some of the chemiſts alſo, after they had diſcovered its ſurpriſing operations, ſuſpected it to be an uncreated being: and indeed the moſt famous of them have acknowledged it as the ſource of all their knowledge; and hence have profeſſed themſelves philoſophers by fire, nor thought they could be honoured with a nobler title. Now, amongſt all the wonderful properties of fire, there is none more extraordinary than this, that though it is the principal cauſe of almoſt all the ſenſible effects that continually fall under our obſervation, yet it is itſelf of ſo infinitely a ſubtile nature, that it illudes the moſt ſagacious enquiries, nor ever comes within the cognizance of our ſenſes; and hence others have been led to be of opinion that it ought to be looked upon as ſpirit rather than body. Fire is generally divided into three kinds or ſpecies, viz. celeſtial, ſubterraneous, and culinary.

By celeſtial fire is principally underſtood that of the ſun, without regard to that of the fixed ſtars, though this perhaps may be of the ſame nature.

By ſubterraneous fire we underſtand that which manifeſts itſelf in fiery eruptions of the earth, volcanoes, or burning mountains; or by any other effects it produces in mines, or the more central parts of the earth.

By culinary fire we mean that employed in all chemical operations, and the common occaſions of life.

The ſun's heat appears to be the actuating principle, or general inſtrument of all the operations in the animal, vegetable, atmoſpherical, marine, and mineral kingdoms.

Fire, conſidered in itſelf, ſeems to exiſt, in the greateſt purity and perfection in the celeſtial regions; at leaſt we are inſenſible of any conſiderable ſmoke it yields: for the rays of light come to us from the ſun, unmixed with any of that groſs, feculent, or terreſtrial matter, found in culinary and ſubterranean fires: but, allowing for this difference, the effects of the ſolar fire appear the ſame as thoſe of culinary fire.

If we examine the effects of ſubterraneous fires, we ſhall find them the ſame with thoſe produced by culinary fire. Thus burnt coals, cinders, and melted minerals, are thrown up by Veſuvius and other burning mountains. Warm nephritical exhalations, natural hot ſprings, ſteams, vapours, ſmoke, &c. are found in ſeveral parts of the globe, riſing nearly in the ſame manner as if they were produced by the heat of a furnace. Whence it appears that ſubterraneous fires are of the ſame nature with the culinary.

All the phyſical knowledge we can have of a ſubject, muſt ariſe from attending to its properties and effects: but theſe properties and effects can never be diſcovered without the help of experiments; which in philoſophical enquiries are the only interpreters betwixt the ſenſes and the reaſon: whence all thoſe notions of fire ſhould be rejected as precarious and unſound, that are taken from the direct teſtimony of the ſenſes, or the naked reaſon unaſſiſted by experiments. In this enquiry, therefore, the mind ſhould particularly be kept unpreposſeſſed, and, before it pronounces, wait for full information. As men generally affix to the word fire, a complex idea of burning, light, heat, melting, &c. this idea ſhould be analyſed, in order to ſee what parts are eſſential, and what precarious or arbitrary.

We frequently find the effects of fire produced, where no viſible fire appeared. Thus the fingers are eaſily burnt by an iron heated below the degree of ignition, or ſo as to be no ways viſibly red-hot or fiery: whence it follows, that the eye is no judge of fire.

So likewiſe the touch gives us no poſitive notice of any degree of fire below the natural heat of the body, or any ſo great as to deſtroy the organ.

Again, the effects of fire are often produced without any manifeſt ſigns of burning, melting, &c. as in evaporations, &c. If this method of excluſion and rejection were purſued to its due length, we ſhould, perhaps, find no criterion, infallible mark, or characteriſtic of fire in general, but that of a particular motion ſtruggling among the minute parts of bodies, and tending to throw them off at the ſurface. If this ſhould prove the caſe, then ſuch a motion will be the form and eſſence of fire, and which, being preſent, makes fire alſo preſent; and, when abſent, makes fire alſo abſent: whence to produce, and produce this motion in bodies, will be one and the ſame thing. See ELECTRICITY.

The great and fundamental difference in reſpect to the nature of fire is, whether it be originally ſuch, formed thus by the Creator himſelf at the beginning of things, or whether it be mechanically producible from other bodies, by inducing ſome alterations in the particles thereof. The former opinion is maintained by Homberg, Boerhaave, the younger Lemery, and s'Graveſande; the latter is chiefly ſupported by the Engliſh philoſophers, lord Bacon, Mr. Boyle, and Sir Iſaac Newton.

Bacon, in the treatiſe De Forma Calidi, deduces, from a great number of particulars, that heat in bodies is no other than motion, ſo and ſo circumſtanced; ſo that to produce heat in a body, nothing is required but to excite a certain motion in the parts thereof.

Boyle ſeconds him in an expreſs treatiſe of the mechanical origin of heat and cold, and maintains the ſame doctrine with new obſervations and experiments; as a ſpecimen of which, we ſhall here give the two following:

1. In the production of heat, ſays that able philoſopher, there appears nothing on the part either of the agent or patient, but motion and its natural effects. When a ſmith briſkly hammers a piece of iron, the metal thereby becomes exceedingly hot; yet there is nothing to make it ſo, except the forcible motion of the hammer impreſſing a vehement and variouſly determined agitation on the ſmall parts of the iron, which, being a cold body before, grows, by that ſuper-induced commotion of its ſmall parts, hot: firſt, in a more looſe acceptation of the word, with regard to ſome other bodies, compared with which it was cold before; then ſenſibly hot, becauſe this agitation ſurpaſſes that of the points of our fingers; and in this inſtance oftentimes the hammer and anvil continue cold after the operation; which ſhews that the heat acquired by the iron was not communicated by either of thoſe implements, as heat; but produced in it by a motion, great enough ſtrongly to agitate the parts of ſo ſmall a body as the piece of iron, without being able to have the like effect upon ſo much greater maſſes of metal as the hammer and the anvil: though if the percuſſions were often and briſkly renewed, and the hammer were ſmall, this alſo might be heated: whence it is not neceſſary that a body itſelf be hot to give heat.

2. If a large nail be driven by a hammer into a plank of wood, it will receive ſeveral ſtrokes on its head before it grows hot; but when it is once driven to the head, a few ſtrokes ſuffice to give it a conſiderable heat; for while, at every blow of the hammer, the nail enters further into the wood, the motion produced is chiefly progreſſive, and is of the whole nail tending one way; but when that motion ceaſes, the impulſe given by the ſtroke being unable to drive the nail further on, or break it, muſt be ſpent in making a various, vehement, and inteſtine commotion of the parts among themſelves, wherein the nature of heat conſiſts.

Agreeable to this is the opinion of Sir Iſaac Newton, who conceives that groſs bodies may be converted into light, by the agitation of their particles; and light, again, into groſs bodies, by being fixed therein.

On the other hand, M. Homberg, in his Eſſai du Souffre Principe, holds, that the chemical principle, or element ſulphur, which is ſuppoſed one of the ſimple, primary, pre exiſtent ingredients of all natural bodies, is

is real fire, and conſequently that fire is coeval with bodies.

Dr. s'Graveſande goes on much the ſame principle: fire, according to him, enters the compoſition of all bodies, is contained in all bodies, and may be ſeparated or procured from all bodies, by rubbing them againſt each other; and thus putting their fire in motion: but fire, he adds, is by no means generated by ſuch motion.

Mr. Lemery, the younger, agrees with theſe two authors in aſſerting this abſolute and ingenerable nature of fire: but he extends it farther. Not contented to confine it as an element to bodies, he endeavours to ſhew, that it is equally diffuſed through all ſpace, and that it is preſent in all places; in the void ſpaces between bodies, as well as in the inſenſible interſtices between their parts.

This laſt ſentiment falls in with that of Boerhaave, and the celebrated M. Muſſchenbrock. But notwithſtanding what thoſe able philoſophers have advanced, it is evident that fire, heat, flame, &c. are only the different modifications of the particles of light, and that the particles of light themſelves depend entirely on velocity for their lucific quality; ſince, by many experiments, we know, that the particles of bodies become lucid, or particles of light, by only producing in them a requiſite degree of velocity: thus the particles in a rod of iron, being hammered very nimbly, ſhine and become red hot: thus alſo the violent ſtroke of the flint againſt the ſteel, in ſtriking fire, puts the particles of the ſteel, which it takes off, into ſuch a motion as cauſes them to melt and become ret hot, which makes the ſparks of fire produced by each ſtroke: as, therefore, fire conſiſts in the great velocity of the particles, ſo it may be communicated from one body in which it is, to another in which it is not, after the ſame manner that one body in motion will communicate motion to another that has got none.

Fire differs from heat only in this, that heat is a motion in the particles of a body, with a leſſer degree of velocity; and fire a motion with a greater degree of velocity, viz. ſuch as is ſufficient to make the particles ſhine; though we often call ſuch a ſtate as will burn, fire, tho' it does not actually ſhine; and we ſeldom call thoſe lucid bodies fires, which only ſhine, and do not burn. Theſe are a ſort of phoſphori, which, though they have no heat, yet ſeem to owe their lucidity to the motion of their parts. See the articles HEAT and PHOSPHORUS.

There ſeems to be no other difference between fire and flame, than this; that fire conſiſts in a glowing degree of velocity in the parts of a body, while yet ſubſiſting together in the maſs; but flame is the ſame degree of velocity in the particles diſſipated and flying off in vapour: or, to uſe Sir Iſaac Newton's expreſſion, flame is nothing elſe but a red hot vapour. See the article FLAME.

FIRE, in chemiſtry, the great inſtrument by which moſt of the operations in that art are performed.

The kind, degree, direction, &c. of fire, are things the chemiſt is principally to attend to. There are, in chemiſtry, as many kinds of fire as there are mediums thro' which it may be conveyed, or fuels that afford it. For common uſe, fire is conveyed through aſhes, ſand, water, &c. or directly through the containing veſſel. Hence, fires are denominated of various kinds, as thoſe of ſand, filings of iron, and aſhes, the reverberatory fire, the ignis rotæ, or fire for fuſion, the lamp fire, the balneum mariæ, the vapour bath, and the fire of ſuppreſſion. The chemiſts uſe alſo ſeveral other kinds of heats, which may be claſſed among the fires, ſuch as inſolation, a bath of horſe-dung, a bath of the ſkins of grapes, and the heat of quick-lime.

For the balneum arenoſum, or the fires or baths of ſand, filings of iron, and aſhes, balneum mariæ, balneum vaporis, or vapour-bath, ſee BALNEUM.

The reverberatory fire is made in a furnace covered with a dome, that by this means the heat or flame, which has always a tendency to make its eſcape at the ſuperior parts of the furnace, may be reverberated, or beat back on the veſſel immediately expoſed to it. To expoſe a veſſel to a naked fire, or to diſtil with a naked fire, is when there is no intermediate ſubſtance between the diſtilling veſſel and the fire.

The ignis rotæ, or fire for fuſion, is when a crucible or any other veſſel containing the matter deſtined for fuſion, is ſurrounded with live-coals.

Lamp-fire is when any matter contained in a glaſs-veſſel is rendered hot by the equable heat of a lighted lamp.

Fire of ſuppreſſion is when, in order to diſtil per deſcenſum, the fire is laid above the matter, ſo that the moiſture forced from it, by means of the heat, is precipitated to the bottom of the veſſel; or when the body of the retort, or other veſſel, is covered over with fire.

Inſolation is when any matter deſigned either to be put into fermentation or dried, is expoſed to the heat of the ſun.

The bath of horſe-dung, called alſo the horſe's-belly, is when a veſſel, containing any matter to be either digeſted or diſtilled, is placed in a large heap of horſe-dung.

Bath of the ſkins of grapes, like the bath of horſe's-dung, ſerves for digeſtions or diſtillations; the ſkins are to be collected after the vintage.

The heat of quick-lime moiſtened, may ſerve for ſome diſtillations.

Some differences may be found in the effects produced by theſe different fires, applied in the ſame degree: but they have not, perhaps, been noted as they deſerve. In ſeveral bodies it is evident that dry and moiſt heats have different effects, which we may find remarkably in the common culinary operations of boiling, roaſting, baking, &c. and hence, when the ſame effects are required perfectly ſimilar, the ſame kinds as well as degrees of fire are to be uſed.

The pureſt fire is that of alcohol, or perfectly pure ſpirit of wine; the next in purity is that of diſtilled oils; the next, that of charcoal, or charred turf; and the impureſt, pit coal: but all theſe have nearly the ſame effect, when received through the ſame kind of medium.

Degrees of FIRE. The laſt thing to be conſidered is, how to regulate and aſcertain the degrees of fire in chemical operations, ſo as to produce the effects required in every caſe. The common directions of chemiſts about this matter are full of uncertainty; the firſt, ſecond, third, and fourth degrees of heat, or fire, meaning no preciſe degrees, meaſured by any ſtandard: however, according to Boerhaave, they are as follow.

The firſt degree of fire is that by which nature performs the office of vegetation in plants, and whereby chemiſtry imitates or does the like: this commences from the higheſt degree of cold, which, in Fahrenheit's thermometer, is denoted by one, and ends at eighty degrees; ſince in this whole interval we find certain plants give indications of life and growth. This heat is ſuited to extracting of the native ſpirits of odoriferous vegetables with oils, as that of roſes, jeſſamin, &c. and again, to making the more curious inſolations, &c.

The ſecond degree of fire may be accounted that of the human body, in a healthy ſtate. This degree is always greater than that of the ambient air, and may be ſuppoſed to commence at the 40th degree of the thermometer, and end about the 94th. Within this compaſs animals may live and ſubſiſt, that is, if their juices be of any degree of heat within theſe bounds. This degree is adapted to vinous and acetous fermentation, putrefaction, excluſion of the chick, the finer digeſtions, the making of tinctures and elixirs; and the adepts have uſed it for the firſt digeſtion of their mercury, by carrying the including veſſel conſtantly in their pocket.

The third degree of fire is that which extends from 94 degrees of the thermometer to 212, at which laſt water uſually boils. This degree is required in the diſtillation of ſimple and compound waters, the eſſential oils of vegetables, and will coagulate or conſolidate the ſerum, blood, and other animal juices, and conſequently deſtroy the creatures.

The fourth degree may be taken from 211 to 600 of the thermometer, within which latitude quickſilver or oil of vitriol boils, diſtils, or becomes volatile. This degree is ſuited to the melting of lead, tin, biſmuth, &c. and the ſubliming of ſal armoniac and ſulphur, the calcining of antimony, &c.

The fifth degree is that wherein the other metals melt, and which commences from 600 degrees of the thermometer,

ter, and ends where iron is held in a ſtate of fuſion. In this degree moſt bodies are deſtroyed; but glaſs, gold, ſilver, copper, and iron, remain long unchanged; all other fixed bodies grow red-hot in this degree, and all the unvitrifiable ſtones are calcined.

The ſixth and higheſt degree of fire, hitherto known, is that of the burning lens, or concave, by M. Villette, Tſchirnhauſen, Buffon, and others. The focus of theſe lenſes will even volatilize what is called the metalline or mercurial part of gold, and vitrify the more terreſtrial. See the article BURNING-GLASS.

The fires of ſand, filings of iron, and aſhes, have generally their degrees from the firſt to the third: the reverberatory fire has its degrees from the firſt to the fourth: the ignis rotæ ſerves for calcinations and fuſions; and a veſſel may receive different degrees of heat from a lighted lamp: the balneum mariæ and balneum vaporis have alſo their degrees, as has the fire of ſuppreſſion its degrees: inſolation has its degrees in proportion to the heat of the ſun, to which the ſubſtances are expoſed: the bath of horſe's-dung has its degrees, according to the bulk of the heap, or the place in which it is lodged: the bath of grape-ſkins has alſo its degrees like that of the bath of horſe's-dung: and the heat of quick-lime has alſo its degrees; for according as we deſire it more or leſs ſtrong, we expoſe it to powder longer or ſhorter in the open air; and when we have occaſion for all its heat, we uſe it as quick as we poſſibly can.

FIRE, in medicine. See CAUSTICS.

FIRE, in ſurgery. See CAUTERY.

St. Anthony's FIRE, in medicine. See the article ERYSIPELAS.

Walking FIRE, in meteorology. See WILL-WITH-A-WHISP.

FIRE, in theology. See the articles HELL, CONFLAGRATION, &c.

FIRE, in the art of war, a word of command to the ſoldiers, to diſcharge their muſquets; to the cavalry, to diſcharge their carbines or piſtols; to the grenadiers, to fire their grenadoes; and to the gunners, to fire the guns.

Running FIRE is when a rank of men, drawn up, fire one after another; or, when the lines of an army are drawn out to fire on account of a victory, each ſquadron or battalion takes it from another, from the right of the firſt line to the left, and from the left to the right of the ſecond line.

FIRE-ARMS are all ſorts of arms charged with powder and ball, as cannon, muſquets, carbines, piſtols, blunderbuſſes, &c. See the articles CANNON, GUN, &c.

FIRE-BALL, in the art of war, a compoſition of meal-powder, ſulphur, ſalt-petre, pitch, &c. about the bigneſs of a hand-grenade, coated over with flax, and primed with a ſlow compoſition of a fuſee. This is to be thrown into the enemy's works in the night-time, to diſcover where they are; or to fire houſes, galleries, or blinds of the beſiegers; but they are then armed with ſpikes or hooks of iron, that they may not roll off, but ſtick or hang where they are deſigned to have any effect.

FIRE-LOCK. See GUN, MUSQUET, &c.

FIRE-MASTER, in our train of artillery, an officer who gives the directions and proportions of ingredients for each compoſition required in fire-works, whether for the ſervice of war, or for rejoicings and recreations.

His orders are given to the fire-workers and bombardiers, who muſt execute them.

FIRE-POTS, in the military art, ſmall earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered, then the pot is covered with a piece of parchment, and two pieces of match acroſs, lighted: this pot being thrown where it is deſigned, it breaks and fires the powder, and burns all that is near it, and likewiſe fires the powder in the grenade, which ought to have no fuſe, to the end its operations may be the quicker.

FIRE-WORKERS, officers ſubordinate to the fire-maſter.

FIRE-WORKS. See PYROTECHNIA.

FIRE-BARE, in our old cuſtoms, ſignifies a beacon, or tower, by the ſea-ſide, wherein there were kept continual lights.

FIRE-BOTE is fuel or firing for neceſſary uſe, allowed to tenants, out of the lands granted to them.

FIRE-ENGINE. See the article ENGINE.

Wild-FIRE, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it. It is compoſed of ſulphur, naphtha, pitch, gum, and bitumen; and is only extinguiſhable by vinegar mixed with ſand and urine, or by covering it with raw hides. Its motion or tendency is ſaid to be contrary to that of natural fire, and it always follows the direction in which it is thrown, whether it be downwards, ſideways, or otherwiſe.

Several are of opinion that the ancient Greeks and Romans uſed this fire in their engagements at ſea: whether or not that was the caſe, it was applied againſt the Saracens in a ſea-fight, commanded by Conſtantine Pogonates, in the Heleſpont, and with ſuch effect that he burnt the whole fleet therewith, wherein there were thirty thouſand men.

Electrical FIRE. See ELECTRICITY.

FIRING-IRON, in farriery, an inſtrument not unlike the blade of a knife; which being made red-hot, is applied to a horſe's hams, or other places ſtanding in need of it, as in preternatural ſwellings, farcy-knots, &c. in order to diſcuſs them. Sometimes this is done for wrenches of the paſterns.

FIRKIN, an Engliſh meaſure of capacity, for things liquid, being the fourth part of the barrel: it contains eight gallons of ale, ſoap, or herrings; and nine gallons of beer. See MEASURE and BARREL.

FIRLOT, a dry meaſure uſed in Scotland. The oat-firlot contains 21 ¼ pints of that country; the wheat-firlot contains about 2211 cubical inches; and the barley-firlot 31 ſtandard pints. Hence it appears that the Scotch wheat-firlot exceeds the Engliſh buſhel by 33 cubical inches. See the article MEASURE.

FIRMAMENT, in the old aſtronomy, the eighth ſphere or heaven, with regard to thoſe of the ſeven planets which it ſurrounds. Beſides the diurnal motion, according to Ptolemy, given it by the primum mobile, from eaſt to weſt round the poles of the equator, it has an oppoſite motion to this, from weſt to eaſt upon the poles of the ecliptic, called the ſecondary motion: by this the fixed ſtars advance, according to the order of the ſigns, about one degree in 70 or 72 years. More properly the firmament is that ſpace expanded above us in the heavens.

The word is Latin, *firmamentum*, and derived from *firmus*, ſure, or ſtedfaſt.

FIRMAN is a paſſport or permit granted by the Great Mogul to foreign veſſels, to trade within the territories of his juriſdiction.

FIRMNESS, *Firmitas*, denotes the conſiſtence of a body, or that ſtate wherein its ſenſible parts co-here in ſuch a manner, that the motion of one part induces a motion of the reſt.

FIRST-FRUITS, *Primitiæ*, among the Hebrews, were oblations of part of the fruit of the harveſt, offered to God as an acknowledgement of his ſovereign dominion. The firſt of theſe fruits was offered in the name of the whole nation, being either two loaves of bread, or a ſheaf of barley which was threſhed in the court of the temple. Every private perſon was alſo obliged to bring his firſt-fruits to the temple, and thoſe conſiſted of wheat, barley, grapes, figs, apricots, olives, and dates. They were carried in proceſſion by a company of twenty-four perſons, preceded by an ox, appointed for ſacrifice, his horns gilded, and crowned with olives.

FIRST FRUITS, in the church of England, are the profits of every ſpiritual benefice for the firſt year, according to the valuation thereof in the king's books. See the article ANNATES.

FIR-TREE, *Abies*, in botany, a genus of ever-green trees, whoſe leaves are ſingle, and for the moſt part produced on every ſide of the branches; the male flowers or catkins are placed at remote diſtances from the fruit on the ſame tree; the ſeeds are produced in cones, which are ſquamoſe.

The difference between theſe and the pines is, the latter having two or more leaves produced out of the ſheath or cover.

Theſe trees are all raiſed from ſeeds taken out of their polyſpermous cones. The way to get out the ſeeds is, either by expoſing the cones to a gentle fire, or by ſoaking them all night in water, which will cauſe their ſquamoſe cells to open, and readily emit their ſeeds. The former method is the beſt, provided they are not expoſed to too great heat. But this ought not to be done until you are ready to ſow them; which is beſt performed in the beginning of March.

Theſe plants ſhould be all raiſed in a nurſery, where they may be protected from the birds; otherwiſe they will be in danger of being deſtroyed, when they firſt come up: for as they bring up the huſk of the ſeed on the top of the plant, the birds in picking off the huſk will break off the plant, whereby a whole bed may be loſt in a few hours, if they are not carefully guarded from them.

The beſt time of ſowing theſe ſeeds is about the latter end of March, or the beginning of April, on a bed of light earth, covering the ſeeds about half an inch deep with the ſame ſort of earth. In this bed the plants ſhould remain until the following ſpring, when there ſhould be a number of beds prepared in the nurſery to receive theſe ſeedling plants; and the beginning of April they ſhould be tranſplanted into the beds, at the diſtance of ſix inches row from row, and at three inches aſunder in the rows. If the ſeaſon ſhould prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; and the beds ſhould be covered with mats, to ſcreen the plants from the ſun, and drying winds, until they have taken good root; after which time they will require no farther care, but to keep them clear from weeds. In theſe beds the plants may remain two years; at the end of which they ſhould be tranſplanted into an open ſpot of ground; for their roots will in that time meet quite over the beds.

The diſtance which theſe plants ſhould be placed in this nurſery, ſhould be four feet row from row, and two feet aſunder in the rows.

When the plants are planted, if the ſeaſon ſhould prove dry, they ſhould be watered, to ſettle the earth to their roots; and if this is repeated three or four times, if the ſeaſon ſhould continue dry, it will greatly promote their taking new root, and ſecure them from the injuries of the drying winds. In this nurſery the plants may remain two or three years, according to the growth they ſhall have made; and, during this time, the ground between the plants ſhould be conſtantly kept clean from weeds, and dug between the rows every ſpring; in doing of which, care muſt be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nurſery: and, when they are tranſplanted into the places where they are to remain, the neceſſary care to be taken is, in taking them up, not to injure or cut off their roots, and let them be as little time out of the ground as poſſible; and, when they are out, to guard their roots from the drying winds. The ſureſt time for removing of theſe trees is about the beginning of April; though they may, and often are removed with ſucceſs at Michaelmas, yet the ſpring is the more ſure ſeaſon, eſpecially in moiſt land.

Moſt of the kinds of firs may be removed at the height of ſix or ſeven feet; but thoſe of two feet high are much better, and will in a few years get the better of thoſe taller trees. *Miller's Gard. Dict.*

FISC, *Fiſcus*, in the civil law, the treaſury of a prince.

FISCAL, in the civil law, ſomething relating to the pecuniary intereſt of the prince or people.

FISH, in natural hiſtory, an animal which lives in the water, that being its natural element.

Willoughby, after Ariſtotle, has accurately diſtinguiſhed fiſhes into *cetaceous*, *cartilaginous*, and *ſpinous*.

The *cetaceous*, called alſo *bellua marinæ*, have lungs, and breathe like quadrupeds; they copulate alſo like them, and conceive and bring forth their young alive, which they afterwards ſuckle with their milk.

The *cartilaginous* ſort are thoſe produced from eggs like large birds; which are alſo excluded the womb like thoſe of birds.

The *ſpinous* kind are alſo oviparous; but their eggs are ſmaller, and they have ſpinæ up and down in their fleſh to ſtrengthen them.

The ſame author is likewiſe of opinion that it would be alſo proper to divide fiſhes into ſuch as breathe with lungs, and ſuch as breathe with gills; and then to ſubdivide thoſe that breathe with gills into viviparous and oviparous.

Naturaliſts remark that the ſtructure of fiſhes, and their confirmation to the element they reſide in, is very wonderful. Their bodies are cloathed and guarded in the beſt manner, with ſcales or ſhells, ſuitable to their reſpective circumſtances, the danger they are expoſed to, and the motion and buſineſs they are to perform. The center of gravity is placed in the propereſt part of the body for ſwimming; and their ſhape the beſt adapted to their making their way through the water, and moſt conformable to the rules of geometry. They have ſeveral parts peculiar to themſelves; as fins to balance and keep them upright, and an air-bladder to enable them to riſe or ſink at pleaſure. They have gills or branchiæ, whereby they reſpire, as animals do by the lungs. The tail is the inſtrument of progreſſive motion, and ſerves to row them forward. Their eyes are peculiarly formed to enable them to correſpond with all the conveniencies and divergencies of rays, which the variations of the watery medium, and refractions thereof, may occaſion; in which reſpect they bear a near reſemblance to birds.

FISH, among ſeamen, a machine for drawing up the flooks of the anchor to the davit. See the article DAVIT.

It is compoſed of four parts, viz. the hook, the pendant, the block, and the tackle.

The pendant is a piece of ſtrong rope paſſing through the block, hung over the end of the davit, which projects out from the forecaſtle to keep the anchor at a diſtance from the ſhip's ſide, that the flooks may not tear it as they are drawn up: at one end of the pendant is faſtened the hook, which is of ſufficient ſtrength and capacity to grapple the flooks under water, and ſuſtain their weight: at the other end of the pendant is fixed the tackle, which is a complication of pullies, to perform this operation.

FISHES *of the Maſt*, certain pieces of wood hollowed on one ſide, and convex on the other, faſtened ſecurely on the maſts of a ſhip to ſtrengthen them, either when it is apprehended there is a neceſſity for this additional ſupport to bear an extraordinary preſſure of ſail; or after they may have ſuſtained ſome damage from a former occaſion.

FISH-PONDS, thoſe made for the breeding or feeding of fiſh.

Fiſh-ponds are no ſmall improvement of watery and boggy lands, many of which are fit for no other uſe. In making of a pond, its head ſhould be at the loweſt part of the ground, that the trench of the flood-gate or ſluice, having a good fall, may not be too long in emptying. The beſt method of making the head ſecure, is to drive in two or three rows of ſtakes above ſix feet long, at about four feet diſtance from each other, the whole length of the pond-head, whereof the firſt row ſhould be rammed at leaſt about four feet deep. If the bottom is falſe, the foundation may be laid with quick-lime, which ſlacking, will make it as hard as a ſtone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and ſtakes; and when theſe are well covered, drive in others, as they ſee occaſion, ramming in the earth as before, till the pond-head be of the height deſigned.

The dam ſhould be made ſloping on each ſide, leaving a waſte to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepeſt part need not exceed ſix feet, riſing gradually in ſhoals towards the ſides, for the fiſh to ſun themſelves, and lay their ſpawn. Gravelly and ſandy bottoms, eſpecially the latter, are beſt for breeding; and a rich ſoil with a white fat water, as the waſhing of hills, commons, ſtreets, ſinks, &c. is beſt for fattening all ſorts of fiſh. For ſtoring a pond, carp is to be preferred for its goodneſs, quick growth, and great increaſe, as breeding five or ſix times a year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds

that have marl or clay bottoms, with plenty of weeds and graſs, whereon they feed in hot months.

Your pond ſhould be drained every three or four years, and your fiſh ſorted. If it is a breeding one, the ſmaller ones are to be taken out to ſtore other ponds with, leaving a good ſtock of females, at leaſt eight or nine years old, as they never breed before that age. In feeding ponds it is beſt to keep them pretty near of a ſize.

FISHERY, a place where great numbers of fiſh are caught.

The principal fiſheries for ſalmon, herring, mackrel, pilchards, &c. are along the coaſts of England, Scotland, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the Eaſt and Weſt Indies.

FISHERY denotes alſo the commerce of fiſh, more particularly the catching them for ſale.

FISSURE, *Fiſſura*, a chap or crack, in ſurgery, is either natural or morbid: thus, the mouth, &c. is frequently called a natural fiſſure: morbid fiſſures are either thoſe of the cranium or other bones, or chaps of the ſkin, which ſometimes happen about the lips, anus, and other parts of the body.

The word is Latin, *fiſſura*, and derived from *findo*, to ſplit or cleave.

FISSURE, in philoſophy, is frequently applied to thoſe diviſions that are to be met with between layers of different kinds of earth or ſtone.

FISTULA, in ſurgery, a deep, narrow, and callous ulcer, generally ariſing from abſceſſes or ulcers.

The word is Latin, and literally ſignifies a pipe; this diſorder being ſo called from its reſemblance to a pipe or reed.

The ſeat of a fiſtula is always in the membrana adipoſa; nor have we any well vouched obſervations of fiſtulas penetrating what we properly call the ſubſtance of the muſcles. But if we conſider that pus, collected in the membrana celluloſa, and attenuated therein, may be lodged upon the muſcles, it is obvious that this pus muſt, by the action of theſe muſcles, be propelled through all the adjacent parts, and produce deep ſinuſes and fiſtulas of the worſt kind, eſpecially when it inſinuates into the inteſtines of the muſcles: the thicker, therefore, the membrana adipoſa is, or the more ſtrata of muſcles that lie in the ſuppurated part, the more miſchief the retained pus may do.

When there is an external aperture on the ſurface of the body, a ſinus or fiſtula may be eaſily diſcovered. Celſus informs us, that it is above all things highly expedient to introduce a probe into the fiſtula, to know its depth and its direction; whereby we may know whether it has penetrated to the bone or not; and whether the bone is carious or ſound. But the beſt method of diſcovering them is with a ſyringe to inject tepid water, which will eaſily inſinuate into all their windings.

But when ſinuſes are not yet opened, they are with greater difficulty diſcovered, eſpecially when deep ſeated. All the light we can then receive is from the ſymptoms of the preceding inflammation, and the nature of the ſubſequent ſuppuration; beſides, that no conſiderable ſuppuration can happen without being ſoon after accompanied with a ſlight hectic fever.

When fiſtulas, not yet become callous, are complicated with ulcers, and diſcovered either by the eye, the aſſiſtance of the probe, or any other means, the moſt expeditious method of relief is to make an inciſion to the very bottom, if it can be done without danger, after which they are to be deterged and conſolidated. But, becauſe patients are unwilling to ſubject themſelves to this operation, it is expedient previouſly to cleanſe them by ſome proper injection, or by means of lint covered with ſome digeſtive ointment. As the hardneſs of tents thruſt into fiſtulas, or perhaps their too great length, may produce a callous, or inflammation, or excite a commotion of the humours, or at leaſt protract the cure, I do not think the uſe of tents ſafe: Belloſte and Cæſar Magatus, both ſkilful ſurgeons, having, on this account, entirely rejected them; only in caſes where the conglutination of the mouth of narrow fiſtulas is to be prevented; and even then they ought to be very ſhort and ſoft. Belloſte abſolutely diſcards not only all tents but injections.

Another ſtep in the cure of fiſtulas is duly to preſs their bottoms towards their orifices or apertures: for this purpoſe, a narrow compreſs, or ſlip of plaſter in that form, is, after the ulcer is cleanſed, and proper medicines put into the fiſtula, to be applied to its bottom, and ſecured with lint, plaſters, and bandage. It is moſt expedient to apply the bandage firſt to the bottom of the fiſtula, or at leaſt make it tighteſt there, that the peccant matter may be propelled from the bottom to the mouth of the fiſtula, whereby the bottom will be conglutinated before the reſt of the fiſtula. This generally happens ſooner in fiſtulas of the arms or legs, than in thoſe of other parts, eſpecially if their bottoms lie towards the ſuperior and their mouths towards the inferior parts of the members.

When fiſtulas lie too deep to have their moſt remote cavities commodiouſly cleanſed, detergent medicines are to be injected to waſh out the ſordes; ſuch as decoctions of agrimony or birthwort, mixed with honey of roſes, or eſſence of myrrh and aloes; or, which Belloſte greatly commends, a decoction of the leaves of the walnut-tree, with an admixture of ſugar.

But, if the method of cure already directed ſhould prove inſufficient both for cleanſing and conglutinating fiſtulas, greater relief is generally obtained from manual operation, eſpecially when the fiſtulas are directed downwards, or too winding, or when their bottoms cannot be ſufficiently compreſſed: and, in theſe caſes, an inciſion is to be made from their mouths to their very bottoms.

Some grooved probe is, therefore, to be gently paſſed into the cavity of the fiſtula, and introducing a knife into the groove, as much of the ſkin and fleſh is to be cut, as is thought ſafe or ſufficient to anſwer the end; that not only the corrupted matter may be more expeditiouſly diſcharged, but medicines more commodiouſly applied.

If, upon making an inciſion into a fiſtula, a large quantity of blood ſhould be diſcharged, the wound is, in the firſt dreſſing, to be filled with dry lint, and duly dreſſed: then a digeſtive ointment, in conjunction with the Egyptian ointments, or red precipitate, is to be applied till the ulcer is ſufficiently deterged. The other meaſures to be taken are the ſame as in recent ulcers. *Heiſter's Surgery.*

FISTULA *in Ano*, in ſurgery, an abſceſs running upon or into the inteſtinum rectum; though an abſceſs in this part, when once ruptured, does generally, if neglected, grow callous in its cavity and edges, and becomes, at laſt, what is properly called a fiſtula.

That the anus is ſo often expoſed to this malady, in any criſis of the conſtitution, is chiefly aſcribed to the depending ſituation of the part; but what very much conduce to it likewiſe, are the great quantities of fat ſurrounding the rectum, and the preſſure the hæmorrhoidal veſſels are liable to, which, being ſuſtained upon very looſe membranes, will be leſs able to reſiſt any effort, that nature ſhall exert, to fling off a ſurcharge; and from one ſtep to another, that is, from inflammation to ſuppuration, lead on to the diſtemper we are treating of.

That the fat is the proper ſubject of abceſſes, may be learned from an inflammation of the ſkin affecting the membrana adipoſa, and producing matter there; in which caſe, a ſuppuration runs from cell to cell, and in a few days lays bare a great quantity of fleſh underneath, without affecting the fleſh itſelf: nay, I think it may be doubted, whether, in thoſe abſceſſes which are eſteemed ſuppurations of the muſcles, the inflammation and matter are not abſolutely firſt formed in this membrane, where it is inſinuated between the interſtices of their fibres.

The piles, which are little tumours formed about the verge of the anus, immediately within the membrana interna of the rectum, do ſometimes ſuppurate, and become the forerunners of a large abſceſs; alſo external injuries here, as in every other part of the body, may produce it; but, from whatever cauſe the abſceſs ariſes, the manner of operating upon it will be according to the nature and direction of its cavity.

If the ſurgeon has the firſt management of the abſceſs, and there appears an external inflammation upon one ſide of the buttock only; after having waited for the proper maturity, let him, with a knife, make an inciſion the whole

whole length of it; and, in all probability, even though the bladder be affected, the largeneſs of the wound, and the proper application of doſſils lightly preſſed in, will prevent the putrefaction of the inteſtine, and make the cavity fill up like impoſthumations of other parts.

If the ſinus is continued to the other buttock, almoſt ſurrounding the inteſtine, the whole courſe of it muſt be dilated in like manner; ſince, in ſuch ſpongy cavities, a generation of fleſh cannot be procured but by large openings; whence alſo, if the ſkin is very thin, lying looſe and flabby over the ſinus, it is abſolutely neceſſary to cut it quite away, or the patient will be apt to ſink under the diſcharge, which, in the circumſtance here deſcribed, is ſometimes exceſſive. By this method, which cannot be two much recommended, it is amazing how happy the event is likely to be; whereas, from neglecting it, and truſting only to a narrow opening, if the diſcharge does not deſtroy the patient, at leaſt the matter, by being confined, corrupts the gut, and, inſinuating itſelf about it, forms many other channels, which, running in various directions, often baffle an operator, and have been the cauſe of a fiſtula being ſo generally eſteemed very difficult of cure.

Here I have conſidered the impoſthumation as poſſeſſing a great part of the buttock; but it more frequently happens, that the matter points with a ſmall extent of inflamation on the ſkin, and the direction of the ſinus is even with the gut: in this caſe, having made a puncture, you may, with a probe, learn if it has penetrated into the inteſtine, paſſing your finger up it, and feeling the probe introduced through the wound into its cavity; though, for the moſt part, it may be known by a diſcharge of matter from the anus. When this is the ſtate of the fiſtula, there is no heſitation to be made, but, immediately putting one blade of the ſciſſars up the gut, and the other up the wound, ſnip the whole length of it. This proceſs is as adviſeable when the inteſtine is not perforated, if the ſinus is narrow, and runs upon or very near it; for, if the abſceſs be tented, which is the only way of dreſſing it, while the external orifice is ſmall, as I have here ſuppoſed, it will almoſt certainly grow callous; ſo that the ſureſt means of cure will be opening the gut, that proper applications may be laid to the bottom of the wound. However, it ſhould be well attended to, that ſome ſinuſes, pretty near the inteſtine, neither run into nor upon it, in which caſe they muſt be opened, according to the courſe of their penetration. There are abundance of inſtances, where the inteſtine is ſo much ulcerated as to give free iſſue to the matter of the abſceſs by the anus; but I believe there are none where there is not, by the thinneſs and diſcolouration of the ſkin, or an induration to be perceived through the ſkin, ſome mark of its direction; which, if diſcovered, may be opened into with a lancet, and then it becomes the ſame caſe as if the matter had fairly pointed.

If the ſinuſes into and about the gut are not complicated with an induration, and you can follow their courſe, the mere opening with ſciſſars, or a knife guided on a director, will ſometimes ſuffice; but it is generally ſafer to cut the piece of fleſh, ſurrounded by theſe inciſions, quite away, and, when it is callous it is abſolutely neceſſary, or the calloſities muſt be waſted afterwards by eſcharotic medicines, which is a tedious and cruel method of cure.

When the fiſtula is of long ſtanding, and we have a choice of time for opening it, a doſe of rhubarb the day before the operation will be very convenient, as it not only will empty the bowels, but alſo prove an aſtringent for a while, and prevent the miſchief of removing the dreſſings in order to go to ſtool.

It ſometimes happens that the orifices are ſo ſmall as not to admit the entrance of the ſciſſars, in which caſe ſponge tents muſt be employed for their dilation.

In performing theſe operations on the anus, I do not think, in general, any inſtrument ſo handy as the knife and ſciſſars: almoſt all the others which have been invented to facilitate the work, are not only difficult to manage, but more painful to the patient: however, in thoſe inſtances where the fiſtula is very narrow, and opens into the inteſtines, juſt within the verge of the anus, the ſyringotomy may be uſed with advantage: but, when the opening into the gut is high, it cannot be employed without giving great pain. I do not caution againſt cutting the whole length of the ſphincter, experience having ſhewn it may be done with little danger of an incontinence of excrement; and, in fact, the muſcle is ſo ſhort, that it muſt generally be done in dilatations of the inteſtine.

The worſt ſpecies of fiſtula, is that communicating with the urethra, and ſometimes, through the proſtrate glands, with the bladder itſelf. This generally takes its riſe from a former gonorrhœa, and appears externally firſt in peritonæo, and afterwards increaſing more towards the anus, and even ſometimes into the groin, burſts out in various orifices, through the ſkin, which ſoon become callous and rotten; and the urine paſſing partly through thoſe orifices, will often excite as much pain, and of the ſame kind, as a ſtone in the bladder.

This ſpecies of fiſtula, taking its uſe from ſtrictures of the urethra, is only manageable by the bougie: for, ſo long as the urethra is obſtructed, the cure of the fiſtula will be imperfect; but, if the canal is opened by this application, it is amazing what obſtinate indurations and foul ſinuſes will in conſequence diſappear; though there are ſome ſo callous and rotten, as to demand the knife and skilful dreſſings, notwithſtanding the urethra ſhould be dilated by the uſe of bougies. *Sharpe's Surgery.*

FISTULA LACHRYMALIS, a diſeaſe which attacks the great caruncle in the inward corner of the eye. See the article EYE.

The firſt degree of this diſeaſe ſtops up the natural paſſage of the tears, and forces them to run down the cheek; the ſecond is when pus is mixed with the tears, which proceeds ſometimes from an opening in the skin, between the noſe and the great corner of the eye; the laſt is when the pus has not only corroded the neighbouring parts, which are ſoft, but has affected the bone which lies underneath. This laſt ſort of fiſtula ſometimes turns cancerous, and Riverius adviſes not to meddle with it at all.

Whatever may be the cauſe of this diſorder, whether the ſmall-pox, or French diſeaſe, it always ſtops up the naſal conduit.

If the abſceſs is not open, a time muſt be choſen when it is fulleſt of pus. For this reaſon, the eye of the patient muſt be cloſed, and ſmall long pieces of plaſter muſt be put one upon another, acroſs the eye-lids, from the puncta lachrymalia to the great angle of the eye. The ſuperior branches of the canal being thus compreſſed, that nothing can paſs that way, it will be amaſſed in the ſack, and a place proper for an inciſion ſhould then be pointed out. If the abſceſs is already open, the orifice and the probe will ſhew where it is to be dilated, which muſt be done by the biſtoury, both above and below, from the ſuperior part of the ſack to the edge of the orbit. The ſack being opened, it muſt be filled with dry lint, which may be taken away next day, and a pledgit dipt in a mild digeſtive applied, which muſt be repeated once or twice a day, according to the quantity of ſuppuration: when the ſuppuration begins to diminiſh at every dreſſing, a ſmall probe muſt be introduced into the naſal canal, to dilate it a little, and to leave a paſſage for the tears and the pus.

This method muſt be continued till the ſuppuration is almoſt ended, then it may be dreſſed ſuperficially, with dry lint, or with a deſiccative, which will complete the cure: after which it will be proper to wear a compreſſing bandage a few weeks longer to prevent its return. When the bone lies open, and it is neceſſary to penetrate into it, you muſt direct the inſtrument towards the noſe, and not towards the naſal canal, for fear of entering the ſinus maxillaris.

FISTULAR, or FISTULOUS, appellations given by ſurgeons to wounds and ulcers, which degenerate into fiſtulas. See the article FISTULA.

FISTULAR, among botaniſts, is applied to leaves and flowers that are tubular, or reſemble a hollow pipe.

FIT, in medicine, denotes much the ſame with paroxyſm. See PAROXYSM.

FITS *of eaſy Reflection and Tranſmiſſion*, in optics. See the articles REFLECTION and TRANSMISSON.

FITCHEE, in heraldry, a term applied to a croſs, when the lower end of it is ſharpened into a point.

FITTING-OUT, in the ſea-language, the act of providing a ſhip with a ſufficient number of men to navigate her; alſo with proviſions of all ſorts, artillery, ammunition, maſts, yards, ſails, cordage, anchors, and other furniture: alſo the rigging and ſecuring her maſts againſt the dangers of the wind and ſea.

FIXATION, in chemiſtry, the rendering any volatile ſubſtance fixed, ſo as not to fly off upon being expoſed to a great heat; hence,

FIXED BODIES are thoſe which bear a conſiderable degree of heat without evaporating, or loſing any of their weight.

FLACCIDITY, among phyſicians, a diſorder of the ſolids, cured by aſtringent and cardiac medicines, joined with exerciſe and good air.

FLAG, in the ſea-language, the banners or colours by which an admiral is diſtinguiſhed at ſea.

FLAGS *in the Britiſh Navy*, are either red, white, or blue; and they are hoiſted either at the heads of the main-maſt, fore-maſt, or mizen-maſt.

Flags, when diſplayed from the top of the main-maſt, are the diſtinguiſhing marks of admirals; when from the fore-maſt of vice-admirals; and when from the mizen-maſt, of rear-admirals.

The higheſt flag in the Britiſh navy is the anchor and rope, which is only diſplayed when the lord-high admiral or lords commiſſioners of the admiralty are aboard; the next is the union, the diſtinction peculiar to the ſecond officer, called admiral of the fleet; and the loweſt flag is the blue at the mizen-maſt.

FLAGELLANTES, WHIPPERS, in church hiſtory, certain enthuſiaſts in the thirteenth century, who maintained that there was no remiſſion of ſins without flagellation, or whipping. Accordingly they walked in proceſſion, preceded by prieſts carrying the croſs, and publicly laſhed themſelves, till the blood dropped from their naked backs.

FLAGEOLET, or FLAJEOLET, a little flute, uſed chiefly by ſhepherds and country people. It is made of box, or other hard wood, and ſometimes of ivory, and has ſix holes beſides that at the bottom, the mouth-piece, and that behind the neck. See FLUTE.

FLAIL, an inſtrument for threſhing corn. See CORN and THRESHING.

FLAKE, among gardeners, a kind of ſtriped carnations, with only two colours.

FLAMBEAU, a kind of large taper, made of hempen wicks, by pouring melted wax on their top, and letting it run down to the bottom. This done, they lay them to dry; after which they roll them on a table, and join four of them together by means of red-hot iron; and then pour on more wax, till the flambeau is brought to the ſize required.

FLAME, *Flamma*, in phyſiology, the ſmall parts of an inflammable or conſiderably unctuous body, that are ſet on fire, or briſkly agitated and thrown off, with a certain vibrative motion at the ſurface of that body into the open air: or, in Sir Iſaac Newton's words, the flame of a body is only the ſmoke thereof heated red-hot; and the ſmoke is only the volatile part of the body ſeparated by the fire. See FIRE and SMOKE.

FLAMEN, in Roman antiquity, the name of an order of prieſts, inſtituted by Romulus or Numa; authors not being agreed on this head.

They were originally only three, viz. the flamen dialis, flamen martialis, and flamen quirinus. They were choſen by the people, and inſtalled by the ſovereign pontiff: afterwards, their number was increaſed to fifteen; the three firſt of whom were ſenators, and called flamines majores; the other twelve, taken from among the people, being denominated flamines minores.

The flamen dialis, or prieſt of Jupiter, was a conſiderable perſon at Rome; the flamen martialis, or prieſt of Mars, was the ſecond in dignity; and the flamen quirinalis, was the next to him.

The greater flamens wore the robe edged with purple, like that of the greater magiſtrates, had an ivory-chain, and ſat in the ſenate. They wore a little band of thread, filamen, about their head; from whence, according to Varro, they had their name.

FLANCH, FLANQUE, or FLASQUE, in heraldry, an ordinary always borne double, being the ſegment of a circular ſuperficies.

FLANDERS, a province of the Netherlands, bounded by the German ſea and the United Provinces, on the north; by the province of Brabant, on the eaſt; by Hainault and Artois, on the ſouth; and by another part of Artois and the German ſea, on the weſt; being about ſixty miles long, and fifty broad, and divided between the Auſtrians, the French, and the Dutch.

Flanders is a perfectly champaign country, with not a riſing ground or hill in it, and watered with many fine rivers and canals. Its chief commodities are fine lace, linen, and tapeſtry.

FLANNEL, or FLANEL, a looſe ſort of woollen ſtuff not croſſed, and wove on a loom with two treddles, like bays.

FLANK, in the menage, the ſide of a horſe between the ribs and haunches.

FLANKS *of an Army*, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

FLANK *of a Baſtion*, in fortification, that part which joins the face to the curtain. See the article BASTION.

Oblique FLANK, or *Second* FLANK, that part of the curtain from whence the face of the oppoſite baſtion may be diſcovered.

Retired FLANK, or *Low* FLANK, or *Covered* FLANK, one of the platforms of the cazemate. See the article CAZEMATE.

Theſe retired flanks are a great defence to the oppoſite baſtion, and to the paſſage of the moat, becauſe the beſiegers cannot ſee nor eaſily diſmount their guns. The curtain is eſteemed the ſtrongeſt part of a fortification, becauſe flanked at both ends; and the face is accounted the weakeſt, as having only one defence from the oppoſite flank.

FLANKED ANGLE, in fortification, that formed by the two faces of a baſtion.

FLANKING ANGLE, or *Angle of the* TENAILLE, that compoſed of the two lines of defence, and pointing towards the curtain. See the article TENAILLE.

FLANKING *Line of Defence*. See the article LINE *of Defence*.

FLATS, in muſic, a kind of additional notes, which, together with ſharps, ſerve to remedy the defects of muſical inſtruments, wherein temperament is required. See TEMPERAMENT and SHARP.

FLATULENCY, in medicine, a diſorder of the bowels ariſing from a weak ſtomach, and crude flatulent aliment, as peaſe, beans, lentils, coleworts, hard fat fleſh, &c. which degenerate into wind, creating great anxiety if not evacuated, and difficulty of breathing.

Another cauſe of flatulencies are congeſtions of blood in the branches of the vena porta; whence proceed anxieties of the præcordia, difficult breathing, colic pains, heart-burn, head-achs, vertigo, and watchfulneſs.

If the flatulency ariſes from crudities in the ſtomach, evacuations are firſt of all neceſſary; after which may be given bitters, aromatics, carminatives, and ſtrengtheners, with a ſpare diet and exerciſe. If it proceeds from congeſtions of blood, as is the caſe of hypochondriacs, a vein muſt be opened; and if the body is coſtive, an emollient clyſter or a gentle laxative will be proper. If theſe fail, chalybeate medicines are to be called in, as tincture of vitriol of iron, ſteel-filings finely powdered, from ſix to ten grains, or oil of cinnamon with ſugar or bitters, ſpaw-waters, and conſtant exerciſe.

FLAX, *Linum*, in botany, a plant from which linen is manufactured.

There are ſeveral ſpecies of this plant, which are preſerved in ſome curious gardens of plants for variety ſake; but, as they are of little uſe or beauty, it would be needleſs to expatiate on them in this place.

The linum ſativum, or manured flax, is that which is cultivated for uſe in divers parts of Europe, and is reckoned an excellent commodity: the right tilling and ordering of which is eſteemed a good piece of huſbandry.

This ſhould be cultivated upon a rich ſoil that has not been ploughed for ſeveral years, upon which flax always makes the beſt improvement: but, as it draws greatly from the ſoil, it ſhould not be ſown two years together

upon the ſame ground. The land muſt be well ploughed, laid flat and even, upon which the ſeeds ſhould be ſown about the middle of March, when the weather is mild and warm. During the ſpring, you muſt carefully weed it; which if neglected, eſpecially in a moiſt ſeaſon, the weeds will over-grow and deſtroy the crop. There are ſome perſons who recommend the feeding of ſheep with flax, when it is a good height; and ſay, they will eat away the weeds and graſs, and do the flax good; and if they ſhould lie in it, and beat it down, or flatten it, the next rain that falls it will riſe again: but this muſt not be practiſed but in a moiſt ſeaſon, and upon a rich ſoil; for if the ground be poor, or the ſpring dry, it will not riſe again to any conſiderable height.

The beſt ſeed is that which comes from the Eaſt country, and is known by the name of Riga flax; for if the Engliſh ſeed be ſown three or four times, it is very apt to degenerate. If the ſeed be good, two buſhels will be enough to ſow an acre; but if it be but middling, there ſhould be a greater allowance. Towards the latter end of Auguſt the flax will begin to ripen, when you muſt be careful that it grow not over ripe; therefore you muſt pull it up as ſoon as the heads begin to change brown, and hang downwards, otherwiſe the ſeeds will ſoon ſcatter, and be loſt; ſo that the pluckers muſt be nimble, and tie it up in handfuls, ſetting them upright till they be perfectly dry, and then houſe them. If the flax be pulled when it firſt begins to flower, it will be whiter and ſtronger than if it ſtand till the ſeed is ripe; but then the ſeed will be loſt.

This is a plant of the greateſt uſe in ſeveral of the moſt eſſential parts of life: from the ſeeds an expreſſed oil is drawn, which is of great uſe in medicine, painting, &c. from the bark of the ſtalks is made linen, and from the rags of linen is made paper: ſo that this plant may be eſteemed as one of the moſt valuable and neceſſary in many of the principal conveniencies of life. *Miller's Gard. Dict.*

This plant has a more oily taſte than mallow, and is the chief of the emollient tribe. The ſeeds afford an excellent medicine, ſince from them is expreſſed an oil, which is anodyne, demulcent, and extremely adapted to all manner of aſperities; it relaxes, and diſſolves acridities, whence it is of extraordinary ſervice in the moſt deſperate cholics. The ſtiff and rigid limbs, being anointed with this oil, are relaxed and rendered flexible. This oil, when freſh drawn, and taken at the mouth, is very good in a pleuriſy, and a cough, to help expectoration; and, injected in clyſters, is very proper in the hæmorrhoids, and indurated fæces, whence proceeds the cholic; mixed with ſealed and japan earth, it is a great arcanum in the dyſentery: an emulſion of the ſeeds is of ſervice in the pleuriſy and peripneumony; the oil is a very good remedy againſt the ſtone: the ſeeds reduced to a meal, and boiled and prepared in the form of a cataplaſm, are applied to tumors and abſceſſes, in order to mollify and ripen them. The ſeed, boiled in water, makes a mild oily decoction, preſcribed to be drank as an anodyne in inflammations of the ſmall inteſtines, the diarrhœa, the dyſentery, nephritic pains, and retention of urine. The oil, boiled with honey, clears the face and ſkin of ſpots, and all cutaneous blemiſhes. The leaves are emollient, and the ſmell of the flowers is not poiſonous, as ſome authors have written. To cloſe all, we ſhall obſerve, that whereas cotton can never be uſed about wounds, on account of its denticulated parts, which diſpoſe to inflammations; linen, the manufactured produce of this plant, is, by its extraordinary ſoftneſs, ſmoothneſs, and flexibility, of all other things, the beſt adapted to ſuch purpoſes. *Hiſt. Plant. aſcript. Boerhaave.*

As it is agreed that the lighteſt loams and the thickeſt crop afford the fineſt flax, it may be of uſe to let the farmer know how he may ſave ſuch crops from lodging, as they generally do. The method is a little expenſive; but if it anſwers, it will quit coſt very well. When the flax is in the ground, divide your field into equal ſquares, the ſides of which may be four or five feet long; and at each angle thruſt a forked ſtick ſteady in the ground. When your flax is ſome inches high, lay from ſtick to ſtick a light croſs pole; and this will ſupport the flax, and hinder it from lodging. Some uſe ropes inſtead of poles; but they yield too much, and anſwer but imperfectly.

High winds are ſo common in this country, that there is reaſon to apprehend, that the Dutch method of laying flax looſe upon the ground would be attended with conſiderable inconveniency. The following method is much ſafer: tie gently each handful as cloſe as may be to the heads; and then, ſpreading out the ends, ſet it upright on the ground. Three or four of theſe, together, make one ſtook; and into ſuch ſmall ſtooks divide all the flax you have. They dry ſoon, becauſe the wind has free acceſs to the ſtalks, as the ſun has to the heads, and the rain cannot lodge in any quantity upon them.

Rippling comes next. Two men may work at every inſtrument, by fixing it on a bench, that one may ſit at either end. Let them take ſmall handfuls at a time, and draw the flax through the ripple without violence. Two women to each bench are neceſſary to hand the flax in bundles to the ripplers, to receive it from them again, to ſort it according to their ſeveral degrees of length, ſtrength, ripeneſs, and fineneſs, and to tie it looſely in little ſheaves.

After rippling, the ſeed muſt be carried to the granary, and the flax laid down to water. If poſſible, diſpoſe of the whole into your ponds together. The ſummer, which draws haſtily towards an end, is your fitteſt ſeaſon, and ſhould be huſbanded with care: however, let nothing tempt you to uſe bog-holes and running waters. It is better to delay to the next ſeaſon, than diſcolour or damage all your flax.

Cover your flax, to keep it down, with your ſlutch or mire at the bottom of your ponds, or, till that be gathered in ſufficient quantities, with clay, ruſhes, fern, or timber. From four to twelve or thirteen days is the time requiſite for watering. After the fourth, examine your flax daily, and be particularly careful not to let it lie too long. It is a miſtake, on the ſafer ſide, to draw it off the ſooneſt.

In graſſing, the ſhorteſt graſs ſhould be preferred. Dry ſand-banks do well. On either the flax muſt be turned every ſecond day, and generally lies from a fortnight to three weeks.

To dry your flax, heat your oven thoroughly; then let it cool, till a man can ſtand in it without uneaſineſs; fill it over night, and your flax will be ready for the break next morning. The dirt and ſtraws ſcutched out of the flax, in one day, will heat the oven for the next.

When you break your flax, take ſheaf by ſheaf out of the oven, as you uſe it: it comes criſp under the engine, works the better and more eaſily. It is an error to lay the flax, as we do, as far as may be from the joint. The nearer it is placed to the center of motion in the break, the more readily it ſplits, and the leſs damage it receives.

In ſcutching, chuſe the broad round ſcutch: the ſquare and narrow one, in uſe among us, cuts and deſtroys the flax.

By the time the flax is ſcutched, and about the middle of October, it will be time to threſh the ſeed.

This may be done by driving horſes backwards and forwards on the bows, or by drawing over them a heavy rolling-ſtone upon a ſmooth hard floor.

Cleaning it requires more nicety. To do it thoroughly, it muſt firſt go through the winnow, which ſeparates it from the bows; through the riddle next, to take out ſtraws, ſtones, and larger dirt; then ſucceſſively through two different ſieves; the firſt bored with oval holes, to let through the ſeed and nothing elſe of greater bulk; the ſecond cloſer, to retain the ſeed, and afford a paſſage to all ſmaller bodies; and laſtly, through the ſcreen or wire-harp, which frees it from all duſt. When the flax-dreſſer has thus cleaned his ſeed, he ſhould return to his flax, and put it through the fining-mills. The wheel in theſe turns alternately from right to left, and from left to right, twice each way; and, according to the number of theſe double turns, the flax comes out the finer, the ſmoother, and the ſofter. Fourſcore ſuch turns is the moſt that any flax requires, and probably as much as it will bear.

N B. For want of theſe fining-mills in Scotland, beating of flax is directed.

In hackling, women and children ſhould be employed from choice. They work with greater gentleneſs than men; and care and tenderneſs are the main excellencies

in

in this buſineſs. For the beſt flax, four ſets of hackles will be requiſite, each of them of a different fineneſs: through theſe it may be drawn ſucceſſively, and every time with proportionable caution. The laſt, whoſe teeth is like the fineſt needles, requires the utmoſt ſkill, and ſhould be truſted with few hands.

FLEA, *Pulex*, in zoology, a genus of inſects without wings, of a roundiſh, compreſſed figure: the legs are three pair, and formed for leaping; the eyes are two, and ſimple; the mouth is bent downwards: the colour is a deep purple, approaching to black.

FLEA-BITTEN, that colour of a horſe, which is white or grey, ſpotted all over with dark reddiſh ſpots. See HORSE.

FLEAM, in ſurgery and farriery, an inſtrument for letting a man or horſe blood.

FLEECE, the covering of wool, ſhorn off the bodies of ſheep. See WOOL.

Order of the Golden FLEECE, an order of knighthood inſtituted by Philip II. duke of Burgundy. Theſe knights were at firſt twenty-four, beſides the duke himſelf, who reſerved the nomination of ſix more; but Charles V. increaſed them to fifty. He gave the guardianſhip of this order to his ſon Philip, king of Spain, ſince which the Spaniſh monarchs are chiefs of this order. The knights had three different mantles ordained them; at the grand ſolemnity, the collar and fleece.

FLEET, in naval affairs, a company of ſhips of war, or merchantmen, or both, bound on any particular expedition or voyage.

As the ſecurity, wealth, and glory of theſe kingdoms principally depend on the reſolution and ſkill with which our fleets are conducted, it may be thought neceſſary to give our readers, who are unacquainted with this ſubject, a clearer idea of the operations of fleets and ſquadrons than they may have formed before; this we more chearfully attempt, as it ſeems to have been wholly neglected hitherto in works of this kind.

The principal article to be conſidered in a fleet at ſea is order, by which is meant the different methods of ranging or drawing it up in the ſeveral lines and forms for which it may be deſigned: in which two things are to be conſidered; firſt, the poſition of each ſhip with regard to the wind; ſecond, the poſition of each ſhip with reſpect to the fleet. We cannot make any alteration in either of the circumſtances without changing the whole poſition of the line, which will otherwiſe remain complete. See the article LINE.

When a fleet engages, it ought to be drawn up in a different form from that in which it ſails. A fleet that ſails in ſight of an enemy muſt alter its poſition from that it would maintain, were there none in view, or none to be expected. When a fleet ſails before the wind, it has likewiſe its particular form of ſailing, as it has alſo when it chaces an enemy, makes a retreat, guards a ſtreight or paſſage, or is obliged to force through one; or whether at anchor in a road or harbour, or going into either, to inſult or attack an enemy. In this variety of circumſtances proper regard muſt be had to the moſt advantageous poſition or form the fleet can be ranged in, before it enters upon action.

There are three things to be conſidered before we can judge of the good form or diſpoſition of a fleet. 1. If that form puts it into the beſt diſpoſition of executing the admiral's deſign; ſuch as the moſt expeditious as well as moſt commodious order of ſailing on any enterprize, &c. or if when obliged to retreat, ſuch arrangement ſecures it beſt from the attacks or purſuit of an enemy. 2. If that order cloſes the fleet more or leſs; becauſe the cloſer the ſhips are, they are the leſs liable to be ſeparated; the ſeveral commanders can better aid and aſſiſt each other upon any occaſion, and have the eaſier communication with their reſpective admirals and commanding officers. 3. If from this order the line of battle may be eaſieſt formed; becauſe all orders muſt tend principally to that, as the only one to engage to advantage. See EVOLUTION.

In a naval engagement, as we ſhall fully explain in that article, the ſhips are drawn up in a line of battle in two columns parallel to each other, cloſe upon a wind. See CLOSE-HAULED.

There are ſeveral advantages which reſult from being to windward, as 1. The fleet to windward can edge down on the enemy, when and as near as ſhall be judged convenient; conſequently regulates the time and diſtance moſt advantageous to come to action. 2. If the fleet to windward is more in number, it may eaſily detach ſome ſhips to ſend after the rear of the enemy, which muſt undoubtedly throw them into confuſion. 3. If any of the ſhips of the fleet to leeward ſhould be diſabled, whether in the van or rear, or even in the centre; the fleet to windward may with the greater eaſe ſend down their fire-ſhips upon them, or ſend a detachment after any part of the flying enemy. 4. We muſt alſo attribute amidſt other advantages of being to windward, that of being ſooner freed from the inconvenience of the ſmoke of the enemy, as well as of our own; for the wind repelling the ſmoke of the cannon back again into the ſhip, ſo greatly incommodes thoſe who are quartered at the guns as to deprive them totally for ſome time of the ſight of the enemy.

On the other hand the advantages of being to lee-ward are likewiſe conſiderable, inſomuch that there are who maintain they are at leaſt equal to thoſe of being to windward; but if all circumſtances are duly conſidered, they will certainly find the advantages of being to windward the greateſt a fleet can poſſibly have, whether ſuperior or inferior to the enemy; though we muſt allow that on ſome occaſions, as when the wind blows hard, it may be more adviſeable to get to leeward, if we can, eſpecially if the ſea runs ſo high that the weather, or windward fleet, cannot open its loweſt tier, when obliged to engage a greater number of ſhips, or in an action between two ſingle ſhips.

1. The fleet to leeward fire to windward, and conſequently the ſhips may make uſe of their lower tier of guns, without being under apprehenſion that any ſudden ſquall of wind ſhould over-power them by the water ruſhing in irreſiſtably between decks; an advantage which the Engliſh fleet, under ſir Edward Hawke, had in ſome meaſure over the French fleet, commanded by monſ. Conflans, in that memorable action off Belliſle, Nov. 20, 1759, where they fatally experienced our ſuperior ſkill, reſolution, and ſeamanſhip. This circumſtance is certainly the greateſt advantage a fleet to leeward can have; for it is difficult to conceive the confuſion and terror which ſudden guſts of wind occaſion amongſt the men between decks, when the waves pour in and lay the ſhip on her broadſide, ſo as often to endanger her overturning, or ſinking before the ports can be ſecured.

2. The fleet to leeward may eaſier cover any of their ſhips which are diſabled in action, which the fleet to windward cannot effect without great difficulty, and even the riſk of being deſtroyed in the attempt.

3. The fleet to leeward may more eaſily make a retreat if defeated, whereas the fleet to windward cannot ſo well eſcape, without being reduced to the neceſſity of forcing its way through the enemy's line, which muſt be attended with the moſt fatal conſequences.

When a fleet is obliged to retreat in ſight of an enemy, the beſt way to ſecure its retreat will be by ſailing in a ſort of half moon, the admiral being in the center, the fleet divided and ranged in order, one half on the ſtarboard, and the other half ſtretching out on the larboard ſide, and keeping the fireſhips, tranſports, &c. in the middle. This manner of ranging a fleet ſeems the moſt adviſeable, becauſe the enemy can never approach thoſe that endeavour to eſcape, without expoſing themſelves at the ſame time to the fire of the ſhips to windward. If the admiral thinks this form gives too great an extent to his fleet, he may eaſily cloſe his wings or quarters, and make the half-moon more complete; in the midſt of which he may place his convoy in ſafety.

The moſt natural courſe, however, in this form of ſailing, is to ſteer away before the wind: but if neceſſary, the ſhips may bear away large on either tack, or even may keep cloſe upon a wind.

In chacing a fleet that endeavours to eſcape, the beſt cruiſers are detached after them, in order to pick up the ſtragglers or force them to action: the body of the victorious fleet ſhould keep the ſame order or line with the enemy, as nigh as poſſible, to be ready for action if neceſſary. This however is only to be underſtood when the fleet that is chaced may not be ſo inferior to the other,

but that it may hazard an action; for if the one bears no proportion to the other, they muſt bear down upon them in the ſame manner as a conquering army aſhore carries all before it when it has forced an enemy's camp: otherwiſe, were the conquerors to wait drawing up in form, the enemy would undoubtedly take the advantage of ſuch an opportunity to make their eſcape.

In order to protect the entrance of a ſtreight or paſſage in the moſt effectual manner, there ſhould be a fleet nearly double in number to that which would force its way through; there muſt then be two diviſions made, the one to keep one ſide while the other is ranged along the other, that when the enemy preſents themſelves at the entrance, the weathermoſt ſquadron may crowd all the ſail it can before the wind upon them, at the ſame time that the leeward ſquadron keeps its wind to intercept them: ſo that in this manner it will be impoſſible for the enemy to eſcape by any manœuvre it may attempt. The eſſential point of the commanding officer who attempts to force a paſſage, is to avail himſelf of the reigning winds which may beſt favour his deſigns, and poſſibly it would be moſt expedient to range his ſquadron in the form of a retreat, by cloſing the wings or quarters a little, to give them the leſs extent; in this the ſquadron can never be attacked without being able to defend itſelf from all quarters to greater advantage than in the former poſition.

When a fleet comes to an anchor, there are five circumſtances to be conſidered: 1. That the ground be good and holding. 2. That the place be well ſheltered againſt the reigning winds which blow on that coaſt. 3. That the ſhips may eaſily get under ſail with the ſame wind that may ſerve an enemy, and at the ſame time be able to diſpute the advantage of the wind with them. 4. That they may readily form the line as ſoon as they get under ſail. 5. That the ſhips may have room to keep clear of each other in getting under way, in order to which they ſhould be regularly anchored in one or many lines, about three cables length aſunder, and one hundred and twenty fathoms between each ſhip.

When a fleet is under a neceſſity of continuing at ſea in bad weather, it ſhould form itſelf into three columns, leaving a great interval between each ſhip, without at the ſame time widening the diſtance between the columns; ſo that it may be in this manner leſs liable to be ſeparated, and the ſhips in leſs danger of falling aboard each other.

If the ſhips have a good offing and ſea-room enough to drive, they will lie to under their courſes; which will ſubject them to labour leſs, and not ſtrain ſo much on their maſts, rigging, &c. but if they ſhould not have drift enough, they muſt lie to under their main-ſails, or mizens only, which will ſtill keep them much eaſier than if they were under no ſail at all.

Laſtly, if a fleet deſigns to force into an harbour, wind, weather, &c. permitting, ſome ſhips ſhould be ordered to divert the out-forts, by coming to an anchor and placing themſelves in ſuch a manner as to bring their broadſides to bear upon them: when that is accompliſhed, the briſk and continued fire of a ſhip will greatly diſtreſs the enemy; but more eſpecially againſt ſtone-works, which fly about and do great execution, whilſt the main body of the fleet puſhes into harbour.

FLEETING, among ſailors, changing the ſituation of a tackle, when the blocks or pullies are drawn together: the uſe of fleeting is to ſeparate the powers which produce any great effort, that the force may be increaſed, which is deſtroyed by their meeting.

FLEMISH, or the FLEMISH-TONGUE, is that which we otherwiſe call Low Dutch, to diſtinguiſh it from the German, of which it is a corruption, and a kind of dialect. See GERMAN.

It differs from the Walloon, which is a corruption of the French language. The Flemiſh is uſed through all the provinces of the Netherlands.

FLEMISH BRICKS, a neat, ſtrong, yellow kind of bricks, brought from Flanders, and commonly uſed in paving yards, ſtables, &c. being preferable for ſuch purpoſes to the common bricks. See BRICK.

FLESH, *Caro*, in anatomy, a ſimilar fibrous part of an animal body, ſoft and bloody, being that of which moſt of the other parts are compoſed, and whereby they are connected together; or more properly, it is ſuch parts of the body where the blood-veſſels are ſo ſmall, as only to retain blood enough to preſerve their colour red.

FLESH, among botaniſts, is all the ſubſtance of any fruit that is between the outer rind and the ſtone; or that part of any root that is fit to be eaten.

FLESH-COLOUR. See CARNATION.

FLEUR DE LISE, in heraldry, the ſame with flory. See the article FLORY.

FLEXIBLE, in phyſics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

FLEXION, in anatomy, is applied to the motion by which the arm or any other member of the body is bent. It is alſo applied to the muſcles, nerves, &c.

FLEXOR, in anatomy, a name applied to ſeveral muſcles, which are ſo called from their office, which is to bend the part to which they belong, in oppoſition to the extenſors, which open or ſtretch them, as 1. Flexors of the head, which are the maſtoidæus, the rectus major anticus, and the rectus minor anticus. 2. Flexors of the neck, viz. the ſcalenus and longus. 3. Flexors of the back and loins, the quadratus lumborum, the pſoas parvus, the intertranſverſales lumborum. 4. Flexors of the cubitus, the brachiæus externus, and brachiæus internus. 5. Flexors of the carpus, the radiæus internus, the ulnaris internus, and the palmaris. 6. Flexors of the firſt, ſecond, and third phalanx of the fingers, viz. the four lumbricales, the ſublimis or perforatus, and the perforans or profundus. 7. Flexors of the thigh, called alſo elevators, the pſoas magnus, the iliacus, and the pectinæus, called alſo lividus. 8. Flexors of the tibia, the gracilis, the ſemimembranoſus, the ſeminervoſus, the biceps, and the poplitæus. 9. Flexors of the tarſus or foot, the tibialis anticus, and the peronæus anticus. 10. Flexors of the phalanges of the toes, the lumbricales, the perforatus, the perforans, and the flexor longus of the great toe, whoſe origin is in the poſterior part of the fibula, and its termination in the lower part of the laſt phalanx, together with the flexor brevis, the origin of which is from the middle os cuneiforme, and its termination at the two ſeſamoide bones of the great toe, which are joined by ligaments to its firſt phalanx. See the articles MASTOIDÆUS, RECTUS, SCALENUS BRACHIÆUS, &c. &c.

FLINT, *Silex*, in natural hiſtory, a ſemipellucid ſtone, compoſed of cryſtal debaſed with earth, of one uniform ſubſtance, and free from veins; but of different degrees of colour, according to the quantity of earth it contains, and naturally ſurrounded with a whitiſh cruſt.

Flint is a ſtone of an extremely fine, compact, and firm texture, and very various, both in ſize and figure. It is of all the degrees of grey, from nearly quite black to almoſt quite white. It breaks with a fine, even, gloſſy ſurface; and is moderately tranſparent, very hard, and capable of a fine poliſh. It readily ſtrikes fire with ſteel, and makes not the leaſt effervеſcence with aquafortis, and burns to a whiteneſs. Its uſes in glaſs-making, &c. are too well known to need a particular recital.

It is not uncommon to find on our ſhores fine, pellucid, flinty bodies, ſtreaked or veined with white, black, brown, &c. Theſe are the agates of this country, and anſwer in every particular, but fineneſs, to the gem. See the article AGAT.

The manner of preparing flints for the nicer operations in the glaſs-trade, is this: after freeing them from the white cruſts with which they are commonly ſurrounded, calcine them in a ſtrong fire; then powdering them in an iron mortar, ſift the powder through a very fine ſieve: pour upon this powder ſome weak aquafortis, to diſſolve any particles of iron it may have got from the mortar; then, after ſtanding ſome time, waſh it well with hot water, and dry it for uſe.

Oil of FLINTS, a name given to the liquor obtained from a mixture of four ounces of calcined and powdered flints, with twelve ounces of ſalt of tartar: this being melted together in a ſtrong fire, runs into glaſs; which is to be powdered and ſet in a cellar, where it runs into an oil per deliquium.

FLOAT *of a Fiſhing-Line*, the cork or quill that floats or ſwims above water. See the article FISHING.

FLOAT alſo ſignifies a certain quantity of timber bound together

together with rafters, athwart, and put into a river to be conveyed down the ſtream; and even ſometimes to carry burdens down a river.

FLOAT-BOARDS, thoſe boards fixed to water-wheels of under-ſhot mills, ſerving to receive the impulſe of the ſtream, whereby the wheel is carried round. See the article WHEEL and MILL.

It is no advantage to have too great a number of float-boards, becauſe, when they are all ſtruck by the water in the beſt manner that it can be brought to come againſt them, the ſum of all the impulſes will be but equal to the impulſe made againſt one float-board at right angles, by all the water coming out of the penſtock through the opening, ſo as to take place on the float-board. The beſt rule in this caſe is to have juſt ſo many, that each of them may come out of the water as ſoon as poſſible, after it has received and acted with its full impulſe. As to the length of the float-board, it may be regulated according to the breadth of the ſtream. See the article MILL.

FLOATAGES, all things floating on the top of the ſea or any water: a word much uſed in the commiſſions of water-bailiffs.

FLOATINGS, in huſbandry, the drowning or watering of meadows.

FLOATING *of Cheeſe*, among houſewives, ſeparating the whey from the curd. See CHEESE.

FLOOD, a deluge or inundation of waters. See the article DELUGE.

FLOOKING, among miners, a term uſed to expreſs a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its courſe by the croſſing of a vein of earth or ſtone, or ſome different metallic ſubſtance; as in which caſe the load is moved to one ſide, and this tranſient part of the land is called a flooking.

FLOOR, in architecture, the under ſide of a room, or that part we walk on.

Floors are of ſeveral ſorts, ſome of earth, ſome of brick, ſome of ſtone, and ſome of wood.

Earthen floors are commonly made of loam, and ſometimes, when they are deſigned to make malt on, of lime and brook-ſand, and gun-duſt, or anvil-duſt, from the forge.

The manner of making theſe floors for plain country inhabitants, is as follows.—Take two thirds of lime, and one of coal-aſhes well ſifted, with a ſmall quantity of loamy clay; mix the whole together, and temper it well with water, making it up into a heap: let it lie a week or ten days; then temper it well over again: after which heap it up for three or four days, and repeat the tempering very high, till it become ſmooth, yielding, tough and glewy. Then the ground being levelled, lay your floor therewith, about two and a half or three inches thick, making it ſmooth with a trowel: the hotter the ſeaſon is, the better; and when it is thoroughly dried, it will make the beſt floor for houſes, eſpecially for malt-houſes.

If any one would chooſe to have their floors look better, let them take lime made of rag-ſtones, well tempered with whites of eggs, covering the floor about a quarter or half an inch thick with it, before the under-flooring be too dry. If this is well done, and thoroughly dried, it will look, when rubbed with a little oil, as tranſparent as metal or glaſs.

For brick and ſtone floors, ſee the article PAVING.

Carpenters, by the word floor, underſtand as well the framed work of timber, as the boarding over it.

Concerning boarded floors, it is to be obſerved, that the carpenters never floor rooms with boards, till the carcaſe of the houſe is ſet up, and alſo is incloſed with walls, leſt the weather ſhould wrong the flooring; yet they generally rough-plane the boards for flooring, before they begin any thing elſe about the building, that they may ſet them by to ſeaſon; which is done by laying them flat upon three or four balks, each board about the breadth of a board aſunder, the whole length of the balks: then, by laying another lay of boards athwart the laſt, and ſo on till they have laid them all in this manner, by which means they lie hollow for the air to play between them.

The beſt way of placing the principal timbers in a floor, is not to lay them over doors or windows, nor too near chimnies: the boards ſhould all lie one way, which is generally the way that you have the beſt viſto.

FLOOR, in ſhip-building, the bottom of a ſhip, or all that part on each ſide of the keel, which approaches nearer to an horizontal than a perpendicular ſituation; whence it is common to ſay, a ſharp floor, a flat floor, a long floor, &c. whence

FLOOR-TIMBERS, are thoſe which are placed immediately acroſs the keel, upon which the bottom of the ſhip is framed, and the upper-parts of the timbers are conſtructed. See TIMBER.

FLORAL, in general, ſomething belonging to a flower. See FLOWER.

Thus floral leaves are thoſe found only near flowers.

FLORAL GAMES, in Roman antiquity, annual games inſtituted in honour of the goddeſs Flora, which began to be celebrated on the fourth of the calends of May, or the twenty-eighth of April, and were continued to the calends, or firſt of May.

The floralia, or floral games, were celebrated in the Campus Martius, being firſt proclaimed by ſound of trumpet; and during the celebration, the ædiles ſcattered all manner of pulſe among the people. It is alſo ſaid, that during the floralia, harlots danced naked, playing a thouſand laſcivious tricks. They were firſt inſtituted in the 513th year of Rome.

FLORID STYLE is that too much inriched with figures and flowers of rhetoric.

FLORIDA, in geography, a name firſt given by the Spaniards to all that part of North America which lies north of the gulph of Mexico. However, all that retains the name Florida, at preſent, is the Peninſula between the colony of Georgia and Cape Florida, viz. between 25° and 30° of north latitude, and between 81° and 85° weſt longitude.

FLORILEGE, *Florilegium*, a name the Latins have given to what the Greeks call ἀνθολογία, anthology. See the article ANTHOLOGION.

FLORIN, is ſometimes uſed for a coin, and ſometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is ſtruck. The gold florins are moſt of them of a very coarſe alloy, ſome of them not exceeding thirteen or fourteen carrats, and none of them ſeventeen and a half. As to ſilver florins, thoſe of Holland are worth about 1 s. 8 d. thoſe of Genoa were worth 8 ½ d. ſterling.

Florin, as a money of account, is uſed by the Italian, Dutch, and German merchants and bankers, but admits of different diviſions in different places: in Holland it is on the footing of the coin of that name, containing twenty ſtivers. At Frankfort and Nuremberg it is equivalent to 3 s. ſterling, and is divided into creutzers, and pfinnings. At Liege it is equivalent to 2 s. 3 d. At Straſbourg, to 1 s. 8 d. In Savoy, to 11 d. At Genoa, to 8 ¼ d. And at Geneva, to 6 ½ d. See the article COIN.

FLORINIANS, *Floriniani*, in church hiſtory, a ſect of heretics, of the ſecond century, ſo denominated from their leader Florinus, who made God the author of evil.

They are a ſpecies of the gnoſtics, but deny the judgment and reſurrection, and hold that our Saviour was not born of a virgin. They were alſo called borborites. See the article BORBORITES.

FLORIST, *Floriſta*, according to Linnæus, is an author, or botaniſt, who writes a treatiſe called Flora, comprehending only the plants and trees to be found growing naturally in any place. However, in the more common acceptation of the word, floriſt ſignifies a perſon well ſkilled in flowers, their kinds and cultivation. See the article FLOWER.

FLORY, FLOWRY, or FLEURY, in heraldry, a croſs that has the flowers at the end circumflex and turning down, differing from the potence, inaſmuch as the latter ſtretches out more like that which is called patee. See the article POTENCE and PATEE.

FLOS, or FLOWER, in botany. See the article FLOWER.

FLOS, in chemiſtry, the moſt ſubtile part of bodies ſeparated from the more groſs parts by ſublimation, in a dry form.

FLOSCULOUS, among botaniſts, an appellation given to compound flowers made up of a number of leſſer ones, all incloſed in the ſame common cup.

The plants with floſculous flowers make one of Tournefort's claſſes, called by Linnæus ſyngeneſia. See the articles BOTANY and SYNGENESIA.

FLOUNDER, the Engliſh name of a well known fiſh, called by ichthyologiſts the pleuronectes with the eyes in the right ſide, the lateral or ſide lines rough, and ſmall ſpines at the fins.

FLOUR, the meal of wheat-corn, finely ground and ſifted. See MEAL.

FLOWER, *Flos*, among botaniſts and gardeners, the moſt beautiful part of trees and plants, containing the organs or parts of fructification. See the article FRUCTIFICATION.

The parts of a flower are the ovary or piſtil, the corolla or flower-petals, the ſtamina or chives, the empalement or calyx, the perianthium, pericarpium, and fruit. See the articles PISTIL, COROLLA, STAMINA, &c.

According to the number of petals, or flower-leaves, flowers are called monopetalous or one-leaved, dipetalous or two-leaved, tripetalous or three leaved, &c. Flowers are again diſtinguiſhed into male, female, and hermaphrodite: the male flowers are thoſe containing ſtamina, without any piſtil or fruit, commonly called ſtamineous flowers. The female flowers are ſuch as contain the piſtil, which is ſucceeded with fruit; theſe are called fruitful or knitting flowers. The hermaphrodites are thoſe which contain the organs of both ſexes, viz. ſtamina and piſtils; and theſe are by far the moſt numerous.

From the different figures and diſpoſition of the flower-leaves of plants, Mr. Tournefort has eſtabliſhed a ſyſtem of botany; whereas that of Linnæus is chiefly founded on the number and diſpoſition of the ſtamina. See BOTANY.

Flowers were in great requeſt among the ancients: they adorned their temples, houſes, and even tombs with them; but their principal uſe ſeems to have been at entertainments, where the gueſts were always decked with flowers, and even the room ſtrewed with them.

Quincy tells us, that flowers, deſigned for medicinal uſe, ſhould be plucked when they are moderately blown, and on a clear day before noon: and that for conſerves, roſes muſt be taken in the bud.

For the method of preſerving ſpecimens of flowers, ſee the article HORTUS SICCUS.

Eternal FLOWER, the Engliſh name of the xeranthemum. See XERANTHEMUM.

Everlaſting FLOWER, the Engliſh name of the gnaphalium. See GNAPHALIUM.

FLOWER-FENCE, the Engliſh name of the poinciana. See POINCIANA.

FLOWER-DE-LUCE, the ſame with the iris. See the article IRIS.

Sultan-FLOWER, the ſame with the cyanus. See the article CYANUS.

Sun-FLOWER, the Engliſh name of the helianthus. See HELIANTHUS.

Trumpet-FLOWER, the ſame with the bignonia. See the article BIGNONIA.

Wind-FLOWER, the ſame with the anemone. See the article ANEMONE.

FLOWERS, in chemiſtry. See the article FLOS.

FLOWER-DE-LIS, or FLOWER-DE-LUCE, in heraldry, a bearing repreſenting the lilly, called the queen of flowers, and the true hieroglyphic of royal majeſty; but of late it is become more common, being borne in ſome coats one, in others three, in others five, and in ſome ſemee, or ſpread all over the eſcutcheon in great numbers.

The arms of France are, three flowers de lis or, in a field azure.

FLOWING SHEET, in the ſea-language; the ſheets are ropes faſtened to the lower corners of the ſails, and they are ſaid to be flowing when the wind is fair or large, as it is termed by ſeamen, as the ſheets are at this time not drawn ſo tight as when the ſhips are cloſe-hauled.

A ſhip is ſaid to have a flowing ſheet when the wind croſſes the line of her courſe at right-angles, that is to ſay, a ſhip ſteering north, with the wind at eaſt, has a flowing ſheet; for if ſhe were cloſe-hauled, ſhe would ſteer two points nearer the wind, viz. N. N. E. See the article CLOSE-HAULED.

FLOX, among dyers, ſignifies well cleaned wool, uſed to abſorb the colours of cochineal.

FLUENT, in fluxions, the flowing quantity, or that which is continually either increaſing, or decreaſing, whether line, ſurface, ſolid, &c. See FLUXION.

It is eaſy to find the fluxions, where the fluents are given; but, on the contrary, it is very difficult to find the fluents of given fluxions.

FLUID, in phyſiology, an appellation given to all bodies, whoſe particles eaſily yield to the leaſt partial preſſure, or force impreſſed.

Some philoſophers make the following diſtinction in fluids; thoſe which flow or ſpread themſelves till their ſurfaces become level or horizontal, they call liquid; in contradiſtinction to flame, ſmoke, vapour, &c. which are alſo fluids, but do not acquire ſuch a ſurface. Thoſe which are capable of exciting in us the idea of moiſtneſs, as water, &c. they call humid, diſtinguiſhing them thereby from air, quickſilver, and melted metals. But theſe diſtinctions are quite unneceſſary in a philoſophical ſenſe; the ſurfaces of all fluids being level, or horizontal, when not prevented by the bodies about them: and humidity is only a relative quality; for though quickſilver will not moiſten or ſtick to a man's finger, it will to ſilver or gold. See FLAME, SMOKE, LIQUID, &c.

The nature of a fluid, as diſtinguiſhed from that of a ſolid, or hard body, conſiſts in this, that its particles are ſo looſely connected together; that they readily move out of their places when preſſed with the leaſt force one way more than another. From whence philoſophers conclude, that theſe particles are exceedingly minute, ſmooth, and round, it being otherwiſe impoſſible they ſhould move with ſuch freedom upon the leaſt inequality of preſſure.

Thoſe particles conſidered ſeparately, are endued with all the common properties of matter, and are ſubject to the ſame laws of motion and gravitation with larger bodies. To enquire, therefore, into the nature of fluids, is to conſider what appearances a collection of very ſmall round bodies, ſubject to theſe laws, will exhibit under different circumſtances.

Laws and Properties of FLUIDS.—1. All fluids have little degree of compreſſibility, except air; or they cannot, by any force, be compreſſed into a much leſs ſpace than what they naturally poſſeſs, as is proved by the Florentine experiment, of filling a globe of gold with water, which, when preſſed with great force, cauſes the water to tranſude or iſſue through the pores of the gold, in form of a dew all over its ſurface. See WATER.

2. All fluids gravitate, or weigh in proportion to their quantity of matter, and that not only in the air, but *in proprio loco*: or, a fluid weighs the ſame, communicating with a quantity of that fluid, as *in vacuo*; which all philoſophers, till very lately, have denied.

The reaſon was this, becauſe philoſophers found that a bucket of water, in water, weighed nothing, that is, that becauſe there was no relative gravity in water, they very ſtrangely inferred there was no abſolute gravity in any part or particle of water, whilſt it remained in water, but only became heavy when taken out or ſeparated from the reſt. But their miſtake is eaſily evinced by the following experiment: let a bottle, or phial, with ſhot in it, to make it ſink in water when cloſe ſtopped, be hung at the end of a nice ballance, and then immerſed into a jar of water; while thus hanging in water, let it be counterpoiſed very exactly by weights put into the ſcale at the other end; then, pulling out the cork, the water will ruſh into the bottle, and deſtroy the equilibrium, by cauſing the ballance to deſcend; which will be a plain proof that water has weight in water.

That fluids gravitate, or are heavy, in the ſame manner with ſolids, is evident; becauſe the earth's attraction, which is the center of gravity, equally affects the particles of all ſorts of matter, and therefore excites the ſame endeavour, or tendency, towards the center of the earth, in the particles of a fluid, as in thoſe of a ſolid body; and this is what we call abſolute gravity. See GRAVITY.

Now ſince in fluids of the ſame kind as water, all the particles are reaſonably ſuppoſed equal and alike in all circumſtances,

cumſtances, they will be all equally affected by attraction, and therefore have, among themſelves, an equal tendency towards the earth's center; whence, ſince they gravitate equally, if they are equally obſtructed in their deſcent, as by the bottoms of the veſſels, &c. they will all retain the ſame poſition among themſelves, as if they were affected by no power at all; and thus they are ſaid to be relatively at reſt, or in a ſtate of quietus among themſelves; ſince no one particle of the ſame fluid has a greater ſhare of attracting power than another, no one will tend to deſcend before another; and therefore, among the particles of the ſame fluid, there is no ſuch thing as what we call relative or reſidual gravity, which is nothing but the exceſs of gravity, by which one body tends downwards more than another.

3. From the gravity of fluids ariſe their preſſure, which is always proportional thereto: and ſince we may ſuppoſe all the particles of a fluid to have equal bulk and weight, the gravity of the fluid, and conſequently the preſſure, will be always proportional to the altitude or depth thereof; whence the weight and preſſure of fluids on the bottoms of veſſels, &c. muſt be equal.

4. The preſſure of fluids upwards is equal to the preſſure downwards, at any given depth. To illuſtrate this and the foregoing propoſition, let ABCD (plate LXIII. *fig.* 8.) be a veſſel of water, whoſe altitude EF ſuppoſe to conſiſt of a column of 10 aqueous particles; then, it is evident, the firſt or uppermoſt particle 1 can affect the next particle 2, only by its weight and preſſure, which therefore is as 1; and ſince that particle 2 is immoveable, and action and re-action equal and contrary, the ſaid particle 2 will re-act upwards upon the particle 1, with a force which is as 1. In the ſame manner the particle 2 acts on the particle 3, by preſſure downwards, with two degrees of force, ariſing from its own weight and from that of the particle above it; and accordingly it is preſſed upwards with an equal force by the re-action of the particle 3. And ſo of all the reſt: wherefore the propoſitions are manifeſt.

5. The preſſure is upon all particles of the fluid, at the ſame depth, equal in every part; or the particles of a fluid, at the ſame depth, preſs each other, every way and in all directions, equally. For if any particle were preſſed more on one part than another, it muſt give way and yield, till the preſſure becomes every way equal; otherwiſe an inceſſant inteſtine motion of the particles muſt enſue, which is abſurd, and contrary to experience.

6. From the mutual preſſure and equal action of the particles, it follows, that the ſurface of a fluid muſt be perfectly ſmooth and even; for ſhould any part ſtand higher than the reſt, by any force, as attraction, &c. it would immediately ſubſide to a level with the other part, by the force of its own gravity, when that force is removed.

7. The figure of the ſurface of all fluids is ſpherical or convex; for all the particles equally gravitating towards the center of the earth, will take their places from it at equal diſtances at the ſurface, and ſo form a part of the ſuperficies of a ſphere, equal to the bulk of the earth.

Beſides the reaſon of the thing, we know from experiment, that the ſurface of large waters, as thoſe of the ſea or ocean, is convex; for a perſon ſtanding on the ſhore, and viewing a ſhip under ſail, directly before him, will loſe ſight thereof by degrees, the hull or body of the ſhip firſt diſappearing, then the lower parts of the maſt, then the top of the lower maſts, and laſtly, the top of the talleſt maſt. This is more fully explained in determining the figure of the earth. See the article EARTH.

8. Since fluids preſs equally every way, the preſſure of each particle againſt the ſide of a veſſel will be proportional to its altitude, and conſequently the preſſures of the particles 1, 2, 3, 4, &c. of a perpendicular column againſt the ſide BC (*fig.* 9.) will be a ſeries of numbers in arithmetical progreſſion, whoſe firſt term is 0; therefore the ſum of all the preſſures is equal to the number of preſſures multiplied by half the greateſt preſſure: but the number of preſſures is as the number of particles, or altitude of the fluid BC; alſo the greateſt preſſure is as the ſame altitude; wherefore the total preſſure againſt the ſide of a veſſel, is as the ſquare of the altitude of the fluid. See the article PROGRESSION.

This way of conſidering the quantity of lateral preſſure, by the arithmetical ſeries, is univerſal; whereas the common method reſtrains it to the property of an equicrural right-angled triangle, and to a veſſel of a cubical form, which we ſhall here give, for the ſake of proving it ſeveral ways: ſuppoſe ABCD (*fig.* 10.) a veſſel of a cubical form, that is, whoſe ſide BC is equal to the length of the bottom CD. If the diagonal BD be drawn, we ſhall have the lines 1 *a*=B 1, 2 *b*=B 2, 3 *c*=B 3, 4 *d*=B 4, &c. but B 1, B 2, B 3, B 4, &c. being as the altitudes of the fluid, will repreſent the lateral preſſures in the points, 1, 2, 3, 4, &c. therefore alſo the lines *a* 1, *b* 2, *c* 3, *d* 4, &c. will repreſent the ſame lateral preſſures; hence when the diſtances B 1, 12, 23, &c. are indefinitely ſmall, the lines *a* 1, *b* 2, *c* 3, *d* 4, &c. will be infinitely near each other; and ſo all thoſe lines drawn in the triangle BCD, will make the area of that triangle: therefore the ſum of all the lateral preſſure againſt the ſide BC, will be as the area of that triangle. But the area of the triangle BCD is as the ſquare of the ſide BC; conſequently, the ſum of all the lateral preſſures is as the ſquare of the altitude of the fluid BC.

9. Hence, if the veſſel AC (*fig.* 11.) be of a cubical form, the preſſure againſt a ſide BC, is half that upon the bottom CD, and conſequently the total preſſure againſt the ſides and bottom is equal to three times the weight of the fluid on the bottom of ſuch a veſſel.

10. The weight, preſſure, or effect of a fluid, upon the bottom DE (*fig.* 12.) of any veſſel ACDEF, is proportional to the altitude AE only, and not to the quantity of the fluid in the veſſel. For every column of particles GH, which preſſes downwards on the ſide of the veſſel EF, has its force deſtroyed by the equal reaction of the ſubjacent particle H in the ſide, and ſo cannot at all affect the bottom of the veſſel. Again, the preſſure of any column of particles LM upwards, againſt the ſide of any veſſel CD, is equally reached by the particle of the veſſel over it, and ſo its force or preſſure on the bottom muſt be the ſame as that of another column of particles AB of equal altitude with the fluid: whence the propoſition is evident.

11. Hence, a very ſmall quantity of fluid APRS may be made to counterbalance, or be equivalent to the weight or force of any given quantity TKGV, how great ſoever.

12. When any body is immerſed in a fluid, it loſes juſt ſo much of its weight as is equal to the weight of an equal bulk of the fluid; but the weight loſt by the body is gained by the fluid, which will be ſo much heavier than before.

This is the fundamental principle of every hydroſtatic proceſs, particularly of the whole doctrine of ſpecific gravities, which therefore cannot be made too plain and eaſy to be underſtood.

To this end, let ABCD (*fig.* 13.) be a veſſel filled with water, to the height EF; and let I be a cylindric body, heavier than water, to be immerſed therein, as at L. By this immerſion of the body I, a quantity of the fluid *abcd*, equal in bulk to the body, will be diſplaced by the ſuperior force, or greater gravity of the ſolid; and this quantity of fluid muſt aſcend, as being confined towards the bottom and ſides; and ſo riſe the ſurface of the liquor from EF to GH, and then will the quantity EFGH be equal to the bulk of the immerſed ſolid *abcd*. But as the ſolid comes to enter the fluid, each particle of the fluid, by its vis inertiæ, will reſiſt the ſolid, or endeavour to oppoſe its deſcent with all its power; and ſo the whole body of the fluid, that is removed or diſplaced by the ſolid, will reſiſt it by the united force of all the particles; but this force is equal to the gravity of the fluid removed, as is evident from hence, that the fluid ſo removed is obliged to aſcend or move in a direction quite contrary to gravity, wherefore the ſolid in its deſcent will be reſiſted by a force equal to the gravity of an equal bulk of the fluid.

And ſince the force which reſiſts the deſcent of ſolids is proportioned to their bulk only, it follows, that equal

bodies

bodies immerſed in fluids, loſe equal part of their weights; and therefore, a lighter body loſes more of its abſolute weight than a heavier one of the ſame bulk; and conſequently, if two bodies of an equal bulk are in equilibrio in the air, that equilibrium will be deſtroyed on their being immerſed in the fluid, becauſe that which has the largeſt bulk will loſe moſt weight in the fluid.

Again, it is plain, the weight of the fluid is augmented in the ſame proportion as that of the immerſed ſolid is diminiſhed; for the force or action of the fluid, on the bottom of the veſſel C D, is before immerſion to that afterwards, as the altitudes C F to C H; or to the bulks of the fluid E F C D, and G H C D. And ſince thoſe bulks act only by their gravity, it is plain the action of the fluid is increaſed only by the additional gravity of the quantities G H F E, which is equal to that which the ſolid loſes by immerſion. See GRAVITY.

13. If any body, E (*fig.* 14.) could be found without gravity it would, if placed on the ſurface A B, float thereon, without any part immerſed; for being devoid of gravity, it could have no force to diſplace any particles of the fluid, and ſink therein.

14 If an heavy body, F, lighter than an equal bulk of the fluid, be placed on its ſurface, it will ſink, or deſcend therein, till it has removed or diſplaced ſo much of the fluid whoſe weight is equal to that of the body. For there the preſſure upwards and downwards on the ſurface of the body is equal, and conſequently, the body will be there quieſcent, or in equilibrio with the fluid. Hence the whole ſolid is to the immerſed part as the ſpecific gravity of the fluid is to that of the ſolid. See the article HYDROSTATIC BALLANCE.

This caſe is not ſtrictly true, but in vacuo; for in the air ſuch a body may be conſidered as ſuſtained by two mediums, viz. air and water, in one of which it will ſink, or deſcend, and in the other, riſe.

15. If a ſolid, as G, equal in weight to an equal bulk of the fluid, be immerſed therein, it will take any ſituation indifferently on any part of the fluid, as at G, H, I, without any tendency to aſcend or deſcend therein; for being totally immerſed, it muſt remove a parcel of the fluid of equal bulk and weight, and conſequently the preſſure upwards is equal to the tendency downwards, on the lower ſurface every where; and therefore it can have no power to ſink. Alſo the preſſure downwards muſt be equal to the preſſure upwards, on the upper ſurface, whence it can have no tendency to riſe or ſwim; it will therefore remain at reſt in any poſition G, H, I, whereſoever in the fluid.

16. Laſtly, if a body K, or L, (*fig.* 15.) heavier than an equal bulk of the fluid, be immerſed therein, it will deſcend by the exceſs of its gravity above that of the fluid; for when immerſed, it will be reſiſted by the force of an equal bulk of the fluid, which therefore will deſtroy ſo much of the gravity of the ſolid; and conſequently the reſidue, or exceſs of gravity in the ſolid, is that alone by which it muſt deſcend.

The relative gravity of ſolids, by which they ſink or ſwim, is uſually illuſtrated by the deſcent and aſcent of glaſs images, and bubbles included in a jar of water, covered over with a bladder, ſo as to include a ſmall quantity of air between the bladder and water: the images, &c. have ſmall holes in the bottom of their feet through which ſome water is put into their bodies, and that in ſuch quantities as will render them but very little ſpecifically lighter than water; but ſome more ſo than others, that they may not begin to move altogether. See the repreſentation in *fig.* 16. The images being thus put to float in water, and the bladder tied down, if the hand be laid on the bladder, and gently compreſſes the air beneath, the air, by its ſpring, will act upon the water, and cauſe it to compreſs the air in the bodies of the images, by which means more water will be driven into their bodies; and when ſo much is got in as will make them ſpecifically heavier than the water, then they will begin to deſcend one after another; and by varying the degree of preſſure, you may keep them ſuſpended in any part of the fluid as you pleaſe.

From what has been premiſed of the nature of fluids, it will be eaſy to underſtand, that the lighteſt body P, (*fig.* 17.) may be depreſſed in the heavieſt fluid by any contrivance to keep the ſaid fluid from preſſing on the under ſurface of the light body, by which means only light bodies are made to ſwim. Thus cork, or wood, will abide at the bottom of a veſſel filled with quick-ſilver.

Again: on the other hand, the heavieſt body M may be made to ſwim in the lighteſt fluid, by keeping the ſaid fluid from preſſing on its upper ſurface, by means of the tube N O: for when by this means it is immerſed ſo deep as to keep off an equal weight of the fluid, the preſſure then of the fluid acting upon its under ſurface upwards, will be equal to the weight of the ſolid tending downwards; and therefore, if the ſolid be ſunk ever ſo little deeper, it muſt ſwim by the ſuperior force or preſſure of the fluid upwards.

Thus, for inſtance, if the body M be five times heavier than water of an equal bulk, and if by means of the tube N O, placed on its upper ſurface, the water be kept from preſſing thereon, that it be immerſed to ſeven times its thickneſs below the ſurface of the water, it is plain the preſſure on the under ſurface will be as ſeven, but downwards only as five; and therefore, ſince there is the exceſs of two degrees of preſſure upwards, it is plain the body cannot deſcend; but may very properly be ſaid to ſwim on the water: hence alſo the reaſon of trying the different gravity, denſity, or ſtrength of divers fluids, or ſpirituous liquors, by the hydrometer, or water-poiſe. See the article HYDROMETER.

Motion of FLUIDS. The motion of fluids, viz. their deſcent or riſe below or above the common ſurface or level of the ſource or fountain, is cauſed either, 1. by the natural gravity or preſſure of the fluid contained in the reſervoir, or fountain: or, 2. by the preſſure or weight of the air on the ſurface of the fluid in the reſervoir, when it is at the ſame time either taken off or diminiſhed on ſome part in aqueducts, or pipes of conduit. 3. By the ſpring, or elaſtic power of compreſſed or condenſed air, as in the common water engine. 4. By the force of piſtons, as in all kinds of forcing pumps, &c. 5. By the power of attraction, as in the caſe of tides, &c.

1. The moſt natural motion of fluids is that ariſing from the force of their own gravity, by which thoſe parts which ſtand higheſt preſs upon others below them, till by that means they riſe to the ſame horizontal level. Thus water in a fountain A B C D (*fig.* 18.) by its preſſure, raiſes that in the aqueduct F G H to the ſame height I K L M in every direction or poſition of the duct G H, or G N; unleſs the orifice of the ſaid duct be below that level, in which caſe the water will continually flow from the ſame. The reaſon hereof is evident from the principles already laid down, viz. that the preſſure of fluids was in proportion to the altitude only, and not according to the quantity thereof, and therefore the effect or riſe of the fluid in the duct muſt be equal thereto.

Hence we have conduits often ſupplied with water from ſprings, which lie above them; and cocks to ſupply the inhabitants of a town with water by pipes from a reſervoir, in a ſituation above the higheſt part of the town: hence alſo the deſcent of water in rivers, ſtreams, and canals from ſprings and ſources above the common ſurface of the earth; and the breaking out of ſprings at the bottoms and on the ſides of hills; from ciſterns and reſervoirs in the internal parts above them, which receive their water from rain, dew, condenſed vapour, melted ſnow, &c. diſtilling, or percolating through the pores or crevices and chaſms of the upper part of the earth. See the articles FOUNTAIN, SYPHON, CONDUIT, TANTALUS's CUP, JET D'EAU, RESERVOIRS, CANAL, SPRING, CISTERN, &c.

2. The ſecond cauſe of the riſe or motion of fluids is the preſſure of the air on the ſurface of that in the fountain or reſervoir: thus if a ſyphon or crane be immerſed with the ſhorter leg in water, and the air ſucked out of the inſtrument, the fluid will aſcend into the vacuous ſpace by the preſſure of the air on the water, and fill the whole cavity of the tube; and becauſe there is a greater column of water in the longeſt leg, it will preponderate and deſcend through it, and will keep flowing out till the veſſel is exhauſted to the orifice of the ſhorter leg. The effect of the common pump is from the ſame principle. See the article PUMP.

3. The third cauſe of the riſe and motion of fluids is by the

the ſpring or elaſtic power of condenſed air, upon which principle water-engines are contrived. See the article ENGINE.

4. The fourth cauſe is the force or preſſure of piſtons, upon which principle a variety of water-engines are conſtructed, as may be ſeen under the articles already referred to.

5. The laſt cauſe of the motion of fluids which we mentioned was that of attraction. We have elſewhere ſhewn how by this means any fluid will aſcend above the common ſurface in capillary tubes, &c. See the article CAPILLARY.

But the moſt notable and obvious motion of fluids ariſing from attraction, is that of the tides; the waters of the immenſe ocean, forgetful, as it were, of their natural quietus, move and roll in ſwelling tides obſequious to the ſovereign power of the moon, and weaker influence of the ſun. See the article TIDES.

Momenta and velocities of FLUIDS. The momenta of fluids, as well as of ſolids, is compounded of the quantity of matter and velocity; but in ſpouting fluids, the quantity of the fluid iſſuing through the ſame hole, in the ſame time, is always as the celerity of its motion, as is eaſy to conceive. Whence the momenta of ſpouting fluids, are proportional to the ſquares of the velocities, or quantities of matter iſſuing out in a given time. But ſince the momenta are the effect of preſſure, it is evident the velocity or quantity of ſpouting fluids is ever proportional to the ſquare root of the preſſure, or altitude of the fluid. From hence it appears, that the velocity of a fluid ſpouting at any depth below the ſurface is equal to the velocity a heavy body would acquire by falling from the ſame height; becauſe the velocity, as was obſerved, is always as the ſquare root of the ſpace deſcended through. If therefore on the altitude of the fluid A K, (*fig.* 19.) as a diameter, we deſcribe the ſemicircle A F K, and from any point therein, as I, we draw the perpendicular I H, that ſhall be proportional to the diſtance to which the fluid will ſpout from an adjutage at H: for the velocity will be, as the ſquare root of A H; and the time, as the ſquare root of H K; whence the product of theſe two will expreſs both the ſpace paſſed over by the projected body, and alſo the line H I.

Hence it follows, that a fluid will ſpout from a hole or adjutage D, in the center of the ſemicircle, or middle part of the altitude A K, to the greateſt horizontal diſtance K M poſſible; becauſe the perpendicular F D is the greateſt that can be drawn to the diameter A K. Alſo it is evident, that from two holes B and H, equally diſtant above and below the middle altitude D, the jets of water will be made to the ſame horizontal diſtance K N; becauſe the perpendiculars to theſe two points, viz. C and I H, are equal. Moreover, the horizontal diſtance K M, to which the water ſpouts from D the center, is equal to the diameter or altitude A K, or twice D F. For ſince the velocity of the jet at Q is equal to that acquired by falling through the height A D, or D K, it will, as being uniform, carry the fluid in an horizontal direction over twice the ſpace D K, or D F in the ſame time. And therefore, ſince the diſtances of jets from D and B are as D F to B C, and the diſtance of the jet from B will be alſo equal to twice B C, or K N = 2 B C. From what has been ſaid, it is eaſy to obſerve, that the motion of a ſpouting fluid is every way ſimilar to that of a projected ſolid. The path of the fluid is a parabola, becauſe it is impelled by two forces, one horizontal, the other of gravity in the perpendicular, in the ſame manner as in the projected ſolid. See PROJECTILE.

The impetus of the jets B, D, H, E, is as the height of the reſervoir A B, A D, A H, A E; the greateſt horizontal random K M, is that from the jet D, directed to the middle point F of the ſemi-circle; and any two jets equally diſtant as B, H, go to the ſame diſtance K N on the horizon. If the adjutage be horizontal, the jet will be a ſemiparabola; if oblique, it will be a whole parabola. See PARABOLA.

FLUOR, in phyſics, a fluid, or more properly, the ſtate of a body that was before hard or ſolid, but is now reduced by fuſion, or fire, into a ſtate of fluidity.

FLUOR, in mineralogy, implies a ſort of mineral concretion, frequently found amongſt ores and ſtones, in mines and quarries.

FLUOR ALBUS, or WHITES, in medicine, is a diſcharge of whitiſh gleety matter by the natural parts of the fair ſex. This humour iſſues ſometimes from the veſſels of the uterus, and ſometimes from the glands of the vagina. In the former caſe the diſcharge is ſuppreſſed during the time of the menſtrual courſes; in the latter, it ſubſiſts with them, and continues even in the time of pregnancy.

In both ſpecies of the diſeaſe, the principal intention ought to be directed towards mending the habit of body, from ſome fault in which they derive their origin: but when the ſeat of the diſtemper is in the vagina, it will, however, require topical applications.

Wherefore, generally ſpeaking, it will be proper to begin the cure by giving a vomit, eſpecially with ipecacuanha wine; frequent purging is indicated, chiefly with rhubarb; which may be taken either in ſubſtance, with the addition of aromatics, and in ſome caſes of a little calomel now and then; or in the tincture of rhubarb in wine. And the laxity of the fibres requires aſtringents, particularly ſuch as have ſteel in their compoſition.

As to external or topical remedies, which I have ſaid are neceſſary, when the vagina is the ſeat of the diſeaſe; we ought carefully to avoid applying all ſuch as are powerful repellers of the peccant humours: for thoſe only are ſerviceable which deterge and heal the little ulcers of that membrane. For my part, I have often with great ſucceſs, ordered the patient to inject a ſmall quantity of Bates's aqua aluminoſa, or of the camphorated vitriolic water, with a little Egyptian honey added to either, into the vagina through a proper ſyringe, at repeated times: and it will be of ſome ſervice to fumigate the vagina now and then with a powder made with equal parts of frankincenſe, maſtich, amber, and cinnabar of antimony, thrown on burning coals. *Mead's Monita Præcepta.*

FLUSH-DECK, or deck fluſh fore and aft, in ſhipbuilding, the upper-deck of a ſhip, which has no riſing at either end, only the common curve, or gradual aſcent from the middle towards the ſtem and ſtern, called by ſailors the ſheer.

FLUTE, *fiſtula*, an inſtrument of muſic, the ſimpleſt of all thoſe of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by ſtopping and opening the holes diſpoſed for that purpoſe along its ſide. The ancient fiſtulæ, or flutes, were made of reeds, afterwards of wood, and laſt of metal: but how they were blown, whether as our flutes, or as hautboys, does not appear.

German FLUTE, is an inſtrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is ſtopt with a tompion, or plug; and the lower lip is applied to a hole about two inches and a half, or three inches diſtant from the end. This inſtrument is uſually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, beſides that for the mouth, the loweſt of which is ſtopped and opened by the little finger's preſſing on a braſs, or ſometimes, a ſilver key, like thoſe in hautboys, baſſoons, &c. It is found exceeding ſweet and agreeable, and ſerves as a treble in a concert.

FLUTES or FLUTINGS, in architecture, perpendicular channels, or cavities, cut along the ſhaft of a column, or pilaſter. They are chiefly affected in the Ionic order, where they had their firſt riſe; though, indeed, they are uſed in all the richer orders, as the Corinthian and Compoſite; but ſeldom in the Doric, and ſcarce ever in the Tuſcan.

Each column has twenty-four flutes, and each flute is hollowed in exactly a quadrant of a circle; but the Doric has but twenty. Between the flutes are little ſpaces that ſeparate them, which Vitruvius calls ſtria, and we liſts: though, in the Doric, the flutes are frequently made to join to one another without any intermediate ſpace at all; the liſt being ſharpened off to a thin edge, which forms a part of each flute.

Sometimes the flutings are made flat, and are called facettes; but theſe have never ſuch a good effect as the others. Vitruvius ſays, that when there are flutings in

the column, there ought alſo to be eggs and anchors in the quarter-round of the capital, and even pearls and olives, in a baguette, to be made underneath, inſtead of annulets. Theſe eggs and olives ought to be in the ſame number with the flutings, and to be regularly diſtributed.

FLUX, in medicine, an extraordinary iſſue, or evacuation, of ſome humours of the body.

Flux of the urine. See Diabetes.

Flux, in hydrography. See Tide.

Flux, in metallurgy, whatever can cauſe any body, otherwiſe not at all, or hardly, fuſible by fire, to melt.

Fluxes, ſays Dr. Shaw, ſeem reducible to two general kinds, viz. the vitreous and the ſaline. By the vitreous we underſtand all thoſe which either have of themſelves, or readily aſſume, a glaſſy form in the fire; among the principal of which are reckoned the glaſs of lead, the glaſs of antimony, and borax. By the ſaline kind of fluxes are underſtood all thoſe that are compoſed of ſalts, whether tartar, nitre, fixed alcali, or the like. Among the principal of this kind we reckon the black flux, ſandiver, kelp, &c. See the articles Sandiver and Kelp.

The method of making the black flux is as follows. Take one part nitre, and two parts common tartar, and reducing each to powder, mix them together: deflagrate the whole in a crucible, by lighting the mixture a-top, which thus turns to a kind of alcaline coal, that is to be pulverized and kept cloſe in a glaſs, to prevent its diſſolving, as it would do in a moiſt air.

Some of the moſt powerful and cheap ſimple fluxes hitherto known, are dried wine-lees, dried cow-dung, and horſe-dung, dried river-mud, fuller's-earth, iron-filings, common ſalt, glaſs, kelp, or pot-aſhes, ſandiver, &c. which may be uſed in the larger work, as nitre, tartar, borax, ſal ammoniac, mercury ſublimate, &c. may in the ſmaller, or for the making of aſſays.

As for compound fluxes, they are numerous; almoſt every operator having his favourite flux. And, certainly, ſome fluxes are better adapted than others to certain ores. But perhaps a few general ones might be fixed upon, which ſhould ſerve inſtead of all thoſe hitherto commonly known and uſed, we will here recommend three, which are powerful, almoſt general, and not expenſive.

1. Take of nitre, prepared by long boiling it in lime-water; of ſea-ſalt, melted in the fire; ſandiver, and dry wine-lees, each one part; glaſs of lead, three parts; and powdered glaſs, eight parts; mix them all well together. This flux added in an equal weight, will fuſe a very ſtubborn ore.

2. For a ſtill ſtronger, take equal parts of white tartar, common ſalt and nitre, prepared as above: calcine them to a white powder; and mix therewith its own weight of glaſs and lead; and of this flux add two parts to one of the moſt ſtubborn ore.

3. For a powerful ſaline flux. Take of the ſtrongeſt ſoapboiler's lees, four pounds; white tartar, and common ſalt melted in the fire, each one pound: boil them together with five gallons of human urine, to a dry ſalt. This flux is particularly proper where ſulphur and cobalt abound, and render the ore very refractory.

But the great ſecret in making and adapting fluxes, is not only to ſeparate the metal already ripened in the ore, but even to mature and ripen the crude and immature part of the ore in the fire: ſomething of this kind, we apprehend, may be effected, as having reaſon to believe, that certain fluxes will obtain a larger yield of metal from certain ores, than other fluxes in common uſe, though eſteemed of the beſt, and though they are perhaps of the deareſt kind. Thus clean iron-filings will often do more than borax. But as the ſcales and crocus, or ruſt of iron, have been commonly uſed, inſtead of pure and perfect iron itſelf, for a flux, few operators appear acquainted with the excellence of perfect iron employed for this purpoſe. And many advantages are now obtained, by a prudent mixing of one ore with another of the ſame denomination, and with the ſlags or recrements of metals, in this way of flux.

The melting of gold and ſilver, and of their calxes, is greatly promoted by glaſs of lead, alkaline ſalts, &c. but when gold and ſilver, in the fuſion itſelf, are to be purged from other metals and ſemimetals, it is proper to uſe nitre only; or if not ſo, nitre always muſt be mixed with the other ſalts; for the ſemimetals and the four leſs perfect metals are deſtroyed by nitre.

In this operation, nitre, by its detonation with their ſulphurs, is in part alkaliſed, and, by the help of a gentle fire, turns their calxes into a vitreous, and much attenuated ſcoriæ.

From hence, the reaſon is plain why gold and ſilver, when made brittle, are readily reſtored to their malleability by nitre; for the ſame metals, and among the metals lead and tin moſt of all, communicate this fault to gold and ſilver: but theſe being changed, as before obſerved, by nitre, are then rejected by gold and ſilver in a ſimple fuſion, ſo that they can no longer mix with theſe metals, unleſs they are themſelves firſt again reduced to their metallic ſtate; and there is beſides theſe, no other body that can be mixed with ſilver and gold, to render them brittle, unleſs crude charcoal, happening to fall into the veſſel wherein theſe metals are melted, ſhould impregnate them with ſomething arſenical; there being ſome arſenic contained in coals of this kind, as has been demonſtrated by Stahl and Hoffman.

The leſs perfect metals, and ſemimetals, melt more eaſily by adding ſalts to them, than of themſelves: they always, however, loſe a great deal of their ſubſtance by this means; and this is is more particularly the caſe in regard to copper and iron. To amend this, it is neceſſary to add ſome kind of fat body, which prevents the deſtruction, and even reduces the metals already deſtroyed; and this is more neceſſary when the calxes, prepared either by burning, or by a detonation with nitre, are to be reduced.

A caution, very neceſſary to be obſerved, is, that all fluxes muſt be kept and uſed very dry, for moiſt ſalts foam very much; and when the operations are made in cloſe veſſels, if the fire is quickly increaſed, not being able to get rid of the moiſture, the veſſels will ſplit and break.

Fluxes being greatly attenuated, though confined in cloſe veſſels, part with their oily principle, and their alcaline ſalt remaining, begin to corrode and conſume the veſſels, of what matter ſoever they are made, and finally make their way through them, and get out. The firſt of theſe accidents is prevented by adding coal-duſt, which will never part with its oil without the help of a free air; and the others by an admixture of common glaſs, made of a due mixture of flints, and fixed alcali; for this is ſufficiently fuſible and melts with the fluxes; and by its viſcidity in ſome ſort coagulates and holds the ſalt of the flux together, and prevents it from eaſily corroding the veſſels.

FLUXIONS, in mathematics, are the velocities of the increments of variable or indeterminate quantities, conſidered not as actually generated, but as ariſing or beginning to be generated: and to form a juſt and adequate notion of them, we are to conſider mathematical quantities, not as made up of an infinite number of very ſmall conſtituent parts, but as generated or deſcribed by a continued uninterrupted motion or regular flux. A line is deſcribed, and in that deſcription is generated, not by the appoſition of parts, but by the continual motion of a point. A ſurface is generated by the uninterrupted motion of a line, moving in any direction except that of its length, and a ſolid by the conſtant motion of a ſuperfices, moving in any direction provided it be not in the plane of the ſaid ſuperfices. An angle by the rotation of one of its legs. And the quantities thus generated in equal ſpaces of time, become equal, greater or leſſer, according as the celerities of the motions, by which they were generated, are equal, greater, or leſſer.

For example, if the point A (plate LXIV. *fig.* 1.) move or be carried forward with an equal and uniform motion from A towards C, according to the direction of the line A C, and the point B move or be carried forward with an equal and uniform motion from B towards D, according to the direction of the line B D; and the velocity of the point A be equal to the velocity of the point B; the line A C, generated by the point A, will be equal to the line B D, generated by the point B in the ſame time.

Equation of Time.

5 JA 59

time. If the velocity of the point A be double to the velocity of the point B, the line AC will be double to the line BD, each generated in the ſame time; and if the velocity of the point A be triple of the velocity of the point B, the line AC deſcribed by the point A, in any ſpace of time, will be triple of the line BD, deſcribed by the point B in the ſame part of time; and univerſally if U repreſent the velocity of the point A, and *u* the velocity of the point B, the line deſcribed by the point A will be to the line deſcribed by the point B, in any time *t*, as U to *u*; and theſe velocities U and *u*, with which the generating or deſcribing points are carried, are called the fluxions of the lines AC and BD, as the lines AC and BD, thus deſcribed, are called the fluents.

Again, if the whole line AB (*fig.* 2.) be ſuppoſed to be carried along the line BD from B towards D, conſtantly perpendicular to BD, and parallel to itſelf; and at the ſame time the point A be imagined to move according to the direction of the line AB, it will by this compound motion, one according to the direction AC, and the other according to the direction AB, deſcribe either a right line, or a curve line, according as the velocities of it in each direction are adjuſted or proportioned to each other; as will the line AB, for the ſame reaſon, deſcribe a rectilineal or a curvilineal ſuperficies.

If the points A and B move with an equable and uniform velocity; that is, if, in time the point A with an equable velocity moves to P, the point B is carried with an uniform velocity to *b*, ſo that the ſpace AP, deſcribed in any given time by the point A, is to the ſpace deſcribed by the point B in the ſame time, as the whole ſpace AB deſcribed by the point A in a certain time, to the whole ſpace BD deſcribed by the point B, in the ſame time; the point A, by this compound motion, will deſcribe the right-line A*a*D, as will the whole line AB generate the parallelogrammic ſpace ABDC, while the ſame line AB, diminiſhing according to the velocity of the point A, deſcribes the triangular ſpace ABD.

For inaſmuch as in the ſame time that the line AB is ſuppoſed, with an uniform velocity, to have moved into the place A*b*, the point A is ſuppoſed to have moved with an equable velocity through the ſpace A*a* equal to AP, it is manifeſt that the point A will be found in *a*; and becauſe AP is, in every point P, to the whole line AB, as *a*P or AA is to the whole line BD or AC, the points *a a a* will be in a ſtraight line; and conſequently the point A, by the compound motion, will deſcribe the right-line A*a a a*D in the ſame time as the whole line AB ſhall have generated the parallelogram ABDC, and the ſame line AB, diminiſhing in the ratio of the velocity of the point A, ſhall have deſcribed the triangle ABD. But if in the time that the point B (*fig.* 3.) by the uniform motion of the line AB, moves over equal ſpaces B*b*, *bb*, &c. in equal times, the point A moves through ſpaces A*a*, A*a*, &c. equal to AP, AP, &c. which ſhall be to each other in a duplicate ratio of the ſpaces B*b*, B*b*, &c. run through by the point B in the ſame time, the point A will, by this compound motion, deſcribe the parabolic curve A*a a a*D, as will the whole line AB, the parallelogrammic ſpace ABDC, and the line *a b*, *a b*, the parabolic ſpace ABD*a*A.

For becauſe it is as $AB : AP :: BD^2 : P\rho^2$, whereſoever the point P be taken, the curve A*a a a*D will be a parabola. Or, if while the point B (*fig.* 4.) by the uniform motion of the line BA along the line DB, deſcribes equal ſpaces *Bb*, *bb*, *bb*, &c. in equal times, the point A deſcends through ſpaces AP, AP, AP, &c. which ſhall be to each other in a ſubduplicate ratio of the ſpaces B*b*, B*b*, B*b*, &c. the curve, deſcribed by this compound motion of the point A, will be a parabola convex towards AB, and the ſpace ABD is the ſupplemental part wherein the lines P*a*, P*a*, P*a*, which, in the former caſe, were the abſciſſa, now become the ordinates; and the lines AP, AP, AP, which before were equal to the ordinates, become now the abſciſſa. But if, inſtead of imagining the line AB to be carried along the line BD parallel to itſelf, we conceive the ſame line AB to revolve about the point B, fixed as a center, whilſt the point A moves in the direction AB, from A towards B, as before; then the point A, by theſe two motions, will deſcribe ſome one of the radial or ſpiral curves; and as all curves whatſoever ariſe from the different velocities of one or both of the points A and B, it will be eaſy from hence to conceive how any one, or all, of the infinite variety of curves may be generated.

From the generation of curves thus explained, the nature of fluxions will more evidently appear: For let A P *p* D (*fig.* 5.) repreſent any given curve, AB its axis, PM, *p m*, ordinates applied, and draw the lines P*b*, *p b*, parallel to the axis AB. Now inaſmuch as the points P and *b*, *p* and *b*, repreſent the ſeveral poſitions of the points A and B in the regular and orderly formation of the curve, ſo the lines P*b*, *p b*, which repreſent the ſeveral diſtances of theſe points aſunder at thoſe ſeveral moments of time, are very properly and ſignificantly called the ſeveral flowing values of the line AB; and as there is no imaginable moment of time wherein the points A and B are ſuppoſed to be at reſt, ſo there is no imaginable time wherein the line AB continues of the ſame length, but is conſtantly in a ſtate of change, and flowing into a new value; and, for the ſame reaſon, the ordinates PM, *p m*, &c. equal in length to the diſtances B*b*, B*b*, the ſpaces run through by the point B, being in a continual flux and change, are called the ſeveral flowing values of the baſe BD. In the generation or formation of any curve, if one of the points, B, for example, move with an equable and uniform motion, the other point A muſt neceſſarily move with an accelerated motion, according to ſuch degrees of acceleration as the nature of the curve required; for if the velocities of the generating points were equable, the path deſcribed would be a ſtraight line, and conſequently the velocity of the generating point A muſt be variable in every point of the curve. For as the motion of the point A towards B is a continued uninterrupted motion; ſo, being at the ſame time an accelerated one, the acceleration itſelf muſt be without the leaſt intermiſſion: and for the acceleration to be without intermiſſion is to undergo infinite and indeterminate variations. Again, if the unequal particles of the curve P*p* and *p*Q are generated in equal particles of time, there muſt be infinite variations of the velocity of the generating point A, between the points P and *p*, as alſo between the points *p* and Q; and as the point B may be conceived to move with an accelerated motion towards D, the velocity of the point B, in every conceivable part of the line BD, muſt be accelerated; and conſequently there muſt be the infinite variations of velocity between the points *p* and R, and Q and *r*, while thoſe increments *p*R, Q*r*, of the ordinates *p m*, QN, are generated.

Inaſmuch therefore as an infinite variety of velocities is requiſite to the production or formation of any increment or generated quantity, ſuch as P*p* or *p*R, &c. how ſmall ſoever, ſo in order to compare theſe increments together, it is abſolutely neceſſary to conſider them in their ariſing ſtate, or before they begin to be; and theſe velocities are accurately and exactly, in the firſt ratio of the increments, conſidered as ariſing. So that to find the fluxions of flowing or determinate quantities is to find the velocities with which they begin to be generated in the firſt moments of formation. And the ſame way of reaſoning obtains, whether we conſider the firſt or laſt ratio's of the velocities of the incremental parts; that is, whether we conſider them in their firſt ratio's, as ariſing, or whether we conſider them in their laſt ratio's, as vaniſhing and ceaſing to be.

From what has been ſaid, it is manifeſt, that the progreſſion of fluxions is without end, that is, that there are fluxions of fluxions, and fluxions of fluxions, &c. in infinitum.

Notation of FLUXIONS. — Conſtant, or determinate quantities, that is, ſuch as never increaſe or decreaſe, but perpetually remain the ſame, are uſually, for the ſake of diſtinction, and to avoid confuſion, denoted by the firſt letters of the alphabet, as *a*, *b*, *c*, *d*, &c.

Indeterminate or flowing quantities, that is, ſuch quantities as are formerly increaſing or decreaſing by a perpetual and regular flux of motion, are commonly expreſſed by the latter letters of the alphabet, ſuch as *u*, *x*, *y*, *z*; and their fluxions, or celerities of increaſe or decreaſe, by the ſame letters, with a dot over the head; thus, $\dot{u}$, $\dot{x}$, $\dot{y}$, $\dot{z}$, repreſent the fluxions of the quantities *u*, *x*, *y*, *z*: and, inaſmuch as theſe fluxions may be conſidered as fluents, and conſequently have their fluxions of celerity, and

and increaſe or decreaſe, theſe are uſually denoted by the ſame letters with two points or tittles over the head; thus, $\ddot{u}, \ddot{x}, \ddot{y}, \ddot{z}$, are the fluxions of u, x, y, z; and after the ſame manner, the fluxions of theſe, conſidered as fluents, are denoted by the ſame letters with three tittles, or points over the head; thus, $\dddot{u}, \dddot{x}, \dddot{y}, \dddot{z}$, and the fluxions of theſe with four points or tittles, thus, $\ddddot{u}, \ddddot{x}, \ddddot{y}, \ddddot{z}$, &c. and theſe are called firſt, ſecond, third, and fourth fluxions.

Thus, $\ddot{u}, \ddot{x}, \ddot{y}, \ddot{z}$, which are the firſt fluxions of $\dot{u}, \dot{x}, \dot{y}, \dot{z}$, are the ſecond fluxions of u, x, y, z, and $\dddot{u}, \dddot{x}, \dddot{y}, \dddot{z}$, which are the firſt fluxions of $\ddot{u}, \ddot{x}, \ddot{y}, \ddot{z}$, are the ſecond fluxions of $\dot{u}, \dot{x}, \dot{y}, \dot{z}$, and the third fluxions of u, x, y, z. In like manner $\ddddot{u}, \ddddot{x}, \ddddot{y}, \ddddot{z}$, are the firſt fluxions of $\dddot{u}, \dddot{x}, \dddot{y}, \dddot{z}$, the ſecond fluxions of $\ddot{u}, \ddot{x}, \ddot{y}, \ddot{z}$, the third fluxions of $\dot{u}, \dot{x}, \dot{y}, \dot{z}$, and fourth fluxions of u, x, y, z, &c.

And the fluxions of fractions, as well as their ſecond, third, fourth, &c. fluxions, are denoted by 1, 2, 3, or 4, &c. points placed horizontally in the break of the line that ſeparates the numerator from the denominator.

Thus, $\frac{a\dot{z}+z\dot{z}}{a-z}$, $\frac{a\ddot{z}+z\ddot{z}}{a-z}$, $\frac{a\dddot{z}+z\dddot{z}}{a-z}$ and $\frac{a\ddddot{z}+z\ddddot{z}}{a-z}$ are firſt, ſecond, third, and fourth fluxions of the quantity $\frac{az+zz}{a-z}$.

In like manner, if the quantity $az+zz$ be a root, or ſurd quantity, then its firſt, ſecond, third, and fourth, &c. fluxions are expreſſed by one, two, three, four, &c. points in the break of the vinculum.

Thus, $\sqrt[n]{\dot{a}z+z\dot{z}}$, $\sqrt[n]{\ddot{a}z+z\ddot{z}}$, $\sqrt[n]{\dddot{a}z+z\dddot{z}}$, $\sqrt[n]{\ddddot{a}z+z\ddddot{z}}$, denote the firſt, ſecond, third, and fourth fluxions of the quantity of $\sqrt[n]{az+zz}$, or $az+zz^{\frac{1}{n}}$: and after the ſame manner may the firſt, ſecond, third, fourth, &c. fluxions of any other quantity of the ſame kind be expreſſed.

The direct Method of FLUXIONS, or the flowing quantity being given to find its fluxion.—1. When the quantities are added. In the room of every quantity ſubſtitute its fluxion, and connect them with the ſigns of their reſpective quantities, and the ſum will be the fluxion required. Thus $\dot{x}$ is the fluxion of x, and $\dot{y}$ the fluxion of y; therefore, $\dot{x}+\dot{y}$ is the fluxion of $x+y$, and $\dot{x}-\dot{y}$ the fluxion of $x-y$; for if, while x increaſes, y diminiſhes, as the fluxion of x is poſitive, the fluxion of y muſt be negative; and for the ſame reaſon the fluxion $x-y+z$ will be $\dot{x}-\dot{y}+\dot{x}$, and the fluxion of $a+x+y+u$ will be $\dot{x}+\dot{y}+\dot{u}$; for a, being ſuppoſed, by the former way of notation, to be a conſtant quantity never increaſing nor diminiſhing, cannot undergo any alteration or change, and has therefore no fluxion, and conſequently vaniſhes in the operation. In like manner the fluxion of $x+a+y+b-u$ is $\dot{x}+\dot{y}-\dot{u}$; and after the ſame manner may the fluxion of any aggregate, whether ſum or difference, be found.

2. To find the fluxions of the product of any number of flowing quantities, multiplied into one another.

In order to this, let x and y repreſent the length and breadth of any right-angled parallelogram; then if y be ſuppoſed conſtant, the fluxion of the parallelogram will, from what has been already ſhewn, be $y\dot{x}$; and on the other hand, when y only flows, the fluxion of the parallelogram will be defined by $x\dot{y}$, conſtantly the total fluxion of the propoſed parallelogram, when both the length and breadth are in a flowing ſtate, will be truly expreſſed by $x\dot{y}+y\dot{x}$. Let it now be required to determine the fluxion of the product xyz; to do this, put $xy=u$, then will uz be equal to xyz, and the fluxion thereof equal to $u\dot{z}+z\dot{u}$, by what has been juſt now ſhewn; and alſo $x\dot{y}+y\dot{x}=\dot{u}$; hence, by ſubſtituting in $u\dot{z}+z\dot{u}$, the reſpective values of u and $\dot{u}$ in terms of x, y, z, and their fluxions, we ſhall at length have $u\dot{z}+z\dot{u}=xy\dot{z}+xz\dot{y}+yz\dot{x}$, for the required fluxion of the propoſed product xyz. Hence this general rule:

Multiply the fluxion of every particular flowing quantity by the product of the other quantities, and add the ſeveral products together, and the ſum will be the fluxion required.

3. To find the fluxions of quantities divided one by the other, or of fractions.

To inveſtigate a rule for this purpoſe; let $\frac{x}{y}$ be the fraction propoſed, and ſuppoſe $\frac{x}{y}=z$; then will $x=yz$; and conſequently $\dot{x}=y\dot{z}+z\dot{y}$; and $\dot{z}=\frac{\dot{x}-z\dot{y}}{y}$; for z ſubſtitute its value $\frac{x}{y}$, and we ſhall have $\dot{z}=\frac{\dot{x}-\frac{x}{y}\dot{y}}{y}$; $\frac{y\dot{x}-x\dot{y}}{y^2}$ for the fluxion of $\frac{x}{y}$. Hence this general rule.

Multiply the fluxion of the numerator by the denominator, and from the product ſubtract the fluxion of the denominator, multiplied into the numerator; then divide the remainder by the ſquare of the denominator, and the laſt quotient or fraction thence reſulting will be the fluxion of the quantity propoſed.

4. To find the fluxions of powers.

We have already ſhewn how to find the fluxion of the product of any number of flowing quantities; and therefore, if the quantities in any propoſed product be ſuppoſed equal among themſelves, a general rule for finding the fluxions of powers will from thence immediately emerge. Thus the fluxion of xy is $x\dot{y}+y\dot{x}$, and conſequently if $x=y$, then xy becomes xx, and $x\dot{y}+y\dot{x}$ becomes $2x\dot{x}$, for the fluxion of a ſquare xx. Again, the fluxion of xyz is $xy\dot{z}+xz\dot{y}+yz\dot{x}$; and when $x=y=z$, we have the fluxion of x^3 equal to $xx\dot{x}+xx\dot{x}+xx\dot{x}$, or $3x^2\dot{x}$. In the ſame manner the fluxion of x^4 will be found to be $4x^3\dot{x}$, and that of x^n, $nx^{n-1}\dot{x}$: whence this general rule for finding the fluxions of given powers.

Multiply the given power by its exponent; then leſſen the index of the power by unity; and laſtly, multiply the quantity thus produced by the fluxion of the root, and the laſt product will be the fluxion of the given power.

The inverſe Method of FLUXIONS, or having the fluxion given to find the flowing quantity or its fluent.

How from given fluxions to find the fluents, or flowing quantities themſelves, is a problem no leſs difficult than it is uſeful, and, in ſome caſes, almoſt impoſſible; and could it be completely and univerſally ſolved, it would, in a manner, render the ſcience of geometry complete, and ſet bounds to farther improvements.

Sir Iſaac Newton, the illuſtrious author of this diſcovery, tells us, in his Treatiſe of the Quadrature of Curves, that in order to find the fluents of given fluxions, we may aſſume a fluent at pleaſure; and that this aſſumption, which muſt be gathered from the conſideration of the nature of the fluxion itſelf, muſt be corrected, by putting the fluxion of the aſſumed fluent, equal to the fluxion propoſed, and comparing the homologous terms together: and after you have found the fluents of the given fluxions (if you doubt the truth of it), collect the fluxions of the fluents found, and compare them with the fluxions at firſt given; if they come out equal, the concluſion is right; if not, you muſt correct your fluents, ſo as to make their fluxions come out equal to the fluxion propoſed.

Now as the fluxions of flowing quantities are expreſſed by the ſame letters by which the fluents themſelves are with a tittle or point over them, ſo the fluents of the again are reſtored, by ſetting them down without it.

Thus, the fluent of the fluxion $b\dot{x}\pm c\dot{y}\pm d\dot{z}$, will b $bx\pm cy\pm dz\pm a$, where a denotes a conſtant quantity no determinate value, but taken at pleaſure.

For as a fluent may be either an expreſſion compoſed flowing quantities only, or may have, beſides, ſome co ſtant quantities, connected to it by the ſigns of + and − and as theſe conſtant quantities in bringing out the fluxi by the direct method, vaniſh and are loſt, their fluxio being equal to nothing; ſo it is neceſſary that the flu ſhould be expreſſed after ſuch a general manner, t it may repreſent indifferently any of all thoſe vari conſtant quantities, with which the flowing quanti themſelves might have been compounded, unleſs it known for certain that there are no ſuch quantities be connected, and then the fluent of the former flux will be ſimply $bx\pm cy\pm dz$; and in either caſe, if fluxions of theſe fluents be taken by the direct meth we ſhall have the fluxionary expreſſion firſt given, w ſhews that the aſſumptions are true.

Again, ſuppoſe it were required to find the fluent of this expreſſion $x\dot{y}+y\dot{x}$, aſſume it equal to $Axy \pm a$, where A repreſents any determinate quantity; then, by the direct method, the fluxion of $Axy \pm a$ will be $Ax\dot{y} \pm Ay\dot{x}$; and comparing this with the fluxion firſt given $x\dot{y} \pm y\dot{x}$, we ſhall find $A = 1$, whence xy is the fluent required.

Again, ſuppoſe the fluxionary expreſſion $xy\dot{z}+yz\dot{x}+zx\dot{y}$, were given, by aſſuming $Axyz \pm a$ for its fluent, and proceeding after the former manner, we ſhall find $A = 1$, whence xyz will be the fluent required; and hence ariſes this rule for finding the fluents of ſuch fluxionary products, where the fluxion of each particular flowing quantity is multiplied into the product of the reſt of the fluent quantities.

Rule.—Subſtitute, inſtead of each fluxion, its reſpective flowing quantity, and adding all the terms together, divide that ſum by the number of terms, and the quotient will give the fluent.

Hence the fluent $uxy\dot{z}+ux\dot{z}y+uyz\dot{x}+xyz\dot{u}$ will be found to be $uxyz$, by ſubſtituting u, x, y and z, in the room of $\dot{u}$, $\dot{x}$, $\dot{y}$ and $\dot{z}$ in the reſpective term, and dividing the ſum of the terms $uxyz+uxzy+uyzx+yzxu$, or $4xyuz$ by 4, the number of terms; and after the ſame way may the fluent of any ſuch fluxionary expreſſion be found.

Again, ſuppoſe the fluxionary quantity, whoſe fluent is required, were $nx^{n-1}\dot{x}$, aſſume Ax^n+a^n for the fluent required; then will its fluxion, by the direct method be $nAx^{n-1}\dot{x}$. Put this equal to the given fluxion, and we ſhall have $nAx^{n-1}\dot{x} = nx^{n-1}\dot{x}$; whence by comparing the homologous terms together, we ſhall find $A = 1$; whence the fluent will be $x^n \pm a^n$; and after the ſame manner the fluent of $mbz^{m-1}\dot{z}$ will be found to be $bz^m \pm a^m$, and by comparing theſe fluents with their reſpective fluxions, we may infer this general rule for finding the fluents of all fluxionary expreſſions that involve ſome power of the flowing quantity.

The rule.—Strike out the fluxionary letter, add unity to the exponent, and divide by the exponent ſo increaſed; the quotient is the fluent required.

Thus, if the fluxion $nx^{n-1}\dot{x}$ were propoſed, the fluent will be found to be x^n, by firſt rejecting the fluxionary letter; then adding unity to the exponent $n-1$, and dividing the whole by n, the exponent ſo increaſed.

And by comparing this, as well as the former methods, with the methods for finding the fluxions from given fluents, it will appear, that the fluents of ſimple fluxions, or ſuch as are not involved under a vinculum, are obtained by operations juſt the reverſe to theſe, whereby the fluxions are brought from their fluents; ſo that multiplication, depreſſing of powers of flowing quantities, and putting the fluxionary letters in the direct operation, are, in the inverſe operation, to be anſwered by diviſion, and that by the very ſame quantities as the multiplication was made, by the elevation of the flowing quantities, juſt as much as they are depreſſed, and by leaving out the ſame fluxionary letters as were in the former operations put in; and hence the fluent of $2x\dot{x}$ will be found to be x^2, of $4x^3\dot{x}$ to be x^4, of $x\dot{x}$, to be $\frac{xx}{2}$, of $x^3\dot{x}$ to be $\frac{x^4}{4}$ of $\frac{1}{2} \times x^{-\frac{1}{2}}\dot{x}$ to be $x^{\frac{1}{2}}$, of $\frac{3}{2} \times x^{\frac{1}{2}}\dot{x}$ to be $x^{\frac{3}{2}}$, of $\frac{5}{2} \times x^{\frac{3}{2}}\dot{x}$ to be $x^{\frac{5}{2}}$ of $\frac{x^2\dot{x}}{\sqrt{rx}}$, or $r \times x^{-\frac{1}{2}} \times x^2\dot{x}$, or $r^{-\frac{1}{2}} \times x^{\frac{3}{2}} \times \dot{x}$ to be $\frac{2}{5} \times r^{-\frac{1}{2}} + x^{\frac{5}{2}}$, or $\frac{2\sqrt{x^5}}{5\sqrt{r}}$.

And the ſame rules will hold good in finding the fluents of expreſſions, however compounded, where the terms conſiſt of certain powers of the flowing quantities multiplied into their reſpective fluxions.

Again, if the fluxional expreſſion be affected with a vinculum, that is, if there be ſome compound ſurd quantity multiplied into a fluxion, yet, if the fluxion ſtanding before the radical ſign, be the fluxion of the quantity contained under the radical ſign, the fluent, in this caſe, may be found by the general rules for powers already given. Thus, for example, if the fluxion propoſed be $\sqrt{ax-aa} \times a\dot{x}$, or $a\dot{x} \times \overline{ax-aa}^{\frac{1}{2}}$, becauſe the fluxion $a\dot{x}$, ſtanding before the radical ſign, is the fluxion of $ax-aa$, the quantity ſtanding under it, we muſt raiſe the quantity $\overline{ax-aa}^{\frac{1}{2}}$ to $\overline{ax-aa}^{\frac{1}{2}+1}$ or $\overline{ax-aa}^{\frac{3}{2}}$, and divide the quantity $\overline{ax-aa}^{\frac{3}{2}}$, thus elevated, by $\frac{3}{2}$, the index thus increaſed, and the quotient $\frac{2}{3}\overline{ax-aa}^{\frac{3}{2}}$, or $\frac{2ax-2aa}{3} \times \overline{ax-aa}^{\frac{1}{2}}$, or $\frac{2}{3} \times \overline{ax-aa} \times \sqrt{ax-aa}$, will be its fluent, or by putting z in the room of $\overline{ax-aa}^{\frac{1}{2}}$, the ſaid part of the fluxionary quantity given, we ſhall have $ax-aa = zz$, and $a\dot{x} = 2z\dot{z}$; whence $a\dot{x} \times \overline{ax-aa}^{\frac{1}{2}} = 2z^2\dot{z}$, and conſequently $\frac{2}{3}\overline{ax-aa}^{\frac{3}{2}}$, or $\frac{2}{3}\overline{ax-aa} \times \overline{ax-aa}^{\frac{1}{2}} = \frac{2}{3}z^3$ for the fluent of the given fluxion, the ſame as was before determined.

And although the fluxionary expreſſions, without the vinculum, be not the fluxions of the quantity contained under the vinculum, yet, if it has a conſtant ratio to it, the fluent may, notwithſtanding, be had in finite terms.

Thus, if the fluxionary quantity $x\dot{x} \times \overline{xx+aa}^{\frac{1}{2}}$ were given, were $x\dot{x}$ the fluxion without the vinculum, is to the quantity contained under the vinculum, as 1 to 2. If we put $\overline{xx+aa}^{\frac{1}{2}} = z$, we ſhall have $zz = xx+aa$, and by the direct method $2z\dot{z} = 2x\dot{x}$; whence $z\dot{z} = x\dot{x}$, and $z^2\dot{z} = x\dot{x} \times \overline{xx-aa}^{\frac{1}{2}}$, and conſequently $\frac{1}{3}z^3$, the flowing value of $z^2\dot{z}$, will be equal (by ſubſtituting $xx+aa$ in the room of zz, and $\overline{xx+aa}^{\frac{1}{2}}$, in the room of z) to $\frac{1}{3}\overline{xx+aa} \times \overline{x^2+a^2}^{\frac{1}{2}}$, the fluent of the given fluxion.

But if the fluxion without the vinculum be neither the fluxion of the quantity contained under it, nor bears any conſtant ratio to it; yet, notwithſtanding, in many forms of expreſſions the fluent may be had in finite terms.

Thus, if the fluxion $x^m \times \overline{a+x}^{\frac{1}{n}}$ were the expreſſions propoſed, if the exponent m be an integer, the fluent of the expreſſion may be had in finite terms.

And in all other caſes, when the flowing part of the quantity under the vinculum is raiſed to ſome power, and the fluxional expreſſion without the vinculum is only the fluxion of the root; in ſuch caſes the fluent itſelf cannot be had without having recourſe to an infinite ſeries.

After the ſame manner may the fluents of other fluxionary expreſſions of the ſame kind be found, by help of the general fluent.

The rules hitherto delivered for finding the fluents from firſt fluxions, will hold good in finding the fluents of ſecond, third, and fourth fluxions, &c. which likewiſe may be augmented or diminiſhed (and for the ſame reaſons as the fluents of the firſt fluxions were, by quantities that have no ſecond, third, fourth, &c. fluxions); and the ſame laws will obtain in all the ſuperior orders of quantities.

Several other methods might be ſhewn, for finding of fluents from given fluxions; but theſe that are exhibited are general, and properly adapted for the purpoſe.

FLY, in zoology, a large order of inſects, the diſtinguiſhing characteriſtic of which is, that their wings are tranſparent; by this they are diſtinguiſhed from beetles, butterflies, and graſshoppers. See the articles BEETLE, BUTTERFLY, &c.

FLY, in mechanics, a croſs with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a windlas, jack, or the like; by means of which the force of the power, whatever it be, is not only preſerved, but equally diſtributed in all parts of the revolution of the machine.

The fly may be applied to ſeveral ſorts of engines, whether moved by men, horſes, wind, or water, or any other animate or inanimate power; and is of great uſe in thoſe parts of an engine which have a quick circular motion, and where the power of reſiſtance act unequally in the different parts of a revolution. This has made ſome people imagine that the fly adds a new power; but though it may be truly ſaid to facilitate the motion, by making it more uniform, yet upon the whole it cauſes a loſs of power, and not an increaſe: for as the fly has no motion

of its own, it certainly requires a conſtant force to keep it in motion; not to mention the friction of the pivots of the axis, and the reſiſtance of the air. The reaſon, therefore, why the fly becomes uſeful in many engines, is not that it adds a new force to them, but becauſe, in caſes where the power acts unequally, it ſerves as a moderator to make the motion of revolution almoſt every where equal: for as the fly has accumulated in itſelf a great degree of power, which it equally and gradually exerts, and as equally and gradually receives, it makes the motion in all parts of the revolution pretty nearly equal and uniform. The conſequence of this is, that the engine becomes more eaſy and convenient to be acted and moved by the impelling force; and this is the only benefit obtained by the fly.

The beſt form for a fly is that of a heavy wheel or circle, of a fit ſize, as this will not only meet with leſs reſiſtance from the air, but being continuous, and the weight every where equally diſtributed through the perimeter of the wheel, the motion will be more eaſy, uniform, and regular. In this form, the fly is moſt aptly applied to the perpendicular drill, which it likewiſe ſerves to keep upright by its centrifugal force; alſo to a windlas or common winch, where the motion is quick; for in pulling upwards from the lower part, a perſon can exercife more power than in thruſting forward in the upper quarter; where, of courſe, part of his force would be loſt, were it not accumulated and conſerved in the equable motion of the fly. Hence, by this means, a man may work all day in drawing up a weight of forty pounds, whereas thirty pounds would create him more labour in a day without the fly.

FLY-BOAT, or FLIGHT, in the Dutch marine, certain merchant-ſhips of a very clumſy, uncouth built, nearly ſimilar to the genius of the builders: they are generally from four to ſix hundred tons, and diſtinguiſhed by a very high ſtern, like a Gothic turret above, and very broad buttocks below. See BUTTOCK.

FLYERS, in architecture, ſuch ſtairs as go ſtraight, and do not wind round; nor have the ſteps made tapering, but the fore and back part of each ſtair, and the ends, reſpectively parallel to one another; ſo that if one flight do not carry you to your intended height, there is a broad half ſpace, from whence you begin to fly again, with ſteps every where of the ſame length and breadth as before.

FLYING, the progreſſive motion of a bird, or other winged animal, in the liquid air. The parts of birds chiefly concerned in flying, are the wings, by which they are ſuſtained or waſted along. The tail, meſſrs. Willughby, Ray, and many others, imagine to be principally employed in ſteering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the leaſt uſe of it, which is chiefly to aſſiſt the bird in its aſcent and deſcent in the air; and to obviate the vacillations of the body and wings; for as to turning to this or that ſide, it is performed by the wings, and inclinations of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a veſſel. Birds do not vibrate their wings towards the tail, as oars are ſtruck towards the ſtern, but waft them downwards: nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is diſpoſed horizontally, and preſerves the ſame ſituation what way ſoever the bird turns.

In effect, as a veſſel is turned about on its center of gravity to the right, by a briſk application of the oars to the left, ſo a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons, changing their courſe to the left, would labour it with their right wing, keeping the other almoſt at reſt. Birds of a long neck alter their courſe by the inclinations of their head and neck, which altering the courſe of gravity, the bird will proceed in a new direction.

Artificial FLYING, that attempted by men, by the aſſiſtance of mechanics.

The art of flying has been attempted by ſeveral perſons in all ages. The Leucadians, out of ſuperſtition, are reported to have had a cuſtom of precipitating a man from a high cliff into the ſea, firſt fixing feathers, variouſly expanded, round his body, in order to break his fall. Friar Bacon, who lived five hundred years ago, not only affirms the art of flying poſſible, but aſſures us, that he himſelf knew how to make an engine wherein a man ſitting might be able to convey himſelf through the air, like a bird; and further adds, that there was then one who had tried it with ſucceſs; but this method, which conſiſted of a couple of large, thin, hollow copper globes, exhauſted of the air, and ſuſtaining a perſon who ſat thereon, Dr. Hook ſhews to be impracticable. The philoſophers of king Charles the Second's reign, were mightily buſied about this art. The famous biſhop Wilkins was ſo confident of ſucceſs in it, that he ſays, he does not queſtion but, in future ages, it will be as uſual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING-ARMY, a ſmall body under a lieutenant or major general, ſent to harraſs the country, intercept convoys, prevent the enemy's incurſions, cover its own garriſons, and keep the enemy in continual alarm.

FLYING-BRIDGE. See the article BRIDGE.

FLYING-CAMP. See the article CAMP.

FLYING-FISH, a name given by the Engliſh writers to ſeveral ſpecies of fiſh, which, by means of their long fins, have a method of keeping themſelves out of the water a long time.

FLYING-PINION is part of a clock, having a fly, or fan, whereby to gather air, and ſo bridle the rapidity of the clock's motion, when the weight deſcends in the ſtriking part. See the article CLOCK.

FOAL, or COLT, the young of the horſe kind. The word colt, among the dealers, is underſtood of the male kind.

Foals are uſually foaled about the beginning of ſummer, and it is the cuſtom to let them run till Michaelmas with the mare, at which time they are to be weaned. Some however are of opinion, that a foal is rendered much ſooner fit for ſervice by being allowed to ſuck the whole winter, and weaned about Candlemas or Shrovetide. When firſt weaned, they muſt be kept in a convenient houſe, with a low rack and manger for hay and oats; the hay muſt be very ſweet and fine, eſpecially at firſt, and a little wheat bran ſhould be mixed with their oats, in order to keep their bodies open, and make them eat and drink freely.

When foals are kept up in the winter, they are not continually to be immured in the ſtable; but in the middle of the day, when the ſun ſhines warm, they ſhould always be allowed to play about for an hour or two, and when the winter is ſpent, they ſhould be turned into ſome dry ground where the graſs is ſweet and ſhort, and where there is good water, that they may drink at pleaſure. The winter after this, they may be kept in the ſtable without any further care than that which is taken of other horſes; but after the firſt year, the mare foals and horſe foals are not to be kept together.

There is no difficulty to know the ſhape a foal is like to be of; for the ſame ſhape he carries at a month, he will carry at ſix years old, if he be not abuſed in after keeping. As for his heighth, it is obſerved that a large ſhin bone, long from the knee to the paſtern, ſhews a tall horſe; for which another way is to ſee what ſpace he has between his knee and his withers, which being doubled, it will be his height when he is a full aged horſe. There are alſo means of knowing their goodneſs; for if they are of ſtirring ſpirits, free from frights, wanton of diſpoſition, and very active in leaping and running, and ſtriving for maſtery, they prove generally good mettled horſes. It is a good mark alſo if their hoofs be ſtrong, deep, tough, ſmooth, upright ſtanding, and hollow. For the manner of breaking them, ſee the article HORSE.

FOCUS, in geometry and conic ſections, is applied to certain points in the parabola, wherein the rays reflected from all parts of theſe curves meet and concur.

The word is Latin, and literally ſignifies a fire-hearth.

FOCI *of an Ellipſis*, are two points as F *f* (plate LXIV. *fig.* 6.) in the longeſt axis of the ellipſis; from each of which, if any two right-lines are drawn, meeting each other in the periphery of the ellipſis, as *f* N, F N, or *f* L, F L, their ſum will be always equal to the longeſt axis; and therefore, when an ellipſis and its two principal axis are

are given, and the foci are required, you need only take half of the longeſt, or tranſverſe axis, in your compaſſes, and ſetting one foot in the point where the ſhorteſt, or conjugate diameter, cuts the periphery, and the other foot will cut the longeſt axis in the foci required. See ELLIPSIS.

FOCUS *of an Hyperbola* is that point in the axis through which the latus rectum paſſes. See CONIC *Sections* and HYPERBOLA.

FOCUS *of a Parabola* is that point in the axis wherein the ſemi-ordinate is equal to the ſemi-parameter; or it is that point through which the latus rectum paſſes. See CONIC *Sections* and PARABOLA.

FOCUS, in optics, is the point wherein the rays are collected, after they have undergone refraction. See MIRROR and LENS.

It is ſo called becauſe the ſun's rays being united within a very ſmall compaſs or circle, are greatly conſtipated and condenſed; by which means their action or heat is proportionally increaſed, and therefore objects poſited in that point will be greatly heated, burnt, or melted.

Virtual FOCUS, in dioptrics, is the point from which refracted rays, when they are rendered divergent by refraction, begin to diverge.

FODDER, any kind of meat for horſes, or other cattle. In ſome places, hay and ſtraw, mingled together, is peculiarly denominated fodder.

FODDER, in the civil law, is uſed for a prerogative that the prince has, to be provided of corn and other meats for his horſes, by the ſubjects, in his warlike expeditions.

FODDER, in mining, a meaſure containing twenty-two hundred and an half weight, though in London but twenty hundred weight.

FODINA, in anatomy, the labyrinth of the ear. See EAR.

FOECUNDITY, or FECUNDITY, the ſame with fertility. See the article FERTILITY.

FOENICULUM, *Fennel*, in botany, an umbelliferous plant, with dark green leaves divided into long capillary ſegments: the umbels are ſomewhat concave, and have no leaves or cup at their origin: the ſeeds oval, flatted on one ſide, and naked with prominent ſtriæ on the other: the root oblong, ſtraight, white, and about the thickneſs of the finger.

FOENICULUM DULCE, ſweet fennel, with whitiſh or pale greeniſh yellow ſeeds, generally crooked. It is annual, a native of the warmer climates, and cultivated in our gardens. The ſhops are commonly ſupplied, from Germany, with ſeeds, ſuperior to thoſe of our own growth.

Sweet fennel ſeeds are an uſeful ſtomachic and carminative, of an agreeable aromatic ſmell, and a moderately warm ſweetiſh taſte. They are ſometimes given in powder, from a ſcruple to a dram; and ſometimes candied.

FOENICULUM VULGARE, common fennel, or finckle, with ſmaller dark coloured, almoſt blackiſh, ſeeds. It is perennial, a native of ſome of the ſouthern parts of Europe, and cultivated in our gardens.

The ſeeds of this ſpecies are warmer and more pungent, but leſs ſweet, and of a leſs grateful flavour than thoſe of the preceding; and the ſame difference obtains in the diſtilled waters, diſtilled oils, and the ſpirituous extracts of the two kinds.

The roots, taken up early in the ſpring, have a pleaſant ſweetiſh taſte, with a ſlight aromatic warmth; but nothing of the peculiar ſtrong flavour of the leaves and ſeeds. They are ranked among the aperient roots, and ſuppoſed by ſome to be equivalent in virtue to the celebrated ginſeng of the Chineſe, from which however they differ conſiderably in their ſenſible qualities. See GINSENG.

FOENUGREEK, *Fœnum Græcum*, in botany, a plant with oblong or roundiſh leaves, ſet three on a pedicle; and whitiſh papilionaceous flowers, which are followed by long crooked flattiſh pods, containing yellowiſh rhomboidal ſeeds furrowed from angle to angle. It is ſown annually in the ſouthern parts of Europe, from whence the ſeeds are brought to us.

The principal uſe of theſe ſeeds is in cataplaſms and fomentations, for ſoftening, maturating, and diſcuſſing tumours; and in emollient and carminative clyſters.

FOETOR, in medicine, ſtinking or fœtid effluvia, ariſing from the body, or any part thereof.

FOETUS, in phyſiology, denotes the child while it is contained in the mother's womb, but particularly after it is formed, till which time it is more properly called embryo. See the article GENERATION.

Formation of a FOETUS. The formation of the bones in a fœtus, is very gradually and regularly performed. In the firſt two months, there is nothing of a bony nature in the whole. After this, the hardneſs of the parts, where the principal bones are to be ſituated, becomes, by degrees, perceptible. Dr. Kerkring deſcribes the progreſs of the oſſification from ſkeletons, which he had prepared from fœtuſes of two months, and thence up to nine. In the firſt two months, or to the end of that time, there appears not any thing bony. After this, in the third and fourth months, the ſeveral parts, one after another, acquire their bony nature. In the firſt ſtages, every thing is membranous, where the bones are to be: theſe, by degrees tranſmigrate into cartilages; and from theſe, by the ſame ſort of change continued, the bones themſelves are by degrees formed. All this is done by nature, by ſuch ſlow though ſuch certain progreſſions, that the niceſt eye can never ſee it doing, though it eaſily ſees it when done.

Fœtuſes increaſe proportionably leſs, the longer they continue in the womb. Mauriceau pretends, that the increaſe of a fœtus is ſixty-four times its own weight in triple the time. Thus, he ſays, that, at the birth, a child weighs twelve pounds, of ſixteen ounces each; at the three months, it weighs three ounces; at one month, $\frac{3}{8}$ of a drachm; and at ten days leſs than half a grain.

FOG, or MIST, a meteor, conſiſting of groſs vapours, floating near the ſurface of the earth.

Miſts, according to lord Bacon, are imperfect condenſations of the air, conſiſting of a large proportion of the air, and a ſmall one of the aqueous vapour; and theſe happen in the winter, about the change of the weather, from froſt to thaw, or from thaw to froſt: but in the ſummer and the ſpring, from the expanſion of the dew.

If the vapours, which are raiſed plentifully from the earth and waters, either by the ſolar or ſubterraneous heat, do, at their firſt entrance into the atmoſphere, meet with cold enough to condenſe them to a conſiderable degree, their ſpecific gravity is, by that means, encreaſed; and ſo they will be ſtopped from aſcending, and return back, either in form of dew, or drizzling rain; or remain ſuſpended ſome time in the form of a fog. Vapours may be ſeen on the high grounds as well as the low, but more eſpecially about marſhy places: they are eaſily diſſipated by the wind, as alſo by the heat of the ſun: they continue longeſt in the loweſt grounds, becauſe theſe places contain moſt moiſture, and are leaſt expoſed to the action of the wind.

Hence we may eaſily conceive, that fogs are only low clouds, or clouds in the loweſt region of the air; as clouds are no other than fogs, raiſed on high. See CLOUD.

When fogs ſtink, then the vapours are mixed with ſulphureous exhalations, which ſmell ſo. Objects viewed through fogs, appear larger and more remote than through the common air. Mr. Boyle obſerves, that upon the coaſt of Coromandel, and the moſt maritime parts of the Eaſt-Indies, there are, notwithſtanding the heat of the climate, annual fogs ſo thick, as to occaſion thoſe of other nations who reſide there, and even the more tender part of the natives, to keep their houſes cloſe ſhut up.

FOGAGE, in the foreſt law, is rank graſs not eaten up in ſummer.

FOIL, among glaſs-grinders, a ſheet of tin, with quickſilver or the like, laid on the backſide of a looking-glaſs, to make it reflect. See FOLIATING and LOOKING-GLASS.

FOIL, among jewellers, a thin leaf of metal placed under a precious ſtone, in order to make it look tranſparent and give it an agreeable different colour, either deep or pale: thus, if you want a ſtone to be made of a pale colour, put a foil of that colour under it; or if you would have it deep, lay a dark one under it.

Theſe foils are made either of copper, gold, or gold and

and ſilver together: the copper foils are commonly known by the name of Nuremberg or German foils; they are prepared as follows: procure the thinneſt copper plates you can get; beat theſe plates gently upon a well poliſhed anvil, with a poliſhed hammer, as thin as poſſible; and placing them between two iron plates as thin as writing-paper, heat them in the fire; then boil the foils, in a pipkin, with equal quantities of tartar and ſalt, conſtantly ſtirring them till by boiling they become white; after which, taking them out, and drying them, give them another hammering, till they are made fit for your purpoſe: however, care muſt be taken not to give the foils too much heat, for fear of melting, nor muſt they be too long boiled, for fear of attracting too much ſalt.

The manner of poliſhing theſe foils is as follows: take a plate of the beſt copper, one foot long and about five or ſix inches wide, poliſhed to the greateſt perfection; bend this to a long convex, faſten it upon a half roll, and fix it to a bench or table; then take ſome chalk, waſhed as clean as poſſible, and filtred through a fine linen cloth, till it be as fine as you can make it; and having laid ſome thereof on the roll, and wetted the copper all over, lay your foils upon it, and with a poliſhing ſtone and the chalk, poliſh your foils till they are as bright as looking-glaſs; after which they muſt be dried, and laid up ſecure from duſt.

FOLIATING *of Looking-Glaſſes* is performed by fixing quickſilver on the reverſe ſurface, by means of plates of tin; which amalgamating or combining with the quickſilver, takes away its fluidity, and renders it ſo tenacious, as to be compreſſed into a very thin coat or plate, capable of adhering to the ſurface of the glaſs.

There are ſeveral manners of laying the quickſilver and tin on the glaſs; and it is by ſome practiſed, to uſe the quickſilver alone; and by others, to compound with it tin and lead; and biſmuth has likewiſe been frequently uſed inſtead of them: but it is not neceſſary, when the operation is well conducted, to make any addition to the quickſilver. The following is one of the beſt methods hitherto practiſed.

"A proper number of ſheets of thin paper muſt be procured; which paper ſhould be of a ſoft ſpongy nature, like that called blotting paper. This paper muſt be ſpread on a table with a very level even ſurface, and fixed very firmly; or it is better to uſe a marble table or ſlab; but ſo much only of the table ſhould be covered, as may form an area of the ſame figure with that of the glaſs to be ſilvered, a little enlarged. Over the ſurface of the paper muſt be ſprinkled ſome powdered chalk; which ſhould be rolled or beaten very thin, muſt then be laid upon the paper ſprinkled with chalk, in the moſt ſmooth and even manner: and where there is occaſion, on account of the ſize of the glaſs, to uſe more than one, they ſhould be joined with great exactneſs, rather ſuffering nevertheleſs the edge of one to bear on the other, than leaving any deficiency; ſo that the whole ſurface of the paper may be perfectly covered. Quickſilver is then to be poured upon theſe leaves of tin; and ſpread over every part of it by a hare's foot, or the feathered part of a quill. The ſheets of every thin ſmooth paper, of which the kind called fan paper is beſt, muſt be then laid over the quickſilver, leaving a margin beyond the quickſilver; and upon this paper the glaſs muſt be gently laid: and then, being preſſed down with the one hand, the paper muſt be gently drawn from under it with the other, by taking hold of the margin left for that purpoſe. The upper ſurface of the glaſs muſt then be covered with thicker paper, and a conſiderable weight put over it, in order to preſs out all the quickſilver that is not fixed by the tin; as well as to make it adhere the more firmly to the glaſs. When no more quickſilver appears to drain off, the weights and paper may be removed; and the operation will be complete."

Some, who uſe the biſmuth, add half an ounce of it to an ounce of the quickſilver, and make the amalgamation by melting the biſmuth, and then taking it off the fire, putting in the quickſilver gradually; and ſtirring it with an iron rod, or a tobacco-pipe, till the whole be thoroughly incorporated: when the maſs ſhould be poured into cold water, to prevent the quickſilver from ſubliming with the remaining heat. It is proper, nevertheleſs, before this compoſition be uſed, to ſtrain it through a cloth; and what remains, and will not be preſſed through, may be added to the next quantity to be incorporated. The proportion of tin and lead, when they are uſed in the ſame manner, is generally a compound of equal parts, in the proportion, when together, of a fourth part of the weight of the quickſilver. It has been alſo formerly practiſed, to uſe a compoſition of two parts of biſmuth, and one part of tin, with the ſame quantity of lead, and ten parts of the quickſilver.

Where the glaſſes with angular ſurfaces, called diamond-cut, are to be ſilvered, a border muſt be formed on the table of the figure of the glaſs, which may be done by a moveable frame. The paper, leaves, &c. muſt be brought over this border, and the ſubſequent proceeding may be the ſame, as in the caſe of the plain ſurface; only taking great care that the glaſs be properly let down within the border, ſo as to bear every where both on that and the ſurface of the table.

Globes of glaſs may be ſilvered; but as no preſſure can be given, the plates of tin cannot be uſed; and the quickſilver muſt therefore be rendered of a proper conſiſtence, by amalgamating it with ſome of the other metallic ſubſtances. The moſt approved method of doing this is as follows.

"Take of quickſilver two parts, of biſmuth two parts, and of tin and lead each one part. Melt the tin and lead together, and when they are fluid, add the biſmuth; when that is melted likewiſe, take them from the fire, and put the quickſilver gradually to them; ſtirring the mixture till the whole be united. After the maſs is become ſo cool, as not to endanger its breaking the glaſs, pour it into the globe to be ſilvered; uſing a funnel, which will carry it to the bottom of the globe. Move the glaſs then gently about, ſo that the amalgamated matter may flow over every part, and adhere to it; which will effectually ſilver the globe. When every part is covered, pour out the redundant quantity, and keep the glaſs ſtill, till it be perfectly cool. If, during the operation, the mixture is ſet in the globe, and be not ſufficiently liquid to flow about, and cohere with the glaſs, a gentle heat muſt be adminiſtred, which will remedy this defect; and if, on the contrary, the matter appear too fluid, and have not ſufficient tenacity to fix itſelf to the glaſs, it muſt be taken out, and an additional quantity of the biſmuth, tin, and lead, added, by means of a proper heat."

FOLIATION, a term uſed by ſome botaniſts to denote the corolla, or flower-leaves. See FLOWER and COROLLA.

FOLIO, in merchant books, denotes a page, or rather both the right and left hand pages, theſe being expreſſed by the ſame figure, and correſponding to each other. See BOOK-KEEPING.

FOLIO, among printers and bookſellers, the largeſt form of books, when each ſheet is printed, that it may be bound up in two leaves only.

FOLLICLE, *Folliculus*, among botaniſts, denotes a kind of ſeed veſſel, like the conceptaculum. See CONCEPTACULUM.

FOMAHANT, or FOMALHANT, in aſtronomy, a ſtar of the firſt magnitude in Aquarius, whoſe latitude is 29°. 19'. 11". north, and longitude 27°. 23'. 24". of Capricornus, according to Mr. Flamſtead's catalogue.

FOMENTATION, in medicine, the ſame with a liquid epithema, if applied hot; and is the bathing of any part of the body in a proper liquor, commonly made by a decoction of herbs in water, wine, milk, &c. being generally applied by means of ſtupes or doubled flannels, dipped in the medicated decoction, and all the liquor, if very hot, expreſſed out of them, leſt it ſhould ſcald the part, raiſe bliſters, &c. And it is farther obſervable, that a certain degree of heat will diſſolve and diſſipate a tumour, whilſt a higher degree of it will harden and make it ſchirrous.

The word is Latin, *fomentatio*, and derived from *fomento*, to foment.

FONT, among eccleſiaſtical writers, a large baſon in which water is kept for the baptizing of infants, or other perſons.

It is ſo called probably becauſe baptiſm was uſually performed among the primitive Chriſtians at ſprings or fountains.

FONTANELLA, in anatomy, the quadrangular aperture, between the os frontis and oſſa ſincipitis, in infants juſt born, which is alſo called fons pulſatilis.

FONTICULUS, or FONTANELLA, in ſurgery, an iſſue, ſeton, or ſmall ulcer made in various parts of the body, in order to eliminate the latent corruption out of it. See ISSUE, SETON, &c.

FONTINALIA, in Roman antiquity, a religious feaſt celebrated on October 13, in honour of the nymphs of wells and fountains.

FOOD implies whatever aliments are taken into the body, to nouriſh it. See DIET, DRINK, ALIMENT, &c.

FOOT, *Pes*, a part of the body of moſt animals whereon they ſtand, walk, &c.

FOOT, *Pes Magnus*, or great foot, in anatomy, denotes the extent from the juncture of the hip to the toe ends; but the foot, or leſſer foot properly ſo called, is divided into three parts, that is, tarſus, metatarſus, and toes.

The tarſus is the ſpace between the bones of the leg and the metatarſus; it is compoſed of ſeven bones. The firſt is called aſtragalus or talus; in its upper part it has a convex head, which is articulated with the two ſociles of the leg by ginglymus, being divided by a little ſinus which receives the ſmall protuberance in the middle of the ſinus of the tibia. And without this articulation we muſt always, in walking, have trod upon the heel with our fore foot, and upon our toes with our hind foot. The fore part of the aſtragalus, which is alſo convex, is received into the ſinus of the os naviculare. Below, towards the hind part of its under ſide, it has a pretty large ſinus, which receives the upper and hind part of the os calcis. But towards the fore part of the ſame ſide it has a protuberance, which is received into the upper and fore part of the ſame bone. Betwixt this ſinus and this protuberance, there is a cavity which anſwers to another in the os calcis, in which is contained an oily and mucous ſort of ſubſtance for moiſtening the ligaments, and facilitating the obſcure motion of theſe bones when we walk.

The ſecond bone of the tarſus is the calcaneum, os calcis, or heel-bone; it is the largeſt of the bones of the tarſus. It lies under the aſtragalus, to which it is articulated by ginglymus, as we have already deſcribed. Behind it is a large protuberance, which forms the heel, and into which the tendo achillis is inſerted; and before it, is a cavity which receives a part of the os cubiforme.

The third is the os naviculare or cymbiforme; it lies between the aſtragalus and the three oſſa cuneiformia: behind it is a large ſinus, which receives the fore convex head of the firſt; and before it is convex, diſtinguiſhed into three heads, which are received into the ſinus's of the oſſa cuneiformia.

The fourth, fifth and ſixth are called oſſa cuneiformia, becauſe they are large above, and narrow below; they lie all three at the ſide of one another; their upper ſide is convex, and their under hollow, by which means the muſcles and tendons in the ſole of the foot are not preſſed when we walk. At one end they have each a ſinus, which receives the os naviculare, and at the other end they are joined to the three inner bones of the metatarſus; the inmoſt of theſe bones is the biggeſt, and that in the middle the leaſt.

The ſeventh bone is called the os cubiforme, becauſe of its figure; it lies in the ſame rank with the oſſa cuneiformia: behind it is joined to the os calcis, before to the two outer bones of the metatarſus, and on its inſide is joined to the third os cuneiforme.

The bones of the metatarſus are five; that which ſuſtains the great toe is the thickeſt, and that which ſuſtains the next toe is the longeſt, the reſt grow each ſhorter than the other. They are longer than the bones of the metacarpus; in other things they are like them, and they are articulated to the toes, as they are to the fingers.

The bones of the toes are fourteen. The great toe has two, and the reſt have each three; they are like the bones of the fingers, only they are ſhorter.

In the toes there are ſometimes found twelve oſſa ſeſamoïdæa, as in the fingers.

FOOT, in the Latin and Greek poetry, a metre or meaſure, compoſed of a certain number of long and ſhort ſyllables.

Theſe feet are commonly reckoned twenty-eight, of which ſome are ſimple, as conſiſting of two or three ſyllables, and therefore called diſyllabic or triſyllabic feet; others are compound, conſiſting of four ſyllables, and are therefore called tetraſyllabic feet.

The diſyllabic feet are four in number, viz. the pyrrhichius, ſpondeus, iambus, and trocheus. See PYRRHICHIUS, &c.

The triſyllabic feet are eight in number, viz. the dactylus, anapæſtus, tribrachys, moloſſus, amphybrachys, amphimacer, bacchius, and antibacchius. See DACTYL, &c.

The tetraſyllabic are in number ſixteen, viz. the procleuſmaticus, diſpondeus, coriambus, antiſpaſtus, diiambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus ſecundus, epitritus tertius, epitritus quartus, pæon primus, pæon ſecundus, pæon tertius, and pæon quartus. See the articles PROCLEUSMATICUS, &c.

There are ſeveral other ſorts of feet invented by idle grammarians, of five, ſix, or more ſyllables, but they are not worth the reciting. The number of feet each ſort of verſe contains, will be found under that particular verſe. See the articles HEXAMETER, &c.

Even and odd FOOT, in poetry, is a foot ſo denominated in reſpect of its ſituation in the verſe: thus, the firſt, third, and fifth foot of the verſe are uneven. This denomination of feet chiefly obtains in iambic verſe. See IAMBIC.

FOOT is alſo a long meaſure, conſiſting of 12 inches. See the article INCH.

Geometricians divide the foot into 10 digits, and the digit into 10 lines. See the articles DIGIT and LINE.

FOOT *Square* is the ſame meaſure, both in breadth and length, containing 144 ſquare or ſuperficial inches.

Cubic or *Solid* FOOT is the ſame meaſure in all the three dimenſions, length, breadth, and depth or thickneſs, containing 1728 cubic inches.

The foot is of different lengths in different countries. The Paris royal foot exceeds the Engliſh by nine lines; the ancient Roman foot of the Capitol, conſiſted of 4 palms, equal to 11 $\frac{4}{10}$ inches Engliſh; Rhineland or Leyden foot, by which the northern nations go, is to the Roman foot as 950 to 1000. The proportions of the principal feet of ſeveral nations, compared with the Engliſh, are as follow.

The Engliſh foot being divided in 1000 parts, or into 12 inches, the other feet will be as follow:

	1000 parts.	Feet.	inch.	lines.
London-foot	1000	0	12	0
Amſterdam	942	0	11	3
Antwerp	946	0	11	2
Bologna	1204	1	2	4
Bremen	964	0	11	6
Cologne	954	0	11	4

FOOT-BANK, or FOOT-STEP, in fortification, the ſame with banquette. See the article BANQUETTE.

FOOT-HUSKS, among botaniſts, ſhort heads, out of which flowers grow.

FOOT-LEVEL, among artificers, an inſtrument that ſerves as a foot-rule, a ſquare, and a level. See the articles LEVEL, RULE, and SQUARE.

FOOT-PACE, or HALF-PACE, among carpenters, a pair of ſtairs, whereon, after four or ſix ſteps, you arrive at a broad place, where you may take two or three paces before you aſcend another ſtep. The deſign of which is to eaſe the legs in aſcending the reſt of the ſteps. See the article STAIR-CASE.

FOOT-ROPES, among ſailors, the ſame with the horſes of the yards. See the article HORSE.

FORAMEN, in anatomy, a name given to ſeveral apertures, or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or ſkull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranæ tympani.

FORAMEN OVALE, an oval aperture or paſſage through the heart of a fœtus, which cloſes up after birth. It ariſes above the coronal vein, near the right auricle, and paſſes directly into the left auricle of the heart, ſerving for the circulation of the blood in the fœtus, till ſuch time as the infant breathes and the lungs are open; it being generally reckoned one of the temporary parts of the fœtus, wherein it differs from an adult, although almoſt all anatomiſts, Mr. Cheſelden excepted, aſſure us, that the foramen ovale has ſometimes been found open in adults.

The foramen ovale therefore, and the canal of communication in the fœtus are in reality no other than a ſort of ſubſidiary parts to the lungs formed only for a certain time, and to become uſeleſs and diſappear when the act of reſpiration has given the turn to the circulation of the blood, which it is to retain through the whole life of the animal. Dr. Trew affirms, that the membrane of the foramen ovale is ſo placed, as to permit the blood to paſs freely from the right auricle to the left, during the diaſtole of the auricles, but never from the left auricle to the right. See Phil. Tranſ. N° 457.

FORCE *of Bodies in Motion.*—It has been a famous diſpute among philoſophers, "Whether the force of bodies in motion, ſtriking each other, be proportional to the ſimple velocity of the motion, or to the ſquare of the velocity?" The Engliſh and French maintain the former, the Dutch and Germans the latter.

This diſpute firſt commenced between Mr. Huygens and the abbot Catalan, about the force of oſcillating bodies; it continued ſome time between theſe two gentlemen; at length, another ſubject of the ſame kind engaged the ſaid abbot with the famous Leibnitz, who is to be eſteemed the firſt author that plainly declared, in expreſs words, "That the forces of bodies were as their maſſes multiplied by the ſquare of the velocity."

Catalan, and afterwards Mr. Papin, anſwered Leibnitz; he replied again, and ſeveral papers were written on the ſubject. It then became a matter of general enquiry, and the philoſophers of every nation began to conſider which ſide to be of, and whether they ſhould declare for the old or for the new opinion. However, they did here, as they do in religion, go by a whole nation together; the common herd of philoſophers following the dictates of their leaders. Thus Leibnitz, Polenus, s'Graveſande, and Muſchenbroek led the German and Dutch; Papin, Mairan, &c. the French; and Pemberton, Eames, Deſaguliers, Clarke, &c. the Engliſh.

As it uſually falls out in other caſes, ſo here, when men find themſelves preſſed with difficulties and abſurdities in their ſchemes and notions, they have recourſe to the ſubtilties of metaphyſical diſtinctions, though ſeldom to any good purpoſe. Thus when it appeared too plainly by all experiments, and even to common ſenſe, that the natural force of bodies was proportional to the ſimple velocity and maſs of matter conjointly; we were told it was neceſſary to diſtinguiſh the force of bodies into two kinds, viz. the vis viva or living force; and the vis mortua, or the dead force.

By this vis viva, or living force, we were to apprehend that which reſulted from the viſible action of one body upon another, as that of a falling weight; but the vis mortua or dead force was to be underſtood of that which was deſtroyed by a contrary agent, as a weight in one ſcale of a balance is kept from deſcending by a counterpoiſe in the other ſcale. But, unluckily for the author of this refinement, both thoſe forces appear, even by the balance, to be in the ratio of the ſimple velocity into the maſs.

Thus for the living force, if on the proportional balance you place 4 ℔. at the diſtance of ſix inches on one ſide, and 2 ℔. at the diſtance of twelve inches on the other ſide, and, if the balance be put into motion, they will each of them have a vis viva, or an active force, becauſe they will keep the beam in motion for ſome time, till, by militating, they murder or kill each other; and then ſurely enough they become vires mortuæ, or dead forces.

But let us ſee how they exerted their power, while living. One (A) acted againſt the other (B), with the gravity of every particle in a maſs of 4 ℔. and with the velocity in each ſtroke that ſix inches diſtance could give; but, ſince all allow the weight to be as the maſs of matter, and the velocity as the diſtance from the center of motion, therefore all the force which A exerted was as $4\times6=24$. In the ſame manner it is ſhewn the whole force of B acting againſt A was as $2\times12=24$; that is, in each caſe, the force was as the velocity into the maſs of matter: and, becauſe they were equal, they deſtroyed each other.

But, had thoſe combatants A and B been armed with forces proportioned to the ſquares of the velocities, that of A would have been but $4\times6\times6=144$; whilſt B would have had a force equal to $2\times12\times12=288$; by which he would have demoliſhed A at one ſingle ſtroke, and been the ſurviving conqueror.

Let us now conſider theſe two bodies A and B as dead, and ſee what forces they exert in that ſtate. In order to this they muſt be hanged upon the arms of the balance, one on each ſide, till they are dead, i. e. motionleſs; but this will not happen till their diſtances from the center of motion become reciprocally proportional to their maſſes of matter; and then it is plain the caſe is the ſame as before; for the dead force of A will be as $4\times6=24=2\times12=$ dead force of B. Whereas, if theſe forces were as the maſſes into the ſquare of the velocities, A of 4 ℔. and B of 2 ℔. ought to die at the diſtances 6 and 8, 4 inches from the center reſpectively; but, if the experiment be tried there, ſuch ſtrong ſymptoms of life will be found in A, as manifeſt the falſity of this hypotheſis.

Being driven from this ſubterfuge, they ſeek another in a critical diſtinction between force and preſſure. Preſſure, ſay they, is the power with which bodies act by means of inſtruments; thus a weight in one ſcale acts againſt the weight in another by preſſure; but the power by which bodies act on each other alone, is properly called Force, as when one ſtone ſtrikes another by falling on it, or a hammer ſtrikes an anvil. The former they allow is proportional to the velocity and maſs of matter conjointly; but the latter, they ſay, is as the maſs multiplied by the ſquare of the velocity.

But this eclairciſſement boots them as little as the former, if they mean a momentary impact or ſtroke, or ſuch whoſe effect is produced in a moment of time. For in ſuch a caſe we ſay, the ſtroke is in proportion to the maſs of matter, and alſo to the degree of velocity, and therefore as both conjointly; but we deny there is any other ſource of power from whence a body can derive any force for producing a momentary effect: nor have any of thoſe gentlemen been able to ſhew there is, though ſome, bewildered in the labyrinth, have attempted it, but in how weak and ridiculous a manner may be ſeen in a piece intitled, De conſervatione virium vivarum, &c. And it is worth the reader's while to ſee the jocular confutation of this ludicrous piece by Phileleutherus Londinenſis.

If they ſay, they would not be underſtood of momentaneous effects, but ſuch as are produced in time, then they have no antagoniſts. And, it is plain from their experiments, that this is their meaning, after all. For their experiments, which they ſo much inſiſt on, are ſuch as are made by letting bodies fall on ſoft ſubſtances, as clay, butter, &c. or by the action of bodies on yielding ſprings, or ſpringy bodies; in all which caſes, the effect

is

is not produced inſtantaneouſly, but in time; the clay takes time to recede, the ſpring to bend, &c.

If the time be taken into conſideration, then every body muſt know that the effect will be proportional to the intenſity of the cauſe, and the time of its continuance: thus, for example, the effect of gravity on bodies left to themſelves cauſes them to deſcend; their deſcent therefore will be proportionate to the power of gravity upon them, and therefore greater in thoſe which fall freely, than in others which deſcend on inclined planes in a given time, where part of the force of gravity is deſtroyed by the re-action of the plane. But, ſince the action of gravity is not inſtantaneous, but continual, therefore its effect, i. e. the deſcent of the body, will be greater in proportion to the time of its continuing to act on the body, ſeparately conſidered from its intrinſic force. But this force is as the velocity produced by it in a given time; alſo the time is as the velocity, when the force is given; therefore the effect, viz. the deſcent of the body, is as the ſquare of the velocity.

Or in ſymbols thus: let E = the effect produced by any power = P, acting in any ſpace of time = T, upon any body = Q, moving with any degree of velocity V. Then it is plain, E will be as Q = maſs of matter in the body, when P, T, and V are given; alſo the effect E will be as the intenſity of the power P, when T, Q, and V are given; again, when P, Q, T are given, E muſt be as V; and laſtly, we ſhall have E as T, when P, Q, V are given. Therefore, when neither of theſe are given, E : Q × P × V × T; and, in caſe of any different effect, let $e : q \times p \times v \times t$.

Then ſuppoſing the bodies equal, viz. $Q = q$, we have $E : e :: P V T : p v t$. Thus the ſame or two equal bodies, deſcending on two planes unequally inclined, will deſcend through ſpaces, which will be as the different powers of gravity P and p, as the different velocities V and v in any point of time, and as the different times T and t of their deſcent, conjointly.

If not only the bodies Q and q, but alſo the powers P and p which actuate them, be ſuppoſed equal, or $P = p$; then $E : e : T V : t v$. Thus, in equal bodies falling freely by gravity, the effect, or the ſpace which they deſcribe, will be as the time T and t of the falls, the velocities V and v at any point of time in the fall. And becauſe in this caſe the velocity is always proportional to the time, that is, $T : t :: V : v$; if we multiply each ratio by the ſame ratio $V : v$, the analogy will ſtill be the ſame. viz. $T V : t v :: V^2 : v^2$; whence $E : e :: V^2 : v^2$; or the effect of falling bodies, in deſcribing the ſpace, will be as the ſquare of the velocities.

If we ſuppoſe the times given, that is, $T = t$, then (the reſt as before) we have $E : e :: V : v$; that is, the forces or effects of equal bodies, falling in equal times, are proportional to the ſimple velocities.

If $V = v$, or the velocities given, then $E : e :: T : t$. Thus, if two equal bodies, lying on an horizontal plane, receive a ſtroke each from ſprings of equal force, then will the velocites be equal in every part of the motion, and the effects E and e, in this caſe, being the ſpaces deſcribed, will be as the times of their motion.

Hence we have ſeen every poſſible caſe wherein the forces of bodies or their effects can be ſuppoſed to vary; and it is plain there is none where the force is as the ſquare of the velocity but where the time is concerned; or where ſome one of the factors Q, P, V, T, is proportional to the velocity; thus in ſpouting-water, becauſe Q is always as V, therefore, though T be given, E will be as QV, or as V^2; for P alſo in this caſe is given, the power of gravity which gives motion to the particles of the fluid being always conſtant. Nor have they any experiment which ſhews the force or effects of bodies proportional to the ſquares of the velocities, but where the time in which the effect is produced ought to be conſidered. Thus in their famous experiment of cavities, formed in ſoft clay by falling bodies, it is true, thoſe cavities are the effect of the falling bodies, and proportional to the ſquares of the velocity. But what is this to the purpoſe, unleſs they will ſay, thoſe pits are inſtantaneouſly produced, which we preſume none will pretend to do?

It is evident, this cavity muſt be proportional to the quantity of matter put in motion in the clay, by the falling body; but this is proportional to the velocity on two accounts; the firſt is, that every particle which comes in contact with the ſtriking body, receives a ſtroke proportional to the velocity; therefore alſo the number of particles which each of theſe can move, will be as the force of the ſtroke, or as the velocity of the falling body. Secondly, among yielding particles, the number which the falling body can apply to in a given time, will be as the velocity; conſequently the whole number of particles which can be moved, both immediately by the body itſelf, and by the motion communicated to the particles, will be as the ſquare of the velocity; and therefore the cavity will be in the ſame ratio alſo.

We hence obſerve, the ſame method of reaſoning may be applied to ſoft and yielding ſubſtances, as has always been uſed in the caſe of unelaſtic fluids; and for this reaſon only, that, in every caſe of yielding particles, the effect of a body in ſtriking them is not deſtroyed momentaneouſly, but in time, which time, cæteris paribus, will be as the velocity; and therefore, E being as T V, and T, in all theſe caſes, being as V, it will be univerſally for all ſoft and yielding ſubſtances $E : V^2$.

Hence we may obſerve, that as bodies are more or leſs yielding or ſoft, ſo the effect will be more or leſs approaching to the ratio of the ſquare of the velocity. This conſideration is of great uſe in mechanical affairs. Thus a hammer with a double velocity will produce much more than a double effect in driving a nail; the ſame may be ſaid of a rammer driving a pile: hence the reaſon why a ſmaller hammer will by its velocity do more execution upon a red-hot iron, than the large hammer by its momentum. In ſhort, all theſe things are ſo plain and eaſy to be underſtood, that is ſurprizing to think how ſuch a diſpute could ſubſiſt ſo long, and occaſion ſo much to be ſaid about it.

The learned Dr. Jurin, in the Philoſophical Tranſactions, N° 476, propoſes the following experiment, which he looks upon as ſufficient to put a final end to his controverſy, which has now ſubſiſted above ſeventy years.

Upon an horizontal plane, at reſt, but moveable with the leaſt force, ſuppoſe upon a boat in a ſtagnant water, let there be placed, between two equal bodies, a bent ſpring, by the unbending of which the two bodies may be puſhed contrarywiſe.

In this caſe it is evident, that the velocities, which the two bodies receive from the ſpring, will be exactly equal and their moving forces will alſo be exactly equal; and that the plane they move upon, and alſo the boat upon which it lies, will have no motion given them either way. Let us call the velocity of each body 1, and the moving force alſo 1.

Now, let us ſuppoſe the ſpring to be bent afreſh to the ſame degree as before, and to be again placed between the two bodies lying at reſt; then let the plane, upon which the ſpring and the bodies lie, be carried uniformly forwards, in the direction of the length of the ſpring, with this ſame velocity 1. In this caſe it is manifeſt, that each of the bodies will have the velocity 1, and the moving force 1, both in the direction of the axis of the ſpring.

During this motion, let the ſpring again unbend, and puſh the two bodies contrary ways, as before, the one forwards, the other backwards: then the ſpring will give to each of theſe bodies the velocity 1, as before when the plane was at reſt.

By this means the hindmoſt body, or that which is puſhed backwards, will have its velocity 1, which it had before by the motion of the plane, now intirely deſtroyed, and will be abſolutely at reſt.

But the body, which is puſhed forwards, will now have the velocity 2, namely, 1 from the motion of the plane, and 1 from the action of the ſpring.

Thus far every body agrees in what will be the event of this experiment.

But the queſtion is, what will be the moving force of the foremoſt body, or of that which is puſhed forwards, and which has the velocity 2; viz. 1 from the motion of the plane, and 1 from the action of the ſpring?

By the Leibnitian doctrine, its moving force muſt be

4: and, if ſo, it muſt have received the moving force 3 from the action of the ſpring; for it had only the moving force 1 from the motion of the plane.

Let us examine, whether this be poſſible, or reconcileable to their own doctrine.

Their doctrine is, that equal ſprings, equally bent, will, by unbending themſelves, give equal moving forces to the bodies they act upon, whatever thoſe bodies are.

We agree to this, not generally indeed; but in the caſe before us, where the bodies are of equal maſſes or weights, we agree to it.

Let us therefore imagine the bent ſpring, which is placed between the two bodies, to be divided tranſverſly into two equal parts. In this caſe it is plain, that the two halves of the ſpring may be conſidered as two intire ſprings, equal, and equally bent, each of which reſts at one end in equilibrio againſt the other ſpring, and, at the oppoſite end, preſſes againſt the body it is to move.

Conſequently, by the Leibnitian doctrine, to which, in this particular caſe where the bodies are equal, we alſo agree, the two ſprings will give equal moving forces to the two bodies. But the moving force, received by the hindmoſt body from the hinder ſpring, was undoubtedly the moving force 1: for, by that force given it in the direction backwards, the moving force 1, which it had before from the motion of the plane in the direction forwards, is exactly balanced and deſtroyed, the body remaining, as was obſerved before, in abſolute reſt. Therefore the moving force, received by the foremoſt body from the foremoſt ſpring, was alſo the moving force 1. And this, added to the other moving force 1, which it had before from the motion of the plane, makes the moving force 2, and not the moving force 4, as the Leibnitian philoſophers pretend.

Conſequently, that body, which had before the velocity 1, and the moving force 1, and now has the velocity 2, has alſo the moving force 2: that is, the moving forces are proportional to the velocities.

Attractive FORCE, *Central* FORCE, *Centrifugal* FORCE, *Centripetal* FORCE, FORCE *of the Heart*, FORCE *of the Wind*, } See { ATTRACTION. CENTRAL *Force*. CENTRIFUGAL *Force*. CENTRIPETAL *Force*. HEART. ANEMOMETER.

FORCE, in law, ſignifies any unlawful violence offered to things or perſons.

FORCEPS, in ſurgery, &c. an inſtrument that is well known, of which there are ſeveral ſorts, adapted to various operations. Their uſes are to lay hold of any thing and extract it from the body.

FORCER, or FORCING-PUMP, in mechanics, is a kind of pump in which there is a forcer or piſton, without a valve. See PUMP.

FORCIBLE, in law, ſomething done illegally. See the article FORCE.

FORCING, among gardeners, ſignifies the making trees produce ripe fruit before their uſual time. This is done by planting them in a hot bed againſt a ſouth-wall, and likewiſe defending them from the injuries of the weather by a glaſs frame. They ſhould always be grown trees, as young ones are apt to be deſtroyed by this management. See HOT-BED.

The glaſſes muſt be taken off at proper ſeaſons, to admit the benefit of freſh air, and eſpecially of gentle ſhowers.

FORCING *of Wine*. See WINE.

FORE-CASTLE, in ſhip-building, a ſhort deck which reaches from the top of the ſtem to the after part of the fore-ſhrouds; or it commonly reaches as far behind, or abaft, the fore-maſt, as it is from the maſt to the upper part of the ſtem.

FORE-CLOSED, in law, ſignifies the being ſhut out, and excluded, or barred, the equity of redemption on mortgages, &c.

FORE-FOOT, in ſhip-building, a piece of crooked timber, the lower part of which is bolted to the fore-end of the keel, of which it is a part, and the upper part laid on and bolted to the foot of the ſtem, of which it is alſo a part. See this fully explained in the article SHIP-BUILDING.

FOREIGN, in general, is applied to a perſon born in ſome other prince's dominions, or any thing brought from thence, and is oppoſed to native. In phyſic it is applied to any preternatural ſubſtance, either from without, or generated internally in the human body.

FOREIGN *Appoſer*, or *Oppoſer*, an officer in the court of Exchequer, to whom all ſheriffs and bailiffs repair to be appoſed by him of their green wax, after they have been appoſed of their ſums out of the Pipe-Office; and from thence he draws down a charge upon one of them to the clerk of the Pipe. His buſineſs is alſo to examine the ſheriff's eſtreats with the record, and to aſk the ſheriff what he ſays to every particular ſum therein.

FOREIGN *Plea*, a refuſal of the judge as incompetent, becauſe the matter in hand was not within his precinct.

FOREIGN *Service*, is ſuch ſervice, whereby a mean lord holdeth of another, without the compaſs of his own fee; or that which a tenant performeth either to his own lord, or to the lord paramount of his own fee.

FOREIGNER, the natural born ſubject of ſome foreign prince.

FORE-JUDGED, in law, ſignifies a judgment, whereby one is deprived, or put by a thing in queſtion.

FORELAND, in the ſea-language, the ſame with a cape. See the article CAPE.

FORELAND in fortification, the ſame with liziere. See the article LIZIERE.

FORE-LOCKS, little wedges of iron thruſt to the ends of the bolts in a ſhip's ſide, to prevent them from drawing as the ſhip labours at ſea.

FORELORN-*Hope*, in the military art, ſignifies men detached from ſeveral regiments, or otherwiſe appointed, to make the firſt attack in day of battle; or at a ſiege, to ſtorm the counterſcarp, mount the breach, or the like.

They are ſo called from the great danger they are unavoidably expoſed to; but the word is old, and begins to be obſolete.

FORE-MAST. See the article MAST.

FORE-REACHING, or, in the ſea-language, the act of making a greater progreſs forward than another ſhip; as the Tartar fore-reaches on the Eagle, i. e. advances quicker, or gains ground of her.

FORE-SKIN, in anatomy, the ſame with prepuce. See the article PREPUCE.

FOREST, *Sylva*, in general, a great wood, or a large extent of ground covered with trees.

FORE-STAFF, or CROSS-STAFF, a mathematical inſtrument uſed to take the ſun's altitude.

This inſtrument conſiſts of a ſtaff and four croſſes, viz. the tenth croſs, the thirtieth croſs, the ſixtieth croſs, and the ninetieth croſs.

The ſtaff is a ſquare piece of wood on which the croſſes ſlide, each ſide being graduated into diviſions: the firſt ſide has from about three degrees to ten delineated on it; the ſecond from ten to thirty; the third from twenty to ſixty; and the fourth from thirty to ninety.

The tenth croſs, ſo called from its belonging to that ſide of the ſtaff, which is numbered from three to ten degrees, is the ſhorteſt of the four croſſes, and is to be uſed when the ſun's altitude is under ten degrees. Sometimes the breadth of the thirtieth croſs ſupplies its place.

The thirtieth croſs is longer than that of ten, and belongs to that ſide of the croſs which is numbered from ten to thirty, whence it has its name: when the ſun's altitude is between ten and thirty degrees, this croſs is to be uſed.

The third, or ſixtieth croſs, ſo termed from belonging to that ſide of the ſtaff, which is numbered from twenty to ſixty, is longer than the former, and is to be uſed when the ſun's altitude is between thirty and ſixty degrees.

The fourth croſs is called the ninetieth croſs, becauſe it belongs to that ſide of the ſtaff which is numbered from thirty to ninety degrees. This croſs is uſed when the ſun's altitude is between ſixty and ninety degrees.

The ſeveral diviſions on the ſtaff are conſtructed after the following manner.

Let

Let A B (plate LXIV. *fig.* 7.) repreſent the ſide of the ſtaff to be divided; with any convenient radius, ſetting one foot of the compaſſes in A, with the other deſcribe the ſemicircle D E C, and draw the diameter D A C, at right angles to A B: divide each quadrant into ninety equal parts or degrees; at the diſtance of half the length of the croſs, draw the lines F *f*, G *g*, parallel to A B, and from the center of the circle draw right lines through the ſeveral diviſions of the quadrants; and, from the interſections of thoſe right lines with the two parallel lines F *f*, G *g*, draw right lines interſecting the ſtaff A B, which will give the ſeveral diviſions: thus the line F G, interſecting the ſtaff A B, in the point *a*, will give the diviſion of twenty degrees, becauſe the angle F A G = twenty degrees: and after the ſame manner, and by making uſe of the length of the ſeveral croſſes, may the four ſides of the ſtaff be divided.

To take the ſun's altitude with the FORE-STAFF.—Having adapted the proper croſs to the ſtaff, apply the flat end of the ſtaff at A, (*fig.* 8.) to the outſide of the eye, the face being turned towards the ſun; look for the object at the upper end of the croſs at C, and at the lower end B for the horizon; but, if the ſky appear inſtead of the horizon, ſlide the croſs nearer to the eye; if the ſea appear, remove it farther from the eye, till the object appear at the end C, and, at the ſame time, the horizon at the end B; then will the croſs cut, on the ſide of the ſtaff proper to it, the degree and minute of altitude. But, if the meridian altitude be required, the obſervation muſt be continued, and as the object approaches the meridian, the ſky will appear at the end B, inſtead of the horizon; but, when the object begins to deſcend, the ſea will appear at the end B, and then is the obſervation finiſhed, and the croſs will cut the degrees, &c. of altitude.

FORESTALLER, a perſon who is guilty of foreſtalling.

FORESTALLING, in law, buying or bargaining for any corn, cattle, victuals, or merchandize, in the way as they come to fairs or markets to be ſold, before they get thither, with an intent to ſell the ſame again at a higher price.

FORESTER, a ſworn officer of the foreſt, appointed by the king's letters patent, to walk the foreſt at all hours, watch over the vert and veniſon; alſo to make attachments and true preſentments of all treſpaſſes committed within the foreſt.

FORE-TOP-MAST. See the article TOP-MAST.

FORFEITURE, properly ſignifies the effect of tranſgreſſing ſome penal law, and extends to lands or goods.

Forfeiture differs from confiſcation, in that the former is more general, whilſt confiſcation is particularly applied to ſuch things as become forfeited to the king's Exchequer; and goods confiſcated, are ſaid to be ſuch as no perſon claims.

FORFICULA, the ear-wig, in zoology, a troubleſome inſect, which takes its Engliſh name from its introducing itſelf into people's ears, where it cauſes a great deal of pain, and its Latin name, *forficula*, from its forked tail, which is a ſort of forceps, capable of pinching. The exterior wings are very ſhort or dimidiated, and wholly cover the inner ones. The antennæ are long and ſlender, conſiſting of thirteen or fourteen articulations.

FOREFIELD, among miners, the fartheſt place of a meer of ground.

FORGE, properly ſignifies a little furnace, wherein ſmiths, and other artificers of iron or ſteel, &c. heat their metals red hot, in order to ſoften and render them more malleable and manageable on the anvil. See FURNACE.

The forge uſed by the ſeveral operators in iron, is very ſimple: we ſhall inſtance in that of the blackſmiths, to which all the reſt are reducible, the conſtruction of which is as follows. The hearth or fire-place of the forge, marked A, (See plate of Smithery, *fig.* 9.) is to be built up from your floor with brick, about two feet and an half, or ſometimes more, according to the purpoſe you deſign to forge for: if your forge be intended for heavy work, your hearth muſt lie lower than it need be for light work: the forge may be of what breadth is thought convenient. It may be built with hollow arches underneath, to ſet ſeveral things out of the way: the back of it is built upright to the top of the cieling, and incloſed over the fire-place with a hovel, which ends in a chimney, to carry away the ſmoke, as at B. In the back of the forge, againſt the fire-place, is fixed a thick iron-plate, and a taper pipe in it, about five inches long, which pipe comes through the back of the forge at C. Into this taper pipe is placed the noſe or pipe of the bellows: the office of this tewel is to preſerve the pipe of the bellows and the back of the forge about the fire-place, from burning. Right before the back is placed, at about two feet diſtance, the trough, which reaches commonly the whole breadth of the forge, and is as broad as is thought neceſſary, as at D. The bellows is placed behind the back of the forge, having one of its boards ſo fixed, that it can neither move upwards nor downwards. At the ear of the upper board is faſtened a rope or chain at E, which reaches up to the rocker, and is faſtened there to the further end of the handle, at F. This handle is faſtened acroſs a rock-ſtaff, which moves between two cheeks upon the center pins, in two ſockets, at G; ſo that by drawing down this handle, the moving board of the bellows riſes; and by a conſiderable weight ſet on the top of its upper-board, ſinks down again, and by this agitation performs the office of a pair of bellows. See BELLOWS and SMITHERY.

FORGE is alſo uſed for a large furnace, wherein iron-ore, taken out of the mine, is melted down; or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and ſeparated in a former furnace, and then caſt into ſows and pigs, is heated and fuſed over again, and beaten afterwards with large hammers, and thus rendered more ſoft, pure, ductile, and fit for uſe.

Of theſe there are two kinds: the firſt is called the finery, where the pigs are worked into groſs iron, and prepared for the ſecond, which is called the chafery, where it is further wrought into bars fit for uſe. See the articles FORGING, FINERY, and CHAFERY.

FORGERY, in a legal ſenſe, is where a perſon fraudulently makes and publiſhes falſe writings to another's prejudice: or, it ſignifies the writ that lies againſt him who offends that way.

Forgery is either at common law, or by ſtatute; and is an offence puniſhable by indictment, information, &c. and not only where a perſon makes a falſe deed, but where any fraudulent alteration is made of a true one, in a material point thereof. Likewiſe a writing may be ſaid to be forged, where one being directed to draw up a will for another, does inſert ſome legacies therein falſely of his own head; though, in ſuch caſes, there is no forgery of the hand or ſeal of the party: but a perſon cannot regularly be guilty of this crime by an act of omiſſion, unleſs it alters the limitation of an eſtate to another, in which caſe it may be forgery. By a ſtatute of George II. c. 25. the forging or counterfeiting any deed, will, bond, bill, note, &c. with intent to defraud any perſon, or publiſhing ſuch falſe deed, bond, &c. knowingly, is declared to be felony; and the offender ſhall ſuffer death. The king may pardon the corporal puniſhment of forgery which tends to public example, though the plaintiff cannot releaſe it: yet, in an extraordinary caſe, a forgery has been compounded, and the defendant diſcharged on paying a ſmall fine.

FORGING, in ſmithery, the beating or hammering iron on the anvil, after having firſt made it red-hot in the forge, in order to extend it into various forms, and faſhion it into works. See FORGE.

There are two ways of forging and hammering iron; one is by the force of the hand, in which there are uſually ſeveral perſons employed, one of them turning the iron and hammering likewiſe, and the reſt only hammering. The other way is by the force of a water-mill, which raiſes and works ſeveral large hammers beyond the force of men; under the ſtrokes of which the workmen preſent large lumps, or pieces of iron, which are ſuſtained at one end by the anvils, and at the other by iron chains faſtened to the cieling of the forge. See MILL.

This laſt way of forging is only uſed in the largeſt works, as anchors for ſhips, &c. which uſually weigh

ſeveral thouſand pounds. For lighter works, a ſingle man ſerves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpoſe the work is deſigned for, requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the ſmiths call it, when it will not batter under the hammer; and if it be too hot, it will red-ſear, that is, break or crack under the hammer.

The ſeveral degrees of heats the ſmiths give their iron, are, firſt, a blood-red heat; ſecondly, a white flame heat; and thirdly, a ſparkling or welding heat. See the article HEAT.

FORM, *forma*, in phyſics, the eſſential or diſtinguiſhing modification of the matter whereof a natural body is compoſed, ſo as thereby to give it ſuch a particular manner of exiſtence, being that which conſtitutes it ſuch a particular body, and diſtinguiſhes it from every other body.

FORMS *of Syllogiſms*, or *Syllogiſtic* FORM, among logicians, a juſt diſpoſition both of the terms, in reſpect of predicate and ſubject; and of the propoſitions, in reſpect of quantity and quality: by which is only meant a diſpoſition wherein the concluſion follows duly and legitimately from the two premiſes; there being no form, where there is no concluſion. See the article SYLLOGISM.

FORM, in theology, is ſaid to be one of the eſſential parts of the ſacraments; being that which gives them their ſacramental nature and efficacy, and conſiſting in certain words, which the prieſt pronounces in adminiſtering them.

FORM is alſo uſed in a moral ſenſe, for the manner of being, or doing a thing according to rules; thus we ſay, a form of government, a form of argument, &c.

FORM, in law, the rules eſtabliſhed and requiſite to be obſerved in legal proceedings.

FORM, in carpentry, is uſed to denote the long ſeats or benches in the choirs of churches, or in ſchools, for the prieſts, prebendaries, religious, or ſcholars, to ſit on.

At ſchools, the word form is frequently applied to what is otherwiſe termed a claſs. See CLASS.

FORM alſo denotes the external appearance or ſurface of a body, or the diſpoſition of its parts, as to the length, breadth, and thickneſs. See the article FIGURE.

FORM is alſo uſed among mechanics, for a ſort of mould, whereon any thing is faſhioned or wrought: as the hatter's form, the paper-maker's form, &c. See the article HATTER, &c.

Printer's FORM, an aſſemblage of letters, words, and lines, ranged in order, and ſo diſpoſed into pages by the compoſitor, from which, by means of ink and a preſs, the printed ſheets are drawn.

Every form is incloſed in an iron chaſe, wherein it is firmly locked by a number of pieces of wood; ſome long and narrow, and others of the form of wedges. See PRINTING.

FORMA PAUPERIS, in law, is where a perſon has juſt cauſe of ſuit, but is ſo poor that he cannot defray the uſual charges of ſuing at law or in equity; in which caſe, on making oath that he is not worth five pounds in the world, on all his debts being paid, and producing a certificate from ſome lawyer that he has good cauſe of ſuit, the judge will admit him to ſue in forma pauperis; that is, without paying any fee to counſellors, attorneys, clerks, &c.

FORMATION, in philoſophy, an act whereby ſomething is formed or produced.

FORMATION, in grammar, ſignifies the manner of forming one word from another: thus accountantſhip is formed from accountant, and this laſt from account.

FORMERS, in gunnery, round pieces of wood, fitted to the diameter of the bore of a gun, chiefly uſed for making cartridges.

On theſe formers, the paper, parchment, or cotton, which is to make the cartridge, are rolled before it be ſewed.

FORMICA, the ant, in zoology. See the article ANT.

FORMICA-LEO, the ant-lion, or ant-eater, in zoology, an inſect ſo called from its devouring great numbers of ants. It is the caterpillar or worm of a fly, much reſembling the libellæ, or dragon-flies.

FORMING *he line*, in naval affairs, drawing up the ſhips of a ſquadron or diviſion in a ſtrait line, about an hundred and twenty fathoms diſtance from each other. See the article LINE *of Battle*.

FORMULA, or FORMULARY, a rule or model, or certain terms preſcribed or agreed by authority, for the form and manner of an act; inſtrument, proceeding, or the like.

FORMULA, in medicine, imports the conſtitution of medicines, either ſimple or compound, both with reſpect to their preſcription and conſiſtence. Paracelſus calls red and clear urine, formula urinæ.

FORNICATION, the act of incontinency between ſingle perſons; for when either of the parties is married, ſuch act is adultery. See ADULTERY.

FORNIX, in anatomy, a part of the brain placed under the ſeptum lucidum, and, like it, compoſed of a medullary ſubſtance. Its anterior part riſes with a double baſe, but the two parts ſoon unite: the hinder part is likewiſe bifid, and thence called crura fornicis, and by ſome, pedes hippocampi. See the article BRAIN.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, graſs, clover, &c. brought into the camp by the troopers, for the ſuſtenance of their horſes.

Dry forage is the hay, oats, &c. delivered out of the magazines, to an army in garriſon, or when they take the field, before the green forage is ſufficiently grown up to ſupply the troops.

FORT, in the military art, a ſmall fortified place, environed on all ſides with a moat, rampart, and parapet. Its uſe is to ſecure ſome high ground, or the paſſage of a river, to make good an advantageous poſt, to defend the lines and quarters of a ſiege, &c.

FORTS are made of different figures and extents, according as the ground requires. Some are fortified with baſtions, others with demi-baſtions. Some again are in form of a ſquare, others of a pentagon. A fort differs from a citadel, as this laſt is built to command ſome town. See the article CITADEL.

Royal FORT, one whoſe line of defence is at leaſt twenty-ſix fathoms long.

To fortify a ſquare fort, having inſcribed the ſquare in a circle, 1. Divide each of its ſides A B, B D, &c. (plate LXV. *fig.* 1.) into two equal parts, in the point E. 2. From the center E, draw an indefinite line E F. 3. From the centre draw alſo the lines E A, E B, E D, E C, to the angles of the ſquare. 4. Divide the ſide A B into eight equal parts. 5 Let one of theſe parts be laid off from F to G, and from G draw the lines of defence A G, B G. 6. Divide another ſide of the ſquare into ſeven equal parts. 7. Lay off two of theſe parts from A to K, and from B to L, which will be the faces of the baſtions. 8. Take the diſtance K L in your compaſſes, and lay it off the lines of defence from K to H, and from L to I; and drawing H I, it will be the curtain; and the lines K H, L H, will be the flanks. See another method of fortifying a ſquare; alſo two different methods of fortifying a triangle, *fig.* 2.

Star-FORT, a redoubt formed by a number of re-entering and ſaliant angles, the ſides of which flank each other. See *fig.* 3.

To deſcribe a ſtar-fort, 1. Draw an hexagon *a* B C *de*[illegible] 2. Divide one of its ſides B C into four equal parts. 3. Upon the middle of this ſide, raiſe the perpendicular D A, equal to $\frac{1}{4}$ of the ſide B C, from D to A. 4. From the point A, draw the faces A C, A B. Let the ſame operations be performed with reſpect to the other ſides of the hexagon, and you will have the ſtar-fort required.

FORTIFICATION, the art of fortifying a town, or other place; or of putting them in ſuch a poſture of defence, that every one of its parts defends, and is defended by ſome other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a ſmall number of men within may be able to defend themſelves for a conſiderable time againſt the aſſaults of a numerous army without, ſo that the enemy, in attacking them, muſt of neceſſity ſuffer great loſs.

Fortification is either antient or modern, regular or irregular

5 1A 59

regular. Ancient fortification, at firſt, conſiſted of walls or defences made of trunks, and other branches of trees, mixed with earth, to ſecure them againſt the attacks of the enemy. This was afterwards altered to ſtone-walls, on which were raiſed breaſt-works, behind which they made uſe of their darts and arrows in ſecurity. Modern fortification, is that which is flanked and defended by baſtions and out-works, the ramparts of which are ſo ſolid, that they cannot be beat down but by the continual fire of ſeveral batteries of cannon.

Regular fortification, is that built in a regular polygon, the ſides and angles of which are all equal, being commonly about a muſket-ſhot from each other.

Irregular fortification, on the contrary, is that where the ſides and angles are not uniform, equidiſtant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like. See BASTION, &c.

The principal maxims of fortification are theſe: 1. That every part of the works be ſeen and defended by other parts, ſo that the enemy can lodge no where without being expoſed to the fire of the place. 2. A fortreſs ſhould command all places round it; and therefore all the out-works ought to be lower than the body of the place. 3. The works fartheſt from the center, ought always to be open to thoſe more near. 4. No line of defence ſhould exceed a point blank muſket-ſhot, which is about an hundred and twenty or an hundred and twenty-five fathoms. 5. The more acute the angle at the center is, the ſtronger will be the place. 6. In great places, dry trenches are preferable to thoſe filled with water, becauſe ſallies, retreats, and ſuccours are frequently neceſſary; but, in ſmall fortreſſes, water-trenches that cannot be drained, are beſt, as ſtanding in need of no ſallies, &c.

Different authors recommend different methods of fortification; but the principal are thoſe of Pagan, Blondel, Vauban, and Scheiter.

Fortification, according to the method of count Pagan, ſuppoſes the ſide A B (plate LXV. *fig.* 4.) of the external polygon, in larger fortifications, 100 perches; in the ſmaller, 80; and in thoſe of middle ſize, 90; with the correſponding faces, 30, 25, and 27 $\frac{1}{2}$; the perpendicular, C D, being in all of them 15. Here two of the flanks G F, H E, are perpendicular to the lines of defence, A E and B F: the flanks are alſo covered with an orillon, and are threefold. L M N is the boundary of the moat, parallel to the faces A G, B H. The curtain is defended by a double ravelin, O Q P being the external one, and *a c b* the internal; the faces of the baſtions being likewiſe defended by counter-guards, *g f*, *e d*.

This method, though received with great applauſe, is not without its defects. It is not only very expenſive, but its threefold flanks are too cloſe, ſo as to be too much expoſed to bombs; the largeneſs of the orillon is prejudicial to the length of the flanks, and the outer rampart is two thick.

Mr. Blondel's method of fortification has a great affinity with that of count Pagan, only that the lines and angles are otherwiſe determined. Thus by ſubtracting a right angle from that of the polygon, and adding 15 to a third part of the remainder, you find the quantity of the diminiſhed angle A B E. In the greater fortifications, the ſide A B (*fig.* 5.) of the outer polygon is 100 perches, in the leſſer only 85; and A B being divided into ten equal parts, ſeven of them give the lines of defence A F, B E. The faces of the baſtions A G, B H, are equal to half thoſe of the tenaille A D, B D. In theſe faces is a kind of flanking batteries Q R, to defend the faces of the ravelin *e c d*. The flanks H F, G E, are threefold, as in count Pagan's method; and in the middle of the moat is a deep trench *a d b*. The other out-works are as repreſented in *fig.* 6.

Fortification, according to Vauban's method, ſuppoſes the outer polygon to be 100 perches in larger places, 80 in ſmaller ones, and 90 in thoſe of a middle ſize. The faces are made $\frac{2}{7}$ of the ſame, the perpendicular $\frac{1}{8}$ in a ſquare, $\frac{1}{7}$ in a pentagon, and $\frac{1}{6}$ in other polygons. He alſo makes the complement of the face to the line of defence, equal to the diſtance of the epaule; uſes re-entering crooked flanks, and places a low tenaille before the curtain. See *fig.* 7.

This method of fortification is much eſteemed by many, both as it increaſes the ſtrength without much expence, and agrees very well with the maxims above laid down. Its greateſt fault conſiſts in this, that the faces lie altogether expoſed to the enemy.

Vauban's new method places large baſtions before ſmall ones; the curtain being covered with a low tenaille and a double ravelin, *fig.* 8.

Fortification, according to Scheiter's method, ſuppoſes the external ſide A B, (*fig.* 9.) in large fortifications, 110 perches; in leſſer ones, 80; and in thoſe of a middle ſize, 90. The flanks N O, P Q, are perpendicular to the lines of defence A Q, B O; which in greater fortifications are 70, in leſſer 60, and in thoſe of middle ſize, 65 perches; theſe detach the baſtions from the curtain, and form a kind of inner receſs behind the curtain. The angle of the baſtion in a ſquare, is 60°; in a pentagon, 72°; in a hexagon, 78°; in a heptagon, 83°; and in works of more ſides, this angle is found by adding 2° for every ſide above the heptagon.

As to the outworks, they are much the ſame as in the preceding methods, only that the covert-way is double; as is the ravel which covers the curtain.

To lay down the plan of a regular fortification. 1. Meaſure exactly the circuit of the place to be fortified, at about twelve paces diſtance from the houſes; and dividing the whole circuit by 150 geometrical paces at leaſt, or 180 at moſt, the quotient will give the number of the baſtions, in ſuch a manner that their lines of defence ſhall not exceed the carriage of a muſket ball. 2. Inſcribe in a circle a polygon, with as many ſides as the place is to have baſtions; and from the center A (*fig.* 10.) through the angle B of the polygon, draw lines at pleaſure, which lines are called principals. Afterwards take B *a* = $\frac{1}{8}$ of the ſide of the polygon, and B F = $\frac{1}{3}$; then drawing the lines of defence F *g a*, F *g a*, from each point *a* raiſe perpendiculars; which meeting the lines of defence in the points *g*, *g*, will form the baſtions *a g* F *g a*, *a g* F, &c. 3. Having thus deſcribed the outward circuit of the rampart, draw lines *e*, *e*, *e*, parallel to the faces of the baſtions F *g*, F *g*, F *g*: theſe will determine the outward circuit of the moat, which ought to be rounded before the angles of the baſtions F F. 4. To finiſh the plan, draw within the place lines parallel to thoſe which form the outward circuit of the rampart, at the diſtance of $\frac{1}{3}$ of the flank for the parapet; at the diſtance of $\frac{1}{2}$ the demigorge B *a*, for the rampart; and at the diſtance of five feet from the parapet, for the banquet. In the ſame manner, on the outſide of the moat, muſt be drawn lines parallel to its outward circuit, at the diſtance of $\frac{1}{4}$ of the flank for the covered way; and at the diſtance of $\frac{2}{3}$ of the flank for the glacis.

To lay down the profile of theſe works.—Let A R R (*fig.* 11.) repreſent the level of the place; take A B, 5 paces, for the place of arms; the perpendicular O C, 16 feet, for the talus or ſlope; the thickneſs of the lower part of the rampart, B R, 12 paces; the upper part, C D, 6 $\frac{2}{3}$ paces; the banquet, *d* D, 6 feet; the thickneſs of the lower part of the parapet D V, 3 $\frac{1}{3}$ paces; the upper, at E, 2 $\frac{1}{3}$ paces; its inward height, E D, 6 feet; and its outward height, 5 feet; the talus of the rampart to the moat, G R, 7 feet; the talus of the ſcarp, *x y*, 2 paces; the depth of the moat, R *x*, 16 feet; the width of its channel, T, 15 feet; the talus of the counterſcarp, *a* K, 10 feet; and the banquet of the covered way, at L, 5 feet. Then follows the paliſade at N, and the glacis or eſplanade, M. In *fig.* 12. is repreſented a hexagon fortified with all the kinds of out-works, together with the manner of carrying on the trenches of approach. Here is alſo delineated a pentagonal citadel, with its out-works. The names of the different works and parts of this fortification, are theſe; *a*, *a*, *a*, &c. repreſent the declivity or ſlope, uſually called glacis; *b*, *b*, *b*, &c. the covert way; *c*, *c*, *c*, &c. the counterſcarp; *d*, a ſingle tenaille; *e*, a double tenaille; *f*, a horn-work; *g*, *g*, *g*, &c. places of arms; *h*, *h*, *h*, &c. the moat or ditch; *i*, *i*, *i*, &c. ravelins; *k*, *k*, *k*, &c. half moons; *l*, a crown-work; *m*, a bonnet or prieſt's cap; *n*, *n*, a counter-guard; *o*, *o*, *o*, &c. baſtions; *p*, *p*, *p*, baſtions with circular flanks; *q*, *q*, the curtain; *r*, *r*, *r*, &c. the ramparts; and *s*, *s*, *s*, &c. bridges over the moat. With reſpect to the approaches,

1, 1, 1, &c. repreſent the trenches; 2, 2, 2, &c. the lines of communication; 3, 3, batteries; 4, 4, 4, &c. forts for the defence of the trenches; 5, the deſcent into the covered way; and 6, a mine.

Irregular FORTIFICATIONS, are thoſe raiſed about irregular polygons; in which the engineer ought to follow, as much as poſſible, the proportions laid down for the regular ones. If baſtions are found too high to ſweep the circumjacent champaign, a ſecond baſtion muſt be added to the firſt, or even a third, if neceſſary; ſtill taking care that their faces be well defended. If, on the contrary, a baſtion is too low, a cavalier muſt be raiſed on it. It will ſometimes alſo happen, that the faces of baſtions would become exceſſive long, if they were to be extended till they meet; in which caſe, they are uſually cloſed with a re-entering angle, (*fig.* 13.) When one ſide of the polygon is long enough to admit of a baſtion in its middle, it is remedied by raiſing one; but if it will not admit of this, it may be remedied by forming a ſaliant angle in the middle; or by advancing the neighbouring baſtions nearer to each other, ſo that both may be entirely formed upon that ſide. When a long extended ſide of a place can not admit of baſtions, as being cut off by a river, or ſtands upon a deep aſcent, it may be fortified with redents or re-entering angles, not unlike the teeth of a ſaw. See *fig.* 14. But the defect of theſe redents is, that both the ſides of the tenaille, or front of a place, may be ruined from one battery; ſo that the beſiegers may than make an aſſault without fear of being enfiladed.

Marine FORTIFICATIONS. Though theſe have nothing peculiar in them, yet it may not be improper to give ſome directions with relation to batteries. 1. In raiſing batteries to hinder a deſcent, care ſhould be taken to diſpoſe them in ſuch places where the deſcent is moſt eaſy; and the guns ſhould be ſo levelled, as to ſcour the ſurface of the water, that they may fire effectually upon the boats as they approach. 2. It is likewiſe convenient to have batteries to play upon places where there is good anchorage; and theſe ſhould be ſomewhat more elevated than the former. 3. It is alſo neceſſary to erect batteries at the entrance of roads; and theſe ought to be ſo made, as to diſcover ſhips at a diſtance. 4. It is very neceſſary that theſe batteries ſhould be defended by ſome works, againſt attacks; and, if poſſible, ſhould be under the fire of the place; or, at leaſt, they ought not to be too far advanced.

FORTIN, FORTLET, or *Field* FORT, a ſconce or little fort, whoſe flanked angles are generally diſtant one from another a hundred and twenty fathoms. See FORT.

FORTISSIMO, in muſic, ſometimes denoted by FFF, or *f f f*, ſignifies to ſing or play very loud or ſtrong.

FORTUNE, *Fortuna*, a goddeſs worſhipped with great devotion by the ancient Greeks and Romans, who believed her to preſide over human affairs, and to diſtribute wealth and honour at her pleaſure.

FORUM, in Roman antiquity, a public ſtanding place within the city of Rome, where cauſes were judicially tried, and orations delivered to the people.

FOSS, or FOSSA, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

Foſs is particularly uſed for the cavity, or indenture, in the back part of the neck.

FOSSA MAGNA, the interior cavity, or rima magna, of the pudendum muliebre. Bartholin calls it foſſa navicularis.

FOSS, in fortification, a hollow place, commonly full of water, lying between the ſcarp and counterſcarp, below the rampart; and turning round a fortified place or a poſt that is to be defended. See MOAT.

FOSS-WAY, one of the four principal highways of England, that anciently led through the kingdom; ſuppoſed to be made by the Romans, having a ditch upon one ſide thereof.

FOSIL, in natural hiſtory, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, ſtones, ſalts, earths, and other minerals; or extraneous, repoſited in the bowels of the earth by ſome extraordinary means, as earthquakes, the deluge, &c.

FOVEA CORDIS, in anatomy, the pit of the heart, or rather of the ſtomach.

FOUGADE, or FOUGASSE, in the art of war, a little mine, about eight or ten feet wide; and ten or twelve deep, dug under ſome work or poſt, which is in danger of falling into the enemy's hands; and charged with ſacks of powder, covered with ſtones, earth, and whatever elſe can make great deſtruction. It is ſet on fire like other mines, with a ſauciſſe.

FOUL, in the ſea-language, entangled or embarraſſed: foul anchor, i. e. an anchor which has either hooked its own or ſome other cable, wreck, rocks, &c. "a ſhip ran foul of us in the night," i. e. came cloſe to our ſhip, entangling herſelf amongſt the rigging.

FOUL-BOTTOM is when the bottom of a ſhip is covered with ooze, graſs, ſhells, or other excrement.

FOUL-HAWSE is when the ſhip being moored by two anchors, has turned round, and conſequently twiſted one cable about the other.

FOUL-WIND, a wind which blows contrary to the ſhip's courſe.

FOULNESS, in ſurgery, a term applied to wounds, where the fleſh is putrid, fungous, black, or livid.

FOUNDATION, in architecture, is that part of a building which is under ground. See BUILDING.

Foundation, called by Daviler *fondation*, is the coffer or bed dug below the level of the ground to raiſe a building upon, in which ſenſe the foundation either goes to the whole area of the building, as when there are to be vaults, cellars, &c. or it is drawn in trenches, as when only walls are to be raiſed. The foundation, fondement according to the ſame author, is properly ſo much of the maſonry as reaches as high as the ſurface of the ground, and ought always to be proportioned to the load or weight of the building that it is to bear. Sometimes the foundation is maſſive, and continued under the whole building, as in the antique arches and aqueducts, and ſome amphitheatres; but it is more uſually in ſpaces or intervals, either to avoid expence, as becauſe the vacuities are at too great a diſtance, in which latter caſe they make uſe of inſulated pillars bound together by arches.

Palladio allows a ſixth part of the height of the whole building for the hollowing or under-digging, unleſs there be cellars under-ground, in which caſe he would have it ſomewhat lower; and as to thickneſs, double the width of a wall is no bad rule. Palladio alſo lays down ſeveral rules to know if the earth be firm enough for the foundation, by obſervations from the digging of wells, and the like; but the beſt way to diſcover the nature of the ſoil is to try it with an iron-crow, or elſe with a borer, ſuch as is uſed by well-diggers.

Foundations are either natural or artificial. Natural as when we build upon a rock, or very ſolid earth, in which caſe we need not ſeek for any further ſtrengthening; for theſe, without digging or other artificial helps, are of themſelves fit to uphold the greateſt buildings. But if the ground be ſandy, or marſhy, or hath lately been dug, recourſe muſt be had to art. If the ground be ſandy or marſhy, you muſt dig till you find ſound ground, and the beſt is that which requires moſt labour in cutting, and when wet, does not diſſolve into dirt. If the earth to be built upon is very ſoft, as in mooriſh grounds, lay good pieces of oak, whoſe length muſt be about the breadth of the trench, or two feet longer than the breadth of the wall, acroſs the foundation, about two feet aſunder, and being well rammed down, lay long planks upon them, pinning or ſpiking down each plank to the pieces of oak on which it lies. But if the ground be very bad, let piles of oak, of a diameter about one twelfth part of their length, be drove down to reach the good ground, and placed as cloſe as one can ſtand by another; then ſpike down long planks upon them. And it muſt not be forgot to place the piles not only under the outer walls, but alſo under the inner walls that divide the building; for if theſe ſhould ſink it would make the outer wall crack, and ſo ruin the whole building. If the ground be faulty here and there let arches be turned over the faulty places, which will diſcharge them of the weight. As to the rules neceſſary to be obſerved in the ſubſtruction or artificial part of the foundation, they are theſe, 1. That the bottom of the trench

be made exactly level. 2. That the loweſt ledge or row be all of ſtone (the broader the better) laid cloſe together. 3. That the breadth of the ground-work be at leaſt double that of the wall to be raiſed on it. However, the breadth may be regulated according to the goodneſs of the ground, and the weight of the intended edifice. 4. That the foundation be made to diminiſh as it riſes, taking care, however, that it do ſo equally on both ſides. 5. That you ought never to build on the ruins of an old foundation, unleſs well aſſured of its depth and ſtrength to bear the ſuperſtructure. 6. And laſtly, The ſtones in a foundation ſhould be laid as they naturally lay in the quarry; a precept generally obſerved by all good architects, becauſe they find the ſtones are ſubject to cleave that way of the grain that lay horizontally in the quarry. In ſome places, buildings near the water are founded on ſacks of wool laid like matreſſes, which being well preſſed and greaſy, will never give way, nor rot in the water.

FOUNDATION *of Bridges* is laid after different manners. The firſt is by incloſing all round the ſpace of ground you would build upon, by dams made with piles ſet deep in the ground in double rows, well ſtrengthened and bound together with croſs pieces and cords, and filling the vacant ſpaces between them with chalk or other earthy matter. This being done, the water muſt be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be neceſſary, upon which the walls of the foundation muſt be laid. But this method is only practicable in building on ſuch rivers, where the water is neither very rapid, nor very deep. The ſecond is done by laying the foundation on grate-work, rafts of ſtout oak well bound together, and made faſt at the ſurface of the water with cables or machines, and building upon them large quarters of ſtone, cramped together, and joined with good mortar, or cement, and afterwards letting them deſcend ſoftly by theſe cables and machines perpendicularly to the bottom of the water. This was the method practiſed in laying the foundation of Weſtminſter-Bridge, the grating being made of the bottom of a frame called by the French *caiſſon*, the ſides of which were ſo contrived that they might be taken off, after a pier was finiſhed. The third is by drawing off all, or the greateſt part of the water of the river into ſome other place; and this was done at London-Bridge, if we could believe Stow, who alledges, that during the time of building, the river was turned from Batterſea to Rotherhith: but this is not warranted.

FOUNDATION denotes alſo a donation or legacy either in money or lands, for the maintenance and ſupport of ſome community, hoſpital, ſchool, lecture, &c.

FOUNDAY, in metallurgy, a term uſed by the workers at the iron-mines in many counties of England, for the ſpace of ſix days, in which time they continue to make a determinate quantity of iron; ſo that they count their work by theſe foundays, or weeks.

FOUNDER, in a general ſenſe, the perſon who lays a foundation, or endows a church, ſchool, religious houſe, or other charitable inſtitution. The founder of a church may preſerve to himſelf the right of patronage, or preſentation to the living.

FOUNDER alſo implies an artiſt who caſts metals, in various forms, for different uſes, as guns, bells, ſtatues, printing characters, candleſticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of ſmall works, &c. See FOUNDERY.

FOUNDER, in glaſs-making, a term appropriated to the crown and green glaſs, and is the perſon there, who in the ſame office in the white-glaſs making is called conciator.

FOUNDERING, in the menage, a diſorder in horſes, of which there are two kinds, viz. in the feet and in the cheſt.

Foundering in the feet, is an univerſal rheumatiſm, or defluxion of humours upon the ſinews of a horſe's feet, which cauſes ſo great a ſtiffneſs in the hoofs, that the horſe has no ſenſe or feeling of them.

This diſorder ariſes from hard riding; from great heats and colds; and is ſometimes occaſioned by watering a horſe when he is very hot, by which means, as the farriers term it, his greaſe is melted within him; alſo by wearing too ſtreight a ſhoe, or travelling upon hard ground.

The general methods of curing this diſtemper are, firſt to pare all the horſe's ſoles ſo thin, that you may ſee the quick: then bleed him well at every toe; ſtop the vein with tallow and roſin; and having tacked hollow ſhoes on his feet, ſtop them with bran, tar, and tallow, as boiling hot as may be; and this renew once in two days for a week together, after which, let him have good exerciſe, &c. or, after he is pared thin, and let blood at his toes, ſtop his feet with cow's dung, kitchen-fee, tar, and ſoot, boiled together, and poured boiling-hot into them.

Foundering in the cheſt may proceed from crudities in the ſtomach, or other infirmities, obſtructing the paſſages of the lungs; and may be diſcovered by the horſe's not being able to bow his joints; and being once laid, he cannot riſe again; his legs ſwell, &c.

As a particular remedy for cheſt-foundering, take five or ſix pennyworth of oil of petre, and mingle it with an equal quantity of ale, or beer: then rub this mixture with your hand on the part affected; and cauſe a red-hot fire-ſhovel to be held before it during the application.

FOUNDERING, among ſailors, ſinking in a ſtorm at ſea.

FOUNDERY, or FOUNDRY, the art of caſting all ſorts of metals, into different forms. It likewiſe ſignifies the work-houſe, or ſmelting-hut, wherein theſe operations are performed.

FOUNDERY, or CASTING, among ſculptors, &c. See the article CASTING.

FOUNDERY *of Bells*. The metal, it is to be obſerved, is different for bells, from what it is for ſtatues; there being no tin in the ſtatue-metal; but there is a fifth, and ſometimes more, in the bell-metal. See the article BELL.

The dimenſions of the core, and the wax, for bells, if a ring of bells eſpecially, are not left to chance, but muſt be meaſured by a ſcale, or diapaſon, which gives the height, aperture, and thickneſs neceſſary for the ſeveral tones required. See the article DIAPASON.

It is on the wax that the ſeveral mouldings and other ornaments are formed to be repreſented in relievo, on the outſide of the bell.

The buſineſs of bell-foundery is reducible to three particulars: 1. The proportion of a bell; 2. The forming of the mould; and, 3. The melting of the metal.

The proportions of the Engliſh bells differ much from thoſe of the Chineſe: in the former, the modern proportions are to make the diameter fifteen times the thickneſs of the brim, and twelve times the height.

There are two kinds of proportions, viz. the ſimple and the relative; the former are thoſe proportions only that are between the ſeveral parts of a bell, to render it ſonorous; the relative proportions eſtabliſh a requiſite harmony between ſeveral bells.

The particulars neceſſary for making the mould of a bell, are, 1. The earth: the moſt coheſive is the beſt: it muſt be well ground and ſifted, to prevent any chinks. 2. Brick-ſtone; which muſt be uſed for the mine, mould, or core, and for the furnace. 3. Horſe-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inſcriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a ſlight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a ſcaffold conſiſting of four boards, ranged upon treſſels. Upon this, they carry the earth, groſsly diluted, to mix it with horſe-dung, beating the whole with a large ſpatula.

The compaſſes of conſtruction is the chief inſtrument for making the mould, which conſiſt of two different legs, joined by a third piece. And laſt of all, the founders ſhelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They firſt dig a hole, of a ſufficient depth to contain the mould of the bell, together with the caſe, or cannon,

under-ground; and about ſix inches lower than the terre-plain, where the work is performed. The hole muſt be wide enough for a free paſſage between the mould and walls of the hole; or between one mould and another, when ſeveral bells are to be caſt. At the center of the hole is a ſtake erected, that is ſtrongly faſtened in the ground. This ſupports an iron-peg, on which the pivot of the ſecond branch of the compaſſes turns. The ſtake is encompaſſed with a ſolid brick-work, perfectly round, about half a foot high, and of the propoſed bell's diameter. This they call a mill-ſtone. The parts of the mould are the core, the model of the bell, and the ſhell. When the outer ſurface of the core is formed, they begin to raiſe the core, which is made of bricks that are laid in courſes of equal height upon a lay of plain earth. At the laying each brick they bring near it the branch of the compaſſes, on which the curve of the core is ſhaped, ſo as that there may remain between it and the curve the diſtance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horſe-dung, on which they move the compaſſes of conſtruction, to make it of an even ſmoothneſs every where.

The firſt layer being finiſhed, they put the fire to the core, by filling it half with coals, through an opening that is kept ſhut, during the baking, with a cake of earth, that has been ſeparately baked. The firſt fire conſumes the ſtake, and the fire is left in the core, half or ſometimes a whole day: the firſt layer being thoroughly dry, they cover it with a ſecond, third, and fourth; each being ſmoothed by the board of the compaſſes, and thoroughly dried before they proceed to another.

The core being completed, they take the compaſſes to pieces, with intent to cut off the thickneſs of the model, and the compaſſes are immediately put in their place, to begin a ſecond piece of the mould. It conſiſts of a mixture of earth and hair, applied with the hand on the core, in ſeveral cakes that cloſe together. This work is finiſhed by ſeveral layers of a thinner cement of the ſame matter, ſmoothed by the compaſſes, and thoroughly dried, before another is laid on. The firſt layer of the model is a mixture of wax and greaſe ſpread over the whole. After which are applied the inſcriptions, coats of arms, &c. beſmeared with a pencil dipped in a veſſel of wax in a chaffing-diſh: this is done for every letter. Before the ſhell is begun, the compaſſes are taken to pieces, to cut off all the wood that fills the place of the thickneſs to be given to the ſhell.

The firſt layer is the ſame earth with the reſt, ſifted very fine; whilſt it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model that fills exactly all the ſinuoſities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a ſecond of the ſame matter, but ſomething thicker: when this ſecond layer becomes of ſome conſiſtence, they apply the compaſſes again, and light a fire in the core, ſo as to melt off the wax of the inſcriptions, &c.

After this, they go on with other layers of the ſhell, by means of the compaſſes. Here they add to the cow's hair a quantity of hemp, ſpread upon the layers, and afterwards ſmoothed by the board of the compaſſes. The thickneſs of the ſhell comes to four or five inches lower than the mill-ſtone before obſerved, and ſurrounds it quite cloſe, which prevents the extravaſation of the metal. The wax ſhould be taken out before the melting of the metal.

The ear of the bell requires a ſeparate work, which is done during the drying of the ſeveral incruſtations of the cement. It has ſeven rings, the ſeventh is called the bridge, and unites the others, being a perpendicular ſupport to ſtrengthen the curves. It has an aperture at the top, to admit a large iron-peg, bent at the bottom; and this is introduced into two holes in the beam, faſtened with two ſtrong iron-keys. There are models made of the rings, with maſſes of beaten earth, that are dried in the fire, in order to have the hollow of them. Theſe rings are gently preſſed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half moulds, that two and two united may make the hollows of the ſix rings: the ſame they do for the hollow of the bridge, and brake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that conſtitute the ear. They firſt put into this open place the iron-ring to ſupport the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickneſs of the core. This cake, after baking, is clapped upon the opening, and ſodered with a thin mortar ſpread over it, which binds the cover cloſe to the core.

The hollow of the model is filled with an earth, ſufficiently moiſt, to fix on the place, which is ſtrewed, at ſeveral times, upon the cover of the core; and they beat it gently with a peſtle, to a proper height; and a workman ſmooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they aſſemble the hollows of the rings. When every thing is in its proper place, they ſtrengthen the outſides of the hollows with mortar, in order to bind them with the bridge, and keep them ſteady at the bottom, by means of a cake of the ſame mortar, which fills up the whole aperture of the ſhell: this they let dry, that it may be removed without breaking. To make room for the metal they pull off the hollows of the rings, through which the metal is to paſs, before it enters into the vacuity of the mould. The ſhell being unloaded of its ear, they range under the mill-ſtone five or ſix pieces of wood, about two feet long, and thick enough to reach almoſt the lower part of the ſhell; between theſe and the mould they drive in wooden wedges with a mallet, to ſhake the ſhell of the model whereon it reſts, ſo as to be pulled up, and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal muſt run, from the hollow of the rings, between the ſhell and the core. They ſmoke the inſide of the ſhell, by burning ſtraw under it, that helps to ſmooth the ſurface of the bell: then they put the ſhell in the place, ſo as to leave the ſame interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a maſs of baked cement: after which they put on this maſs of the cap, the rings, and the vent, over the ſhell, and ſoder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it ſtrongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a ſpacious aſh-hole. The furnace which contains the metal, is vaulted, whoſe bottom is made of earth, rammed down; the reſt is built with brick. It has four apertures; the firſt, through which the flame reverberates; the ſecond is cloſed with a ſtopple that is opened for the metal to run; the others are to ſeparate the droſs, or ſcoriæ, of the metal by wooden rakes: through theſe laſt apertures paſſes the thick ſmoke. The ground of the furnace is built ſloping for the metal to run down.

FOUNDERY *of great Guns and Mortar-Pieces.*—The method of caſting theſe pieces is little different from that of bells: they are run maſſy, without any core, being determined by the hollow of the ſhell; and they are afterwards bored with a ſteel trepan, that is worked either by horſes, or a water-mill.

For the metal, parts, proportions, &c. of theſe pieces. See CANNON.

Letter FOUNDERY, or *Caſting of Printing-Letters.* The firſt thing requiſite is to prepare good ſteel-punches, on the face of which is drawn the exact ſhape of the letter with pen and ink, if the letter be large, or with a ſmooth blunted point of a needle, if ſmall; and then, with proper gravers, the cutter digs deep between the ſtrokes, letting the marks ſtand on the punch; the work of hollowing being generally regulated by the depth of the counter-punch: then he files the outſide, till it is fit for the matrice.

They have a mould to juſtify the matrices by, which

conſiſts of an upper and under part, both which are alike, except the ſtool and ſpring behind, and a ſmall roundiſh wire in the upper part, for making the nick in the ſhank of the letter. Theſe two parts are exactly fitted into each other, being a male and female gage, to ſlide backwards and forwards. See the article GAGE.

Then they juſtify the mould, by caſting about twenty ſamples of letters, which are ſet in a compoſing-ſtick, with the nicks towards the right hand; and comparing theſe every way with the pattern-letters, ſet up in the ſame manner, they find the exact meaſure of the body to be caſt.

Next they prepare the matrix, which is of braſs or copper, an inch and a half long, and of a proportionable thickneſs to the ſize of the letter it is to contain. In this metal is ſunk the face of the letter, by ſtriking the letter-punch the depth of an *n*. After this, the ſides and face of the matrice are juſtified, and cleared, with files, of all bunchings that have been made by ſinking the punch.

Then it is brought to the furnace, which is built upright of brick with four ſquare ſides, and a ſtone at top, in which is a hole for the pan to ſtand in. They have ſeveral of theſe furnaces. See the article FURNACE.

Printing-letters are made of lead, hardened with iron or ſtub-nails. To make the iron run, they mingle an equal weight of antimony, beaten ſmall in an iron mortar, and ſtub-nails together. They charge a proper number of earthen pots, that bear the fire, with the two ingredients, as full as they can hold, and melt it in an open furnace, built for that purpoſe. See the article FLUX.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compoſt is ladled into an iron-pot, wherein is melted lead, that is fixed on a furnace cloſe to the former, 3 lb. of melted iron to 25 lb. of lead; this they incorporate according to art.

The caſter taking the pan off the ſtone, and having kindled a good fire, he ſets the pan in again, and metal in it to melt. If it be a ſmall bodied letter, or a thin letter with great bodies, that he intends to caſt, his metal muſt be very hot, and ſometimes red hot, to make the letter come. Then taking a ladle, of which he has ſeveral ſorts, that will hold as much as will make the letter and break, he lays it at the hole where the flame burſts out; then he ties a thin leather, cut with its narrow end againſt the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and faſtening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice cheek; and places the foot of the matrice on the ſtool of the mould, and the broad end of the leather on the wood of the upper haft of the mould, but not tight up, leſt it hinder the foot of the matrice from ſinking cloſe down upon the ſtool, in a train of work. Afterwards laying a little roſin on the upper part of the mould, and having his caſting-ladle hot, he, with the boiling ſide, melts the roſin and preſſes the broad end of the leather hard down on the wood, and ſo faſtens it thereto. Now he comes to caſting, when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the lower part of the ball of his thumb and his three hinder fingers; then he lays the upper half of the mould upon the under half, ſo as the male gages may fall into the female; and, at the ſame time, the foot of the matrice places itſelf upon the ſtool, and claſping his left hand thumb ſtrongly over the upper half, he nimbly catches hold of the bow or ſpring, with his right hand fingers at the top of it, and his thumb under it, and places the point of it againſt the middle of the notch in the backſide of the matrice, preſſing it forwards as well towards the mould, as downwards, by the ſhoulder of the notch, cloſe upon the ſtool, while at the ſame time with his hinder fingers, as aforeſaid, he draws the under half of the mould towards the ball of his thumb, and thruſts, by the ball of his thumb, the upper part towards his fingers, that both the regiſters of the mould may preſs againſt both ſides of the matrice, and his thumb and fingers preſs both ſides of the mould cloſe together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three ſtrokes outwards upon the ſurface of the melted metal, to clear it of the ſcum; then he takes up the ladle full, and having the mould in the left hand, turns his left ſide a little from the furnace, and brings the geat of his ladle to the mouth of the mould; and turns the upper part of his right hand towards him, to pour the metal into it, while, at the ſame inſtant, he puts the mould in his left hand forwards, to receive the metal with a ſtrong ſhake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the ſhank. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he toſſes the letter, break and all, out upon a ſheet of waſte paper, laid on a bench, a little beyond his left hand; and then is ready to caſt another letter, as before, and likewiſe the whole number in that matrix.

Then boys, commonly employed for this purpoſe, ſeparate the breaks from the ſhanks, and rub them on a ſtone, and afterwards a man cuts them all of an even height, which finiſhes the fount for the uſe of the printer. See the next article.

A workman will ordinarily caſt 3000 of theſe letters in a day. The perfection of letters thus caſt, conſiſts in their being all ſeverally ſquare and ſtraight on every ſide; and all generally of the ſame height, and evenly lined, without ſtooping one way or other; neither too big in the foot, nor the head; well grooved, ſo as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and ſcraped, with a ſenſible notch, &c. See the article PRINTING.

FOUNT, or FONT, among printers, a ſet or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. caſt by a letter-founder, and ſorted. Founts are large or ſmall, according to the demand of the printer, who orders them by the hundred weight, or by ſheets. When a printer orders a fount of five hundred, he means that the fount, conſiſting of letters, points, ſpaces, quadrates, &c. ſhall weigh 500 lb. When he demands a fount of ten ſheets, it is underſtood, that with that fount he ſhall be able to compoſe ten ſheets, or twenty forms, without being obliged to diſtribute. The founder takes his meaſures accordingly; he reckons 120 lb. for a ſheet, including the quadrates, &c. or 60 lb. for a form, which is only half a ſheet; not that the ſheet always weighs 120 lb. or the form 60 lb. on the contrary, it varies according to the ſize of the form; beſides, it is always ſuppoſed that there are letters left in the caſes. As therefore every ſheet does not comprehend the ſame number of letters, nor the ſame ſort of letters, we muſt obſerve, that, as in every language ſome ſounds recur more frequently than others, ſome letters will be in much more uſe, and oftener repeated than others, and conſequently their cells or caſes ſhould be better ſtored than thoſe of the letters which do not recur ſo frequently: thus, a fount does not contain an equal number of *a* and *b*, or of *b* and *c*, &c. the letter-founders have therefore a liſt or tariff, or, as the French call it, a *police*, by which they regulate the proportions between the different ſorts of characters that compoſe a fount; and it is evident that this tariff will vary in different languages, but will remain the ſame for all ſorts of characters employed in the ſame language.

FOUNTAIN, *Fons*, a ſpring of living water that riſes out of the ground. See SPRING.

Fountains or ſources of rivers were held ſacred among the ancients, and even worſhipped as a kind of divinity: and it was a point of religion, not to muddy the waters in bathing.

Artificial FOUNTAIN, or *jet d'eau*, a contrivance, whereby water is violently ſpouted upwards.

Some fountains are founded on the elaſticity of the air, and others on the preſſure of the water.

The artificial fountain (plate LXVI. *fig.* 1.) which may be ſet up upon either of its ends, after it has played out all its water in a jet through the ſpouting-pipe E, plays again afreſh through the ſpout I, when you have turned it over like an hour-glaſs. The water contained in the cavity AFH runs down the curve pipe CDE, and ſpouts up through the jet E by the preſſure of the column of water CD. But, unleſs the pipe GF was

open

open at G; to let the air run up to F, and preſs at top of the ſurface of the water in the cavity A, the water could not run down and ſpout at E. There is ſuch another pipe as G F at K, belonging to the cavity B, through which the water of the jet received in the baſon ſupplies the cavity B, whilſt the fountain ſtands on the end B: but, when the fountain is inverted, it ſupplies B with air to let the water deſcend in the direction G H I, I becoming the ſpouting pipe.

Upon theſe principles depends alſo the alternate running and ſtopping of the fountain at command (*fig.* 2.) C A E is a receptacle of water cloſe from the air's entrance, except through the pipe G F, when the cock C, by which it was filled, is ſtopped. There is another pipe E D H B, which goes from the bottom of the water to the jet B in the baſon D B, but is ſtopped by the cock H. At the loweſt part of the baſon D B there is a ſmall hole at I to let the water of the baſon D B run into the baſon G H under it: there is alſo a ſmall triangular hole or notch in the bottom of the pipe F G at G. Turn the cock H, and the fountain will play ſome time; then ſtop, then play again alternately. The cauſe of playing and ſtopping is this; the water coming down the pipe E D H B would not come out at B, if the air S *s* above the water were not ſupplied, as it dilated: now it is ſupplied by the pipe G F, which takes it in at the notch G, and delivers it out at F; but after ſome time the water which has ſpouted out at B, falling down into the baſon D B, riſes high enough to come above the notch G, which ſtops the paſſage of the air, ſo that the air S *s* above the water in the veſſel C A E cannot ſufficiently preſs for want of a ſupply, and the fountain ceaſes playing. Now the water of D B runs down into the lower baſon H G, through the hole I, till it falls below the top of the notch G, and then the air runs up into the upper receptacle again, and ſupplying the air at S *s*, the fountain plays again. This is ſeen a little before-hand by a ſkin of water on the notch G, before the air finds paſſage, and then you command the fountain to play. The hole I muſt be leſs than that of the jet, otherwiſe the water would all run out into the lower baſon, without riſing high enough to ſtop the notch G.

In the next fountain A B (*fig.* 3.) the air is condenſed at the top of the water by means of a ſyringe, ſometimes by blowing in; and the air and water are retained by the cock C, which muſt be opened, before it can play; then the water, ſtrongly preſſed by the condenſed air at S S, goes through the pipe *o* and the adjutage *b* with great force, in jets of ſeveral figures according to the ſpouting-pipes put on at *b*.

In the fountain (*fig.* 4.) the air, being compreſſed by the concealed fall of waters, makes a jet, which ſeen for a while is looked upon as a perpetual motion by the ignorant.

The boxes C E and D Y X being cloſe, you only ſee the baſon A B W, with a hole at W, into which the water ſpouting out at B falls; but that water, going down the hole W, does not come up again at W, but runs down through the pipe W X into the box D Y X, from whence it drives out the air through the aſcending pipe Y Z into the cavity of the box C E, where, preſſing upon the water that is in it, it forces it out through the ſpouting-pipe O B, as long as there is any water in C E: ſo that this whole play is only whilſt the water contained in C E, having ſpouted out, falls down through the pipe W X into the cavity D Y X. The force of the jet is proportional to the height of the pipe W X, or of the boxes C E and D Y X above each other. The height of the water, meaſured from the baſon A B W to the ſurface of the water in the lower box D Y X, is always equal to the height meaſured from the top of the jet to the ſurface of the water in the middle cavity at C E. Now ſince the ſurface C E is always falling, and the water in D Y always riſing, the height of the jet muſt continually decreaſe, till it is ſhorter by the height of the depth of the cavity C E, which is emptying, added to the depth of the cavity D Y, which is always filling; and, when the jet is fallen ſo low, it immediately gives over. In the figure the air is repreſented by points.

To prepare this fountain, which is generally done privately firſt, pour in water at W, till the cavity D X Y be full; then turn the fountain over, and the water will run from the cavity D X Y into the cavity C E, which is full, when the water runs out at B held down. Set the fountain up again as if nothing had been done to it. When you would make it play, pour in about a pint of water into the baſon A B W, and when the pipe W X is filled, the fountain will play, and continue ſo to do, as long as there is water in C E. You may pour the water left in the baſon A B W into any veſſel, and invert the fountain, which, when ſet upright, will be ſet a playing by putting back the water poured out into A B W, and ſo toties quoties.

FOURCHEE, or FOURCHY, in heraldry, an appellation given to a croſs forked at the ends.

FOURCHER, or FOURCHING, in law, ſignifies the delaying or putting off an action, which might have been brought to a determination in a ſhorter time.

FOURTH, in muſic, one of the harmonic intervals. It conſiſts in the mixture of two ſounds, which are in the ratio of 4 to 3; that is, of ſounds produced by chords, whoſe lengths are to each other as 4 to 3.

FOWL, among zoologiſts, denotes the larger ſort of birds, whether domeſtic or wild: ſuch are geeſe, pheaſants, partridges, turkies, ducks, &c. See the articles GEESE, PHEASANT, &c.

Tame fowl make a neceſſary part of the ſtock of a country farm. See the article POULTRY.

FOX, *Vulpes*, in zoology, an animal of the dog-kind, which much reſembles the common dog in form, and is of the ſize of a ſpaniel: it is chiefly diſtinguiſhed by its long and ſtraight tail, with the tip white. See the articles CANIS and DOG.

The fox is a native of moſt northern countries. That of Siberia is about the ſize of a common kind; but its head is larger, and its tail not only bigger and more buſhy, but all of one colour.

FOX-GLOVE, *Digitalis*, in botany. See DIGITALIS.

FRACHES, in glaſs-making, flat iron pans, wherein the new-made veſſels are put, to be removed gradually from the fire. See the article GLASS.

FRACTION, in arithmetic, a broken number, a part, or diviſion of an unit, or integer.

The word is Latin, *fractio*, and derived from *frango*, to break.

Fractions are generally divided into *vulgar*, *decimal*, and *ſexageſimal*.

Vulgar FRACTIONS are thoſe which repreſent the parts of any thing propoſed.

A vulgar fraction is expreſſed by two numbers placed one above the other, having a line drawn between them. Thus $\frac{3}{4}$, $\frac{1}{6}$, $\frac{5}{4}$, &c. are vulgar fractions.

The number placed below the line is called the denominator, and denotes how many equal parts the thing is ſuppoſed to be divided into, being only the diviſor in diviſion. And the number placed above the line is called the numerator, and ſhews how many of theſe parts are contained in the fraction, it being the remainder after diviſion. Theſe admit of three diſtinctions, viz. *proper* or *ſimple*, *improper*, and *compound* fractions.

A proper, *pure*, or *ſimple* FRACTION is that which is leſs than an unit: that is, it repreſents the immediate part or parts of any thing leſs than the whole, and therefore its numerator is always leſs than the denominator. As $\frac{1}{3}$, $\frac{1}{4}$, $\frac{3}{5}$, $\frac{5}{6}$, &c.

An improper FRACTION is that which is greater than an unit; that is, it repreſents ſome number of parts greater than the whole thing, and its numerator is always greater than the denominator. As $\frac{5}{3}$, $\frac{9}{7}$, $\frac{41}{13}$, &c.

A compound FRACTION is a part of a part, conſiſting of ſeveral numerators and denominators united together with the word *of*. As $\frac{1}{3}$ of $\frac{3}{4}$ of $\frac{2}{5}$, &c. and is thus read one third of three fourths of two fifths of an unit.

That is, when an unit, or whole thing, is firſt divided into any number of equal parts, and each of theſe parts is ſubdivided into other parts, and ſo on: then theſe laſt parts are called compound fractions, or fractions of fractions.

All compound fractions are reduced to ſingle ones, by the following

Rule.—Multiply all the numerators into one another for a numerator, and all the denominators into one another for the denominator.

Thus

Fig. 1. Fountain.

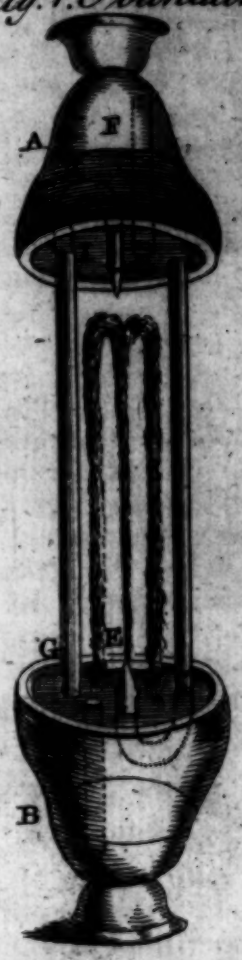

Fig. 2.

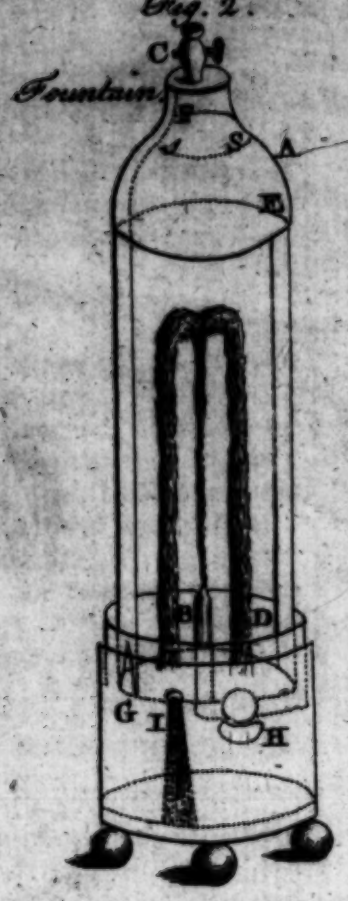

Fig. 3.

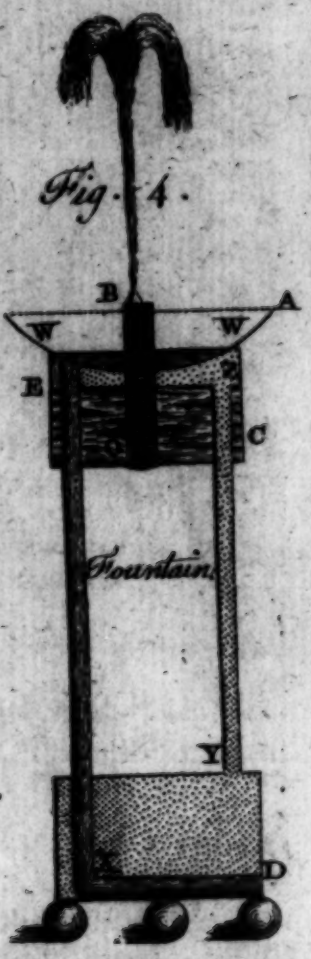
Fig. 4.



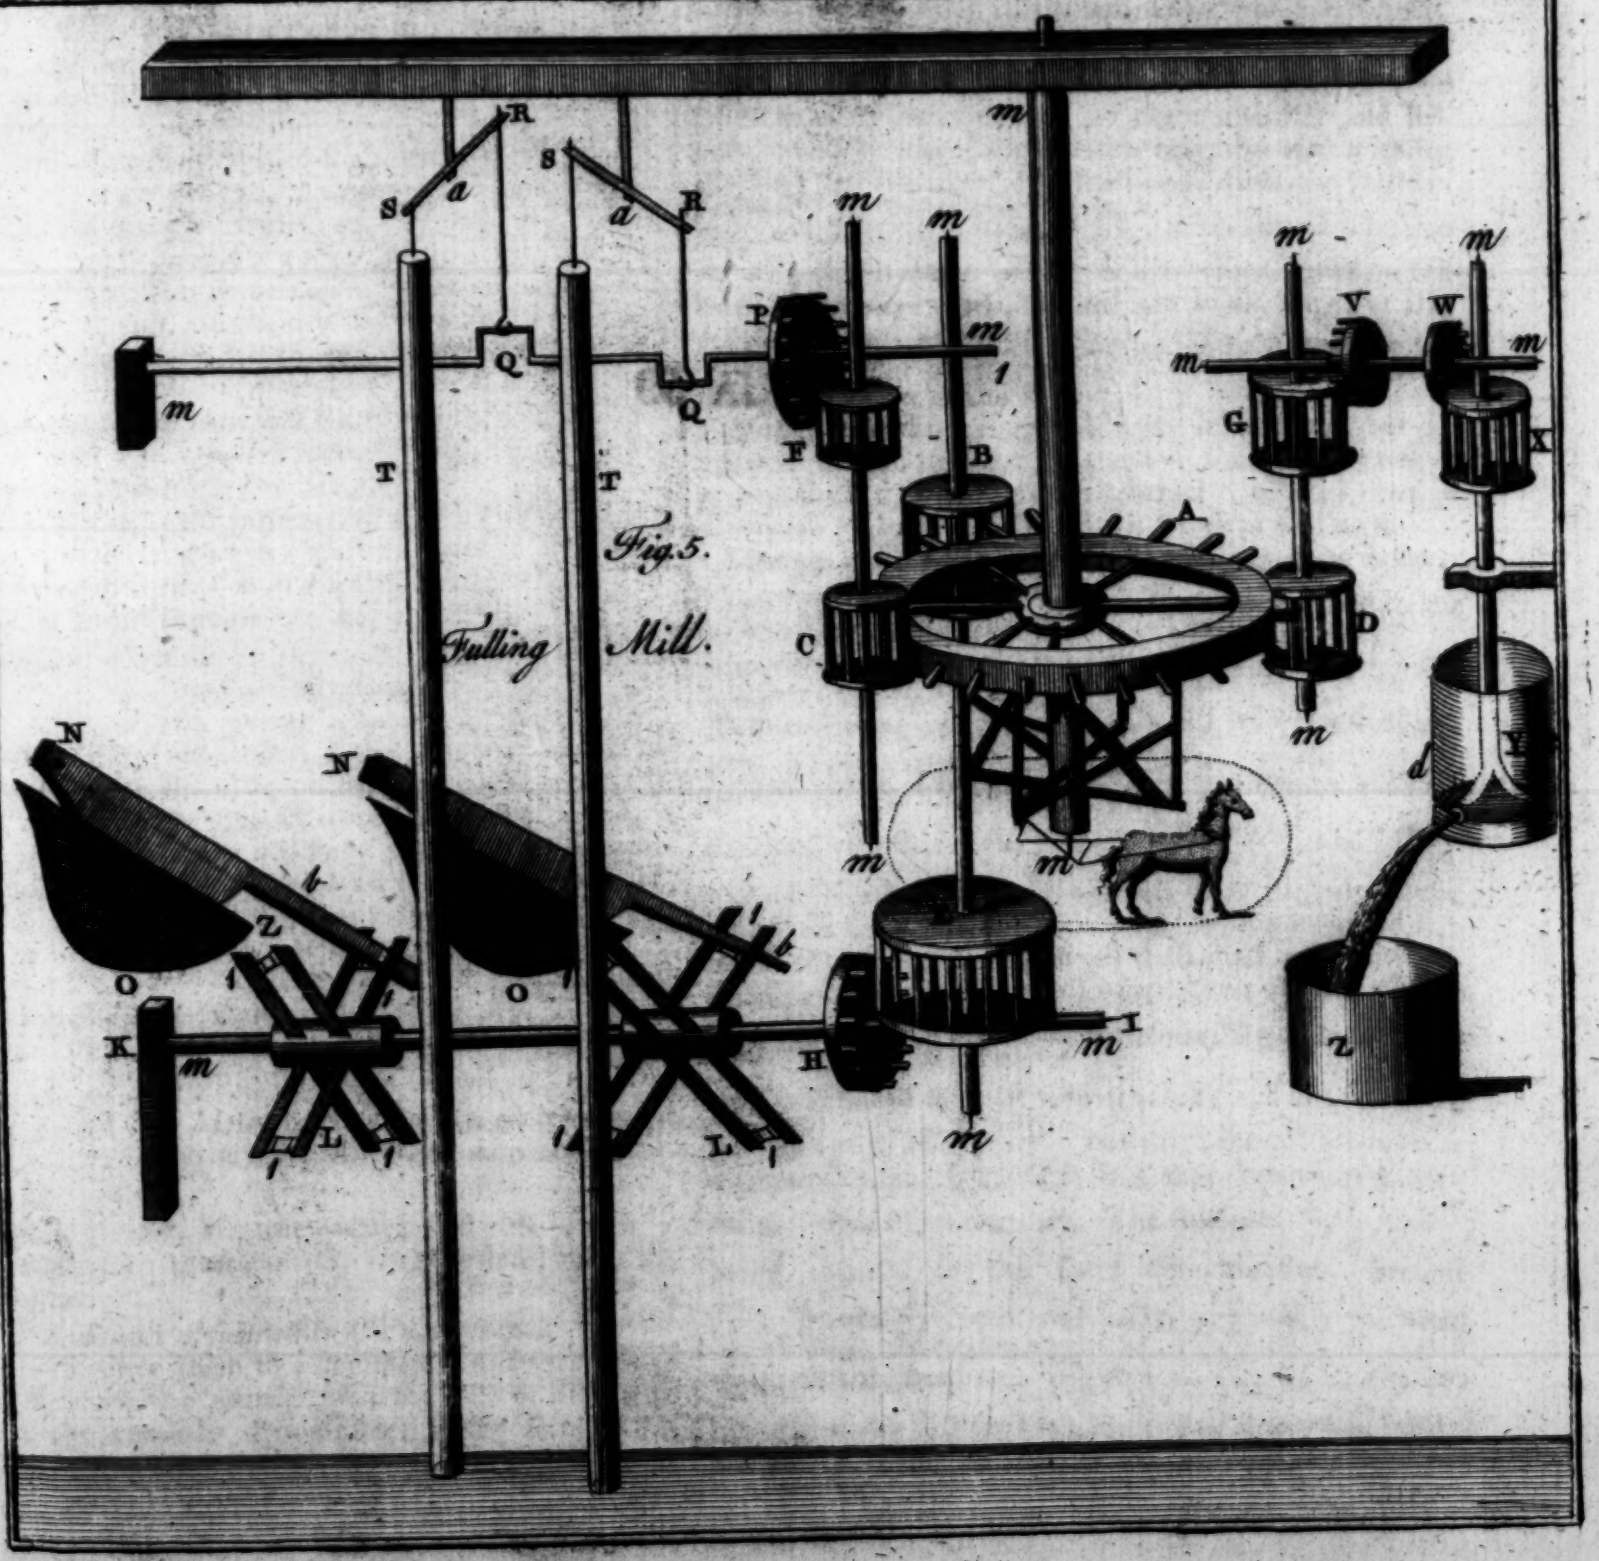


Fig. 5.

Fulling Mill.

5 JA 59

Thus the $\frac{1}{3}$ of $\frac{3}{4}$ of $\frac{2}{5}$ will become $\frac{6}{60}$, or $\frac{1}{10}$.

For $1\times3\times2=6$, the numerator, and $3\times4\times5=60$, the denominator.

To alter or change different FRACTIONS *into one denomination retaining the ſame value.*—In order to gain a clear underſtanding of this propoſition, it will be convenient to premiſe this lemma, viz. If a number multiplying two numbers produce other numbers, the numbers produced of them ſhall be in the ſame proportion that the numbers multiplied are.

That is, if both the numerator and denominator of any fraction be equally multiplied into another number, their products will retain the ſame value with that fraction.

As in theſe $\frac{2}{3}\times\frac{2}{2}=\frac{4}{6}$. Or $\frac{2}{3}\times\frac{3}{3}=\frac{6}{9}$. Or $\frac{2}{3}\times\frac{5}{5}=\frac{10}{15}$, &c.

That is, $\frac{2}{3}$ and $\frac{4}{6}$, or $\frac{2}{3}$ and $\frac{6}{9}$, or $\frac{2}{3}$ and $\frac{10}{15}$, are of the ſame value in reſpect to the whole or unit.

From hence it will be eaſy to conceive, how two or more fractions, that are of different denominations, may be altered or changed into others that ſhall have one common denominator, and ſtill retain the ſame value.

Example.—Let it be required to change $\frac{2}{3}$ and $\frac{3}{7}$ into two other fractions that ſhall have one common denominator, and yet retain the ſame value.

According to the foregoing lemma, if $\frac{2}{3}$ be equally multiplied by 7, it will become $\frac{14}{21}$, viz. $\frac{2}{3}\times\frac{7}{7}=\frac{14}{21}$. Again, if $\frac{3}{7}$ be multiplied equally with 3, it will become $\frac{9}{21}$, viz. $\frac{3}{7}\times\frac{3}{3}=\frac{9}{21}$. And by this means we have obtained two new fractions, $\frac{14}{21}$ and $\frac{9}{21}$, that are of one denomination, and the ſame value with the two firſt propoſed, viz. $\frac{14}{21}=\frac{2}{3}$, and $\frac{9}{21}=\frac{3}{7}$. And from hence ariſes the general rule for bringing all fractions into one denomination.

Rule.—Multiply all the denominators into each other for a new and common denominator; and each numerator into all the denominators except its own, for new numerators.

Example.—Let the propoſed fractions be $\frac{1}{3}$, $\frac{2}{5}$, $\frac{3}{4}$ and $\frac{6}{7}$.

Then $3\times5\times4\times7=420$, the new and common denominator: alſo $1\times5\times4\times7=140$, $2\times3\times4\times7=168$, $3\times3\times5\times7=315$, and $6\times3\times5\times4=360$, the new numerators. Hence 420 is the common denominator; and 140, 168, 315, 360, are the new numerators; and, conſequently, $\frac{140}{420}$, $\frac{168}{420}$, $\frac{315}{420}$, $\frac{360}{420}$, are the new fractions required.

To bring mixed numbers into FRACTIONS, *and the contrary.*—Mixed numbers are brought into improper fractions by the following

Rule.—Multiply the integers, or whole numbers, with the denominator of the given fraction, and to their product add the numerator of the fraction required.

Thus, $9\frac{4}{5}$ will become $\frac{49}{5}$; and $7\frac{6}{7}=\frac{54}{7}$.

To abbreviate or reduce FRACTIONS *into their loweſt or leaſt denomination.*

Rule.—Divide the greater number by the leſſer, and that diviſor by the remainder, if there be any, and ſo on continually, until there be no remainder left: then will the laſt diviſor be the greateſt common meaſure; and, if it happen to be 1, then are thoſe numbers prime numbers, and are already in their loweſt terms; but, if otherwiſe, divide the numbers by that laſt diviſor, and their quotients will be their leaſt terms required.

Example.—Let it be required to find the greateſt common meaſure of 72 and 108, viz. of $\frac{72}{108}$.

```
72) 108 (1
    72
    ---
36) 72 (2     Here, becauſe there is no remainder,
    72        36 is the greateſt common meaſure.
    ---
    (0)
```

Then $72\div36=2$, the numerator; and $108\div36=3$, the denominator: therefore $\frac{72}{108}$ is abbreviated to $\frac{2}{3}$, the loweſt terms.

Addition and ſubtraction of FRACTIONS.

Rule.—Reduce them to a common denominator, and add or ſubtract the numerators; the ſum or difference ſet over the common denominator is the ſum or remainder required.

Thus, $\frac{2}{3}+\frac{3}{4}=\frac{8+9}{12}=\frac{17}{12}=1\frac{5}{12}$; $\frac{3}{4}-\frac{2}{3}=\frac{9-8}{12}=\frac{1}{12}$; $\frac{4}{5}-\frac{3}{4}=\frac{16-15}{20}=\frac{1}{20}$.

Multiplication of FRACTIONS.

Rule.—Multiply their numerators one into another to obtain the numerator of the product; and their denominators multiplied into one another ſhall give the denominator of the product.

Thus, $\frac{2}{3}\times\frac{4}{5}=\frac{8}{15}$.

If a mixed quantity is to be multiplied, firſt reduce it to the form of a fraction, and if any integer is to be multiplied by a fraction, you may reduce it to the form of a fraction by placing an unit under it.

Examples. $5\frac{2}{3}\times\frac{3}{4}=\frac{17}{3}\times\frac{3}{4}=\frac{51}{12}$; $9\times\frac{2}{3}=\frac{9}{1}\times\frac{2}{3}=\frac{18}{3}=6$.

Diviſion of FRACTIONS.

Rule.—Multiply the numerator of the dividend by the denominator of the diviſor, and their product ſhall give the numerator of the quotient: then multiply the denominator of the dividend by the numerator of the diviſor, and their product ſhall give the denominator.

Thus, $\frac{4}{5})\frac{2}{3}(\frac{10}{12}$ $\frac{3}{4})\frac{5}{8}(\frac{32}{24}$.

The ſeveral rules of FRACTIONS *exemplified in algebraic quantities.*

Fractions in algebra are treated juſt in the ſame manner as in common arithmetic, only uſing algebraical inſtead of numeral operations; as will plainly appear from the following examples.

Examples of the reduction of FRACTIONS *from higher to lower terms.*

The fraction $\frac{4ab}{6bc}$, dividing both the numerator and denominator by the ſame quantity $2b$, will be reduced to the fraction $\frac{2a}{3c}$, a fraction of the ſame value with the former, but expreſſed in more ſimple terms: whence we may infer, that whenever a common letter or factor is to be found in every member both of the numerator and denominator, it may be cancelled every-where, without affecting the value of the fractions: thus the fraction $\frac{ac+bc}{cd+ce}$, expunging c, becomes $\frac{a+b}{d+e}$, a fraction of the ſame value. But if there be any one member, wherein the factor is not concerned, it muſt not be expunged at all: thus the fraction $\frac{ac+bc}{cd+e}$ cannot be reduced, becauſe the factor c is not to be found in e.

Note, That cancelling here is not ſubtracting, but dividing: thus to cancel the letter b in the quantity ab, ſo as to reduce it to a, is not to ſubtract b from ab, but to divide ab by b, in which caſe the quotient will be a.

Examples of FRACTIONS *reduced to the ſame denomination.*

1ſt. The fractions $\frac{a}{2}$, $\frac{b}{3}$, and $\frac{c}{4}$, when reduced to the ſame denomination, will ſtand thus; $\frac{12a}{24}$, $\frac{8b}{24}$, and $\frac{6c}{24}$. 2d. The fractions $\frac{a}{b}$ and $\frac{c}{d}$, ſo reduced, will ſtand thus; $\frac{ad}{bd}$ and $\frac{bc}{bd}$. 3. The fractions $\frac{p}{q}$, $\frac{r}{s}$, $\frac{t}{u}$, and $\frac{x}{y}$, after reduction, will ſtand thus; $\frac{psuy}{qsuy}$, $\frac{qruy}{qsuy}$, $\frac{qsty}{qsuy}$, and $\frac{qsux}{qsuy}$.

And here I cannot but obſerve, that the rule of this reduction demonſtrates itſelf: for in this example it is impoſſible not to ſee, that all theſe fractions, notwithſtanding this reduction, ſtill retain their former values: thus the firſt fraction $\frac{psuy}{qsuy}$, by cancelling common factors, is reduced to $\frac{p}{q}$, its former value; and the ſame may be obſerved of all the reſt: and this example amounts to a demonſtration, becauſe it is comprehended in general terms. But to go on: 4th. The fractions $\frac{1}{a}$, $\frac{1}{b}$, and $\frac{1}{c}$, being reduced to the ſame denomination, become $\frac{bc}{abc}$, $\frac{ac}{abc}$, and $\frac{ab}{abc}$. 5th. and laſtly, $\frac{1}{a+b}$ and $\frac{1}{a-b}$, when thus reduced, become $\frac{a-b}{aa-bb}$ and $\frac{a+b}{aa-bb}$: for 1, the numerator of the firſt fraction, multiplied into $a-b$, the denominator of the ſecond, makes $a-b$; and 1, the numerator

merator of the ſecond fraction, multiplied into $a+b$, the denominator of the firſt, makes $a+b$; and the product of the two denominators $a+b$ and $a-b$, multiplied together is $aa-bb$.

Addition of FRACTIONS.

1ſt. Theſe fractions $\frac{a}{2}$, $\frac{b}{2}$, and $\frac{c}{2}$, when added together, make $\frac{a+b-c}{2}$.

2d. The fraction $\frac{a+b}{2}$, added to the fraction $\frac{a-b}{2}$ makes $\frac{2a}{2}$ or a.

3d. The fraction $\frac{a}{b}$, added to the fraction $\frac{c}{d}$, makes $\frac{ad+bc}{bd}$.

4th. a added to $\frac{b}{c}$, that is, $\frac{a}{1}$, added to $\frac{b}{c}$, makes $\frac{ac+b}{c}$.

5th. $\frac{1}{a}$ added to $-\frac{1}{b}$, makes $\frac{b-a}{ab}$.

Subtraction of FRACTIONS.

When fractions are to be ſubtracted, change the ſign of the fraction to be ſubtracted, and then proceed exactly as in addition of fractions. Thus let it be required to ſubtract $\frac{a}{b}$ from $\frac{c}{d}$; by changing the ſign of $\frac{a}{b}$ the quantity to be ſubtracted, we ſhall have $\frac{c}{d}-\frac{a}{b}$ for the required difference, or $\frac{cb-da}{db}$. From $\frac{b}{c}$ ſubtract a, there will remain $\frac{b}{c}-\frac{a}{1}$ or $\frac{b-ca}{c}$. In the ſame manner, if from $\frac{d}{b}$ we take $\frac{a-b}{d}$, there will remain $\frac{d}{b}+\frac{b-a}{d}$ or $\frac{dd+bb-ba}{bd}$.

Multiplication of FRACTIONS.

The multiplication of fractions is performed, by multiplying the numerator and denominator of the multiplicand into the numerator and denominator of the multiplicator reſpectively.

Thus, $\frac{p}{q}\times\frac{r}{s}=\frac{pr}{qs}$, and $\frac{3p}{4q}\times\frac{5q}{6r}=\frac{15pq}{24qr}$ or $\frac{5q}{8r}$.

Diviſion of FRACTIONS.

Diviſion of fractions is performed by multiplying the numerator of the dividend into the denominator of the diviſor, for the numerator of the quotient, and the denominator of the dividend into the numerator of the diviſor for the denominator of the quotient. Or invert the numerator and denominator of the diviſor, and proceed as in multiplication of fractions, the product thence ariſing will be the quotient of the propoſed diviſion.

Let it be required to divide $\frac{p}{q}$ by $\frac{r}{s}$, the quotient by the firſt method becomes $\frac{ps}{rq}$, and by the ſecond, we are to multiply $\frac{p}{q}$ by $\frac{s}{r}$ (the diviſor inverted), which alſo gives $\frac{ps}{qr}$.

It being very uſeful to approximate, by means of a vulgar fraction, any decimal one propoſed, we ſhall here ſhew the method of inveſtigation. In order to this, let $\frac{a}{b}$ and $\frac{c}{d}$ be aſſumed to denote two vulgar fractions, in the loweſt numbers, equal nearly to the firſt figures of the given decimal; the one of them greater, and the other leſs, than the ſaid decimal. Moreover, ſuppoſing $\frac{c}{d}$ to be the neareſt value of the two, and the given quantity (or decimal) to be denoted by q; let there be aſſumed $\frac{a+cx}{b+dx}=q$. Whence x will be had $=\frac{bq-a}{c-dq}=\frac{a-bq}{dq-c}$. Let this value of x be found in the neareſt whole numbers; by means whereof the value of the fraction $\frac{a+cx}{b+dx}$ (which is a firſt approximation to the value p) will be given; and if with the fraction thus determined, and one of the two preceding ones ($\frac{a}{b}$ or $\frac{c}{d}$), the operation be repeated, a new value of x will be had from the very equation above exhibited; and from thence a ſecond approximation or value of the aſſumed fraction $\frac{a+cx}{b+dx}$. Whence the operation (if neceſſary) may be again repeated, till you arrive to any degree of exactneſs required.

Example 1. Let it be required to approximate, by means of a vulgar fraction, the quantity 3.141926, expreſſing the periphery of a circle, whoſe diameter is unity.

Here it is plain that $\frac{a}{b}$ will be $\frac{4}{1}$, and $\frac{c}{d}=\frac{3}{1}$: therefore, by writing 4, 1, 3, 1, and 3.14, &c. in the room of a, b, c, d, and g, reſpectively, the value of x $(=\frac{a-bg}{dg-c})$ is found $=\frac{4-3.13\,\&c.}{3.14,\&c.-3}=\frac{.85,\&c.}{.14,\&c.}=6$, nearly. Whence we have $\frac{a+cx}{b+dx}=\frac{4+3\times6}{1+3\times2}=\frac{22}{7}$, for a firſt approximation, being the ſame with that of Archimedes.

Again, by taking $\frac{a}{b}=\frac{3}{1}$, and $\frac{c}{d}=\frac{22}{7}$, and ſubſtituting as before, we get $x\,(=\frac{a-bg}{dg-c})=\frac{3-3.14159}{7\times3.14159-22}=16$ nearly. Whence we have $\frac{a+cx}{b+dx}=\frac{3+352}{1+112}=\frac{355}{113}$, for a ſecond approximation; agreeing with that of Metius: which converted to a decimal, errs only in the 7th place.

Example 2. Let it be required to approximate 3.43406.

Here $\frac{a}{b}=\frac{4}{1}$, and $\frac{c}{d}=\frac{3}{1}$, whence $x=1$; and ſo $\frac{a+cx}{b+dx}=\frac{7}{2}$, for a firſt approximation.

Secondly, $\frac{c}{d}=\frac{7}{2}$, and $\frac{a}{b}=\frac{3}{1}$, therefore $x=3$, and $\frac{a+cx}{b+dx}=\frac{24}{7}$, for a ſecond approximation.

Thirdly, $\frac{c}{d}=\frac{24}{7}$, and $\frac{a}{b}=\frac{7}{2}$; and ſo $x=3$, and $\frac{a+cx}{b+dx}=\frac{79}{23}$, a third approximation.

Fourthly, $\frac{c}{d}=\frac{79}{23}$, and $\frac{a}{b}=\frac{24}{7}$; whence $x=2$, and $\frac{a+cx}{b+dx}=\frac{182}{53}$; a fourth approximation. Proceeding in this manner, we may continually approach the value of the propoſed decimal fraction.

FRACTURE, in ſurgery, a rupture of a bone; or a ſolution of continuity in a bone, when it is cruſhed or broken by ſome external cauſe.

The word is Latin, *fractura*, and derived from *frango*, to break.

Surgeons generally divide fractures into three ſpecies, or thoſe of the ſimple, compound, and complicated kinds. A ſimple fracture is produced when only one bone is broken in one part, without any conſiderable injury done to the ſuperincumbent or adjacent parts. But where ſuch fracture happens in thoſe parts of the body where two large bones are contiguous to each other, in the cubit, for inſtance, when the radius is broken, whilſt the ulna remains entire, this ſpecies of fracture is by ſurgeons called incomplete, becauſe the ſituation of the parts is not much changed, and the length of the member remains the ſame. But when the ulna and radius, or the tibia and fibula in the leg, are both broken, this is called a complete or compound fracture; though we may alſo properly enough call it a compound fracture, where only one bone is broken in ſeveral parts. But where, beſides the fracture of one or more bones, there is a train of ſymptoms which requires a particular method of cure, ſuch as a wound or ulcer; then it is called a complicated fracture, becauſe in the cure of ſuch a diſorder, particular regard is to be had to the concomitant ſymptoms; but it is ſufficiently obvious, that a fracture cannot properly be ſaid to be complicated, unleſs the abovementioned ſymptoms are preſent in a very conſiderable degree; for a fracture cannot be produced without ſome degree of contuſion, and a ſlight inflammation is almoſt always ſubſequent to fractures. Hence a fracture is only ſaid to be complicated, when the concomitant ſymptoms are of ſuch importance as to require an apparatus and method of cure different from thoſe requiſite in a ſimple or compound fracture. Thus, for inſtance, when a conſiderable wound accompanies a fracture, ſuch a dreſſing cannot be uſed as in a ſimple fracture, where it is often left unchanged for ſeveral weeks; but ſuch an apparatus is required, as may, without endangering the ſeparation of the fractured and reduced bone, be frequently removed, in order to dreſs the wound.

Fractures are differently denominated according to their different directions. A tranſverſe fracture is produced, when a bone is divided by a ſection perpendicu-

la

lar to its length. An oblique fracture, on the contrary, is ſaid to be produced, when the diviſion of the bone is not perpendicular to its longitude, but declines more or leſs from a perpendicular direction. Hence the ſurface of the fracture is the greater, and the retention of the fractured portions, when reduced, the more difficult. A longitudinal fracture is, when the bone is ſplit in a longitudinal direction; for which reaſon it is rather a fiſſure than a fracture properly ſo called, becauſe the parts of the bone are not entirely ſeparated, but as it were fiſſured in a longitudinal direction.

In curing of fractures the principal concern ſhould be the agglutination of the bone: take care therefore, 1. That it is reduced to its proper ſituation; and this is done by extenſion and repoſition. 2. After reduction, apply a proper bandage, and preſcribe reſt to your patient. 3. Prevent, or remedy, the inconveniencies that may enſue; and the ſurgeon will be qualified for this, if he knows, 1. How the bones are ſituated, whether there are one or more in the limb; whether they are large or ſmall, robuſt or ſpongy, even or uneven; and whether one or more be fractured. 2. What muſcles are near, with their poſition and office. 3. Whether any of the larger nerves, veins, or arteries, are near: for a thorough knowledge of theſe things conduces very much to a ſucceſsful cure.

When the fractured bones continue in their natural poſition, a proper bandage will promote the agglutination of the fragments, without repoſition or extenſion; though, as often as they recede from each other, ſome degree of extenſion is abſolutely neceſſary, which muſt always be proportioned to the diſtortion of the fragments; for the wider the ſeparation and the ſhorter the limb, from a contraction of the muſcles, the greater extenſion is required. But this operation muſt be performed tenderly, leſt too great violence ſhould injure the patient.

In extending a fractured limb, care is to be taken, 1. That the patient is kept ſteady, to prevent his giving way to the extenſion. The poſture muſt be accommodated to the circumſtances; for ſometimes ſitting in a chair, or on the floor, ſometimes lying on a bed, or table, is more commodious. 2. The broken limb, both above and below the fracture, muſt be held by an aſſiſtant. 3. The aſſiſtant who holds the lower part muſt extend it with ſtrength ſufficient to replace the fragments. But, if the hands alone are not ſufficient, uſe a rope or napkin; and if one man is not enough, employ two or three. Obſerve always to proceed with tenderneſs, that you may not rack the patient with unneceſſary tortures.

There remains one very important obſervation relative to the extenſion of fractured bones, which is, that if the ſurgeon is called in after tumours, or violent inflammations come on, he ought to defer the extenſion, till they are removed; for, under theſe circumſtances, the parts affected cannot be handled, compreſſed, or extended, without much acute pains, convulſions, and the danger of a ſphacelus: but if the tumor or inflammation are ſlight, we may eaſily proceed to extenſion directly, in order to prevent their increaſe.

FRÆNUM, in anatomy, a term applied to ſome membranous ligaments of the body. As,

FRÆNUM LINGUÆ, the ligament under the tongue; which ſometimes ties it down too cloſe to the bottom of the mouth, and then requires to be inciſed or divided, in order to give this organ its proper and free motion. This diſorder generally ariſes in infants ſoon after their birth, ſo that they cannot move and exert their tongues in the action of ſucking: though it is ſometimes alſo obſerved in adults.

Each of the lips has alſo its peculiar frænum: the upper one under the noſe; the under one near the roots of the dentes inciſores: theſe are of the utmoſt ſervice to us in ſpeaking, and eating and drinking.

FRÆNUM PENIS, a ligament of the penis, that ties the prepuce to the lower part of the glans of the PENIS. See PENIS.

There is alſo a ſmall frænum of the clitoris, by which it is connected to the oſſa pubis. See the article CLITORIS.

FRAGARIA, the ſtrawberry, in botany, a genus of plants, the corolla of which conſiſts of five roundiſh patent petals, inſerted in the cup: there is no pericarpium; the common receptacle of the ſeed is of a roundiſh, oval figure, plane at the baſe, pulpoſe, large, ſoft, and deciduous; the ſeeds are numerous, ſmall, acuminated, ſcattered over the ſuperfices of the receptacle, and not deciduous.

FRAIL, a baſket made of ruſhes, or the like, in which are packed up figs, raiſins, &c. It ſignifies alſo a certain quantity of raiſins, about ſeventy-five pounds.

FRAISE, in fortification, a kind of defence, conſiſting of pointed ſtakes, ſix or ſeven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, or the like, to prevent any approach or ſcalade.

Fraiſes differ from paliſades chiefly in this, that the latter ſtand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly ſo, being uſually made a little ſloping, or with points hanging down. Fraiſes are chiefly uſed in retrenchments and other works thrown up of earth; ſometimes they are found under the parapet of a rampart, ſerving inſtead of the cordon of ſtone uſed in ſtone-works.

To FRAISE *a Battalion*, is to line the muſqueteers round with pikes, that, in caſe they ſhould be charged with a body of horſe, the pikes being preſented, may cover the muſqueteers from the ſhock of the horſe, and ſerve as a barricade.

FRAME, in joinery, a kind of caſe, wherein a thing is ſet or incloſed, or even ſupported, as a window-frame, a picture-frame, &c.

FRAME is alſo a machine uſed in divers arts; as,

FRAME, among printers, is the ſtand which ſupports the caſes. See the article CASE.

FRAME, among founders, a kind of ledge incloſing a board, which, being filled with wetted ſand, ſerves as a mould to caſt their works in. See FOUNDERY.

FRAME is more particularly uſed for a ſort of loom, whereon artificers ſtretch their linens, ſilks, ſtuffs, &c. to be embroidered, quilted, or the like.

FRAME, among painters, a kind of ſquare, conſiſting of four long ſlips of wood joined together, whoſe intermediate ſpace is divided by threads into ſeveral little ſquares like a net? and hence ſometimes called reticula. It ſerves to reduce figures from great to ſmall; or, on the contrary, to augment their ſize from ſmall to great.

FRAMING *of an Houſe*, among carpenters, denotes all the timber-work therein; namely, the carcaſe, flooring, partitioning, roofing, cieling, beams, aſhlering, &c. all together. See FLOORING, &c.

FRANCE, a large kingdom of Europe, ſituated between the fifth degree weſt, and ſeventh degree eaſt longitude, and between the forty-third and fifty-firſt degree north latitude, being bounded by the Engliſh Channel and the Auſtrian Netherlands, on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the eaſt; by the Mediterranean ſea, and the Pyrenean mountains, which ſeparate it from Spain, on the ſouth; and by the Bay of Biſcay, on the weſt. This kingdom was formerly divided into twelve provinces, but at preſent it is divided into twenty-five general governments, over every one of which is an officer, called an intendant, appointed by the king, who has a power of controuling the governor, and all other officers of juſtice; and preſides over the receiver-general of his generality.

FRANCHISE, in a general ſenſe, a privilege or exemption from ordinary juriſdiction; as that for a corporation to hold pleas among themſelves to ſuch a value, or the like.

FRANCHISE is ſometimes uſed for an immunity from a tribute, in which ſenſe it is either perſonal or real; that is, belonging to a perſon immediately, or elſe by means of this or that place of which he is chief, or a member.

FRANCHISE is alſo uſed for an aſylum or ſanctuary, where people are ſecure of their perſons. See ASYLUM.

FRANCISCAN MONKS, FRIARS-MINOR, or GREY-FRIARS, religious of the order of St. Francis; founded by him in the year 1209. See the article FRIAR.

FRANK LANGUAGE, or LINGUA FRANCA, a kind

of jargon ſpoken in the Mediterranean, and particularly throughout the coaſts and parts of the Levant, compoſed of Italian, Spaniſh, French, vulgar Greek, and other languages.

FRANK-LAW, a word applied to the free and common law of the land, or the benefit a perſon has by it.

FRANK-PLEDGE, in our law, ſignifies a pledge or ſurety for the behaviour of freemen.

FRANKINCENSE, *Thus*, in the materia medica. See the article THUS.

FRANKS, FRANKIS, or FRANQUIS, an appellation given by the Turks, and other nations of Aſia, to all the inhabitants of the weſtern parts of Europe, to which they give the name of Frankiſtan.

FRAPPING, among ſailors, the act of croſſing and drawing together the ſeveral parts of a tackle, or other complication of ropes drawn tight to ſecure any body. The frapping always increaſes the tightneſs, or of courſe adds to the ſecurity acquired by the purchaſe.

FRAPPING *a Ship*, paſſing four, five, or ſix turns of a cable round the body or hull of a ſhip in the middle, to ſecure her in a great ſtorm, when it is apprehended ſhe has not ſufficient ſtrength to reſiſt the violent efforts of the waves: this expedient, however, is rarely put in practice, unleſs in very old ſhips, which the owners are willing to venture till the laſt.

FRATERNITY, in the Roman catholic countries, ſignifies a ſociety for the improvement of devotion.

FRATERNITY, in a civil ſenſe, a company or gild of certain artificers or traders. See the articles COMPANY and GILD.

FRATRICELLI, LITTLE BROTHERS, in church-hiſtory, a ſect of heretics who appeared in Italy about the year 1298, and afterwards ſpread all over Europe. They wore the habit of the Franciſcan order, and pretended that eccleſiaſtics ought to have no poſſeſſions of their own.

FRATRIAGE, *Fratriagium*, the partition among brothers or coheirs, coming to the ſame inheritance or ſucceſſion.

FRATRICIDE, the crime of murdering one's brobrother. See PARRICIDE.

FRAUD, in law, ſignifies deceit in grants or conveyances of lands, &c. or in bargains and ſales of goods, &c. to the damage of another perſon.

FRAXINUS, the aſh, in botany. See the article ASH.

FREAM, a name given by farmers to ploughed lands worn out of heart, and laid fallow till it recovers. See FALLOWING.

FRECKLES, *Lentigines*, in medicine, ſmall, yelloviſh, or duſky ſpots appearing on the ſkin, chiefly about the face, neck, and hands. It is moſtly a natural affection cauſed by the heat of the ſun, whereby ſome parts of the ſkin appear of a darker colour than uſual, called tan, ſunburn, and morphew, which differ only in degree, and uſually diſappear in winter.

Freckles are generally more numerous about the forehead and noſe than in any other parts of the face, and in ſize commonly equal the ſcale of a herring. Tan uſually ſpreads all over the face, the ſpots thereof being much larger than freckles: perſons of a delicate complexion, or ſuch whoſe hair is red, are moſt ſubject to freckles, eſpecially in thoſe parts which are expoſed to the air; and they are very hard to remove.

Mr. Homberg's medicine, which is compoſed of bullock's gall mixed with alum, and after the alum is precipitated, expoſed three or four months in the ſun in a cloſe phial, is the beſt remedy.

FREE, in a general ſenſe, is uſed in oppoſition to whatever is conſtrained or neceſſitated. When applied to things endowed with underſtanding, it more peculiarly relates to the liberty of the will.

FREE-BENCH, ſignifies that eſtate in copyhold which the wife, being eſpouſed a virgin, has after the deceaſe of her huſband for her dower, according to the cuſtom of the manor.

FREE-STATE, a republic governed by magiſtrates elected by the free ſuffrages of the inhabitants.

FREE-STONE, a whitiſh ſtone dug up in many parts of England, that works like alabaſter, but is more hard and durable; being of excellent uſe in building, &c. It is a kind of the grit ſtone, and is called free, from its being of ſuch a conſtitution as to cut freely in any direction: ſuch is the Portland-ſtone, and the free-ſtone of Kent.

FREE-THINKER. See the article DEIST.

FREE-WARREN, the power of granting or denying licenſe to any one to hunt in ſuch and ſuch ground.

FREE *the Boat*, or bale the boat, among ſailors, throw out the water.

FREEDOM, in general, the ſtate or quality of being free.

FREEDOM *of a Corporation*, the right of enjoying all the privileges and immunities belonging to it.

FREEDOM *of the Will*, that power or faculty of the mind whereby it is capable of acting, chuſing or rejecting whatever it judges proper. Of this every man muſt be ſenſible, who finds in himſelf a power to begin or forbear, continue or end ſeveral actions, barely by a thought or preference of the mind. The actual exerciſe of this power, is that which we call volition or willing; and the agent capable of acting in this manner, is denominated free, and the actions he performs, voluntary. Whereas, on the other hand, wherever any performance or forbearance are not equally in a man's power; wherever doing or not doing will not equally follow upon the preference of his mind, there he is not free, though perhaps the action may be voluntary. To illuſtrate this, ſuppoſe a man to be carried whilſt faſt aſleep into a room where is a perſon he longs to ſee, and be there locked faſt in, beyond his power to get out, he awakes, and is glad to ſee himſelf in ſo deſireable company, which he ſtays willingly in; that is, prefers his ſtaying to going away. In this caſe, his ſtay is voluntary; and yet, being locked faſt in, he is not at liberty to ſtay, he has not freedom to be gone. So that liberty does not conſiſt in the preference of the mind, but in the power of conforming to that preference.

FREEDOM *of Contrariety*, among moraliſts, that of chuſing either of two oppoſites, as virtue or vice, good or evil; concerning which the received doctrine is, that mankind have a freedom of contradiction, but not of contrariety; that is, they may abſtain from the purſuit of virtue and good, but are incapable of hating them, or of preferring their oppoſites. See the article CONTRADICTION.

FREEZE, or FRIEZE, in architecture. See the article FRIEZE.

FREEZE, or FRIEZE, in commerce, a coarſe kind of woollen ſtuff, or cloth, for winter wear; ſo called, as being freezed or napped on one ſide.

FREEZING, in philoſophy, the ſame with congelation. See CONGELATION and FROST.

Philoſophers are by no means agreed as to the cauſe of this phœnomenon. The Carteſians account for it by the receſs or going out of the ætherial matter from the pores of the water. The Corpuſcularians, on the other hand, attribute it to the ingreſs of frigorific particles, as they call them: Hobbes aſſerts, that theſe particles are nothing elſe but common air, which entangling itſelf with the particles of water, prevents their motion. Others will have a kind of nitrous ſalt to be the cauſe of congelation, by inſinuating itſelf between the particles of water, and fixing them together, like nails: and indeed it ſeems probable that cold and freezing do ariſe from ſome ſubſtance of a ſaline nature, floating in the air; ſince all ſalts, and particularly nitrous ones, when mixed with ice and ſnow, greatly increaſe their cold and even bulk.

By means of freezing, wine, vinegar, and malt-liquor may be reduced to a fourth part of their quantity, without any conſiderable loſs of their eſſential parts; ſince only the aqueous parts freeze, leaving the vinous part concentrated or brought into leſs compaſs, and capable of being tranſported with leſs expence, and keeping ſeveral years.

FREEZING MIXTURE. See the article ARTIFICIAL COLD.

FREEZING, in naval affairs, a ſort of ornament painting, conſiſting of trophies, flower-work, &c. a ſhip's quarter, ſtern, or fore part immediately below the upper-edge of her ſides, called the gunnel.

FREIGHT, or FRAIGHT, in navigation and commerce, the hire of a ſhip, or a part thereof, for the conveyance and carriage of goods from one part or place to another; or the ſum agreed on between the owner and the merchant, for the hire and uſe of a veſſel.

FREIGHT, is alſo uſed for the burden or lading of a ſhip, or the cargo of goods, &c. which ſhe has on board.

FREIGHT alſo ſignifies a duty of fifty ſols per tun, paid to the crown of France by the maſters of foreign veſſels going in or out of the ſeveral ports of that kingdom.

FRENUM, or FRÆNUM, in anatomy. See FRÆNUM.

FRENZY, or PHRENZY, in medicine. See the article PHRENZY.

FRESCO, a method of painting in relievo on walls, ſo as to endure the weather.

It is performed with water-colours on freſh plaiſter; or on a wall laid with mortar not yet dry. This ſort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

The compoſt ſhould be made of rubbiſh ſtones mixed with well-burnt flint, or lime, and water; but the ſaltneſs of the lime muſt be waſhed out, by pouring water frequently on it; but this ſhould not be done in moiſt weather.

To prevent the plaiſter from pealing, ſtrike into the joints of the wall ſtumps of horſe-nails ſix inches diſtant from each other. Firſt, plaiſter the walls pretty thick, then let it dry for ſome time, the deſign and colours being firſt ready prepared. This painting is chiefly performed on walls and vaults newly plaiſtered with lime and ſand; and the plaiſter is only to be put on in proportion as the painting proceeds.

Plaiſter the wall a ſecond time, about the thickneſs of half a crown, only ſo much as you intend to work upon; and, while it is wet, work the colours therein, which will incorporate with the plaiſter ſo as never to waſh out.

The painting muſt be worked with a free-hand, and your colours made high enough at firſt, as there can be no alteration made after the firſt painting.

In this work ſcarce any thing elſe is uſed but earths, which ſtill retain their colour, defending it from the burning and ſalt of the lime. The colours are white, made of lime ſlacked ſome time, and white marble duſt, red and yellow ochre, violet red, verditer, lapis lazuli, ſmalt, black Spaniſh brown, Spaniſh white, &c. all which are ground and worked up with water.

The bruſhes and pencils for this work muſt be long and ſoft, or elſe they will rake and raze the painting; the colours muſt be full and flowing from the bruſh, and the deſign or cartoon muſt be perfect in the paper-copy.

The ancients painted on ſtucco; and we may remark in Vitruvius what infinite care they took in making the incruſtations or plaiſtering of their buildings, to render them beautiful and laſting; though the modern painters find a plaiſter made of lime and ſand preferable thereto.

FRESHEN *the Hawſe*, among ſailors, when a ſhip rides at anchor, there is always ſome canvas, mat, leather, or ſuch like matter wound about the cable in the hawſe-hole, and where it may rub againſt the ſtem: the matter uſed on this occaſion is called ſervice, and, as by the pitching and labouring of the ſhip in a ſtorm when ſhe is anchored in an open road or bay, the ſervice muſt be in a ſhort time wore through, it is neceſſary to have it frequently renewed for the preſervation of the cables, on which all depends; and this act of renewing the ſervice is called freſhening the hawſe, which is a circumſtance a ſeaman can never be too careful in obſerving. See the article HAWSE.

FRESHES, among ſailors, the violence of an ebb-tide, encreaſed by heavy rains, flowing into the ſea, which it diſcolours to a conſiderable diſtance from the ſhore on ſuch occaſions, where the line on which the two colours meet, may be diſtinctly obſerved for a great length along the coaſt.

FRET, or FRETTE, in architecture, a kind of knot or ornament, conſiſting of two liſts or ſmall fillets variouſly interlaced or interwoven, and running at parallel diſtances equal to their breadth.

Every return and interſection of theſe frets muſt be at right angles, otherwiſe they loſe all the beauty, and become perfectly Gothic. Sometimes the fret conſiſts but of a ſingle fillet, which, if well diſpoſed, may be made to fill its ſpace exceedingly well. Frets were very much uſed by the ancients, eſpecially on even flat members, or parts of a building, as the faces of the corona, and eves of corniches; under the roofs, ſoffits, &c. and on the plinths of baſes. See the articles CORONA, EVE, &c.

FRET, in heraldry, a bearing compoſed of ſix bars, croſſed, and variouſly interlaced: ſome call it the true-lover's knot.

FRET, in muſic, ſignifies a kind of ſtop on ſome inſtruments, particularly baſs-viols and lutes. Frets conſiſt of ſtrings tied round the neck of the inſtrument, at certain diſtances, within which ſuch and ſuch notes are to be found.

FRET-WORK, that adorned with frets. It is ſometimes uſed to fill up and enrich flat empty ſpaces; but is moſtly practiſed in roofs, which are fretted over with plaiſter-work. The Italians alſo uſe fretworks in the mantling of chimneys with great figures, a cheap piece of magnificence, and as durable almoſt within doors, as harder matters in the weather.

FRETTY, in heraldry, an appellation given to bearings made up of ſix, eight, or more bars laid acroſs each other, in the manner of frets.

FRIABLE, among naturaliſts, an appellation given to bodies that are eaſily crumbled to pieces: ſuch are the free-ſtone, pumice-ſtone, &c.

FRIAR, or FRIER, from the French *frere*, a brother, a term common to monks of all orders, founded on this, that there is a kind of fraternity, or brotherhood, between the ſeveral religious perſons of the ſame convent or monaſtery.

Friars are generally diſtinguiſhed into theſe four principal branches, viz. 1. Minors, grey friars, or Franciſcans. 2. Auguſtines. 3. Dominicans, or black friars. 4. White friars, or Carmelites. From theſe four the reſt of the orders deſcend. See the articles FRANCISCANS, AUGUSTINES, &c.

FRIAR, in its more peculiar and proper ſenſe, is reſtrained to ſuch monks as are not prieſts, for thoſe in orders are generally dignified with the title of father. See MONK and FATHER.

FRIAR OBSERVANT is a branch of the Franciſcan friars; thus called, becauſe they are not combined together in any cloiſter, convent, or corporation, as the conventuals are; but have bound themſelves only to obſerve the rules of their order more ſtrictly than the conventuals do, from whom they ſeparated, out of a ſingularity of zeal, living in certain places of their own chuſing.

FRIAR'S COUL, in botany, a name given to ſeveral ſpecies of arum. See the article ARUM.

FRICTION, the act of rubbing the ſurface of one body againſt that of another.

The word is Latin, *frictio*, and derived from *frico*, to rub.

Among machines, ſome have a great deal more friction than others, and ſome very little. Thus a pendulum has little or no friction, but what ariſes from the reſiſtance of the air. But a carriage has a great deal of friction: for upon plain ground a loaded cart requires the ſtrength of ſeveral horſes to draw it along; and all or moſt of this force is owing to its friction. All compounded machines have great friction, and ſo much the more as they conſiſt of more parts that rub againſt one another. And there is a great variety in ſeveral ſorts of bodies, as to the quantity of friction they have, and even in the ſame bodies under different circumſtances: upon which account it will be impoſſible to give any ſtanding rules, by which its quantity can be exactly determined. All we can do is to lay down ſuch particular rules as have been deduced from experiments made upon particular bodies; which rules will require ſome variation under different circumſtances, according to the judgment and experience of the artiſt.

1. Wood and all metals, when oiled or greaſed, have nearly the ſame friction: and the ſmoother they are, the leſs friction they have: yet metals may be ſo far poliſhed as to increaſe friction by the coheſion of their parts.

Wood ſlides eaſier upon the ground in wet weather than in dry; and eaſier than iron in dry weather: but iron ſlides eaſier than wood in wet weather. Lead makes a great deal of reſiſtance. Iron or ſteel running in braſs, makes the leaſt friction of any. In wood acting againſt wood, greaſe makes the motion twice as eaſy, or rather $\frac{2}{3}$ eaſier. Wheel-naves greaſed or tarred, go four times eaſier than when wet.

Metals oiled makes the friction leſs than when poliſhed, and twice as little as when unpoliſhed.

In general, the ſofter or rougher the bodies, the greater is their friction.

2. As to particular caſes: a cubic piece of ſoft wood of eight pounds weight, moving upon a ſmooth plane of ſoft wood, at the rate of three feet per ſecond; its friction is about $\frac{2}{3}$ the weight of it: but if it be rough, the friction is little leſs than half the weight.

Upon the ſame ſuppoſition, other ſoft wood upon ſoft wood very ſmooth, the friction is about $\frac{1}{4}$ the weight.

Soft wood upon hard or hard upon ſoft, $\frac{1}{5}$ or $\frac{1}{6}$ the weight.

Hard wood upon hard wood, $\frac{1}{7}$ or $\frac{1}{8}$ the weight.

Poliſhed ſteel moving on ſteel or pewter, $\frac{1}{4}$ the weight: moving on copper or lead, $\frac{1}{5}$ the weight: on braſs $\frac{1}{3}$ the weight. Metals of the ſame ſort have more friction than different ſorts.

The friction, *cæteris paribus*, increaſes with the weight almoſt in the ſame proportion. The friction is alſo greater with a greater velocity, but not in proportion to it, except in very few caſes. A greater ſurface alſo cauſes ſomething more friction, with the ſame weight and velocity: yet friction may ſometimes be increaſed by having too little ſurface to move on; as upon clay, &c. where the body ſinks.

3. The friction ariſing from the bending of ropes about machines, differs according to their ſtiffneſs, the temper of the weather, degree of flexibility, &c. but, *cæteris paribus*, the force or difficulty of bending a rope is as the ſquare of the diameter of the rope, and its tenſion, directly; and the diameter of the cylinder or pulley it goes about, reciprocally.

A rope of one inch diameter, whoſe tenſion, or weight drawing it, is five pounds, going over a pulley three inches diameter, requires a force of one pound to bend it.

4. The reſiſtance of a plane moving through a fluid is as the ſquare of the velocity; and putting $v =$ velocity in feet, in a ſecond, it is equal to the weight of a column of the fluid, whoſe baſe is the plane, and height $\frac{v\,v}{64}$. And in a globe it is but half ſo much.

5. The friction of a fluid running through a tube is as the velocity and diameter of the tube.

But the friction is greater in reſpect to the quantity of the fluid, in ſmall tubes than in large ones; and that reciprocally as their diameters: but the abſolute quantity of the friction in tubes is but very ſmall, except the velocity be very great, and the tube very long.

But if a pipe be divided into ſeveral leſſer ones, whoſe number is n; the reſiſtance ariſing from the friction will be increaſed as $\sqrt{n}$. For the area of the ſection of any one pipe will be $\frac{1}{n}$, and the friction being as the circumference, will be as $\frac{1}{\sqrt{n}}$; and therefore the friction in all of them, will be $\frac{n}{\sqrt{n}}$, or as $\sqrt{n}$.

6. As to the mechanic powers. The ſingle lever makes no reſiſtance by friction: but if by the motion of the lever in lifting, the fulcrum, or place of ſupport, be changed further from the weight; the power will be decreaſed thereby.

7. In any wheel of any machine, running upon an axis; the friction on the axis is as the weight upon it, the diameter of the axis, and the angular velocity. This ſort of friction is but ſmall.

8. In the pulley, if p, q, be two weights, and q the greater; and $W = \frac{4pq}{p+q}$; then W is the weight upon the axis of the ſingle pulley: and it is not increaſed by the acceleration of the weight q, but remains always the ſame.

The friction of the pullies is very conſiderable, when the ſheaves rub againſt the blocks; and by the wearing of the holes and axels.

The friction on the axis of the pulley is as the weight W, its angular velocity, the diameter of the axis directly, and the diameter of the pulley inverſly. A power of one hundred pounds, with the addition of fifty pounds, will but draw up five hundred pounds with a tackle of five; and fifteen pounds over a ſingle pulley will draw up only fourteen pounds.

9. In the ſcrew, there is a great deal of friction: thoſe with ſharp threads have more friction than thoſe with ſquare threads: and endleſs ſcrews have more than either. Screws with a ſquare thread raiſe a weight with more eaſe than thoſe with a ſharp thread.

In the common ſcrew the friction is ſo great, that it will ſuſtain the weight in any poſition given, when the power is taken off; and therefore the friction is at leaſt equal to the power. From whence it will follow, that in the ſcrew

The power muſt be to the weight or reſiſtance, at leaſt as twice the perpendicular height of a thread, to the circumference deſcribed by one revolution of the power; if it be able to raiſe the weight, or only ſuſtain it. This friction of the ſcrew is of great uſe, as it ſerves to keep the weight in any given poſition.

10. In the wedge, the friction is at leaſt equal to the power, as it retains any poſition it is driven into; therefore in the wedge, the power muſt be to the weight at leaſt as twice the baſe to the height to overcome any reſiſtance.

11. To find the friction of any engine, begin at the power, and conſider the velocity and the weight at the firſt rubbing part; and eſtimate its quantity of friction by ſome of the foregoing articles; then proceed to the next rubbing part and do the ſame for it, and ſo on through the whole.

And note, that ſomething more is to be allowed for increaſe of friction, by every new addition to the power.

FRICTION, in medicine, the rubbing a diſeaſed part, either with or without unguents, oils, &c. Dr. Cheyne greatly recommends friction with a flesh-brush to perſons of weak nerves and ſedentary lives; by which means a full and free perſpiration would be promoted, and obſtructions removed, to the great relief of many valetudinarians.

FRIEZE, FREEZE, or FRIZE, in architecture, a large flat face, or member, ſeparating the architrave from the corniche, being that part of the entablature between the architrave and corniche.

This member was by the ancients called zoophorus, becauſe it was commonly enriched with the figures of animals. The frieze is ſuppoſed to be deſigned to repreſent the heads of the tranſverſe beams, which ſuſtain the roof or covering.

In the Tuſcan order it is quite plain, but is enriched with triglyphs in the Doric; it is ſometimes made arched or ſwelling in the Ionic: in the Corinthian and Compoſite it is frequently joined to the architrave by a little ſweep, and ſometimes to the corniche; and in theſe richer orders, it is commonly adorned with ſculpture, figures, compartments, hiſtories, foliages, feſtoons, &c.

As to the height of the frieze, it is in general much the ſame as that of the architrave. The height of the Tuſcan frieze, according to Vitruvius, who makes it flat and plain, is 30 minutes; but Palladio, who makes it convex and ſwelling, gives it only 26; Scamozzi makes it plain, but raiſes the height to 42 minutes. Vitruvius and Vignola, who make the Doric frieze flat, only covered with triglyphs, give it the height of 30 or 40 minutes: but Palladio and Scamozzi make it 45. The Ionic frieze, according to Vitruvius, who makes it flat, only carved with acanthus-leaves, &c. is 30 minutes in height; Vignola makes it 45, and ſa like

like Vitruvius: Palladio, who makes it convex and ſwelling, calls the height 27; and Scamozzi 28. The height of the Corinthian frieze, according to Vitruvius, who enriches it with acanthus-leaves, human figures, &c. is 37 minutes; but Vignola makes it 45; Palladio, 28; and Scamozzi 31 ½. Laſtly, the Compoſite frieze, which, in Vitruvius, is ſet with cartouſes, and carved between them, is, according to that writer, 52 ½ minutes high; but Vignola, who makes it like Vitruvius, gives it but 45 minutes; Palladio, who makes it ſwelling, has but 30; Scamozzi, 32.

From the variety of their ornaments, friezes obtain various denominations.

Convex or *Pulvinated* FRIEZES, ſuch whoſe profile is a curve, the beſt proportion of which is when drawn on the baſe of an equilateral triangle.

In ſome the ſwelling is only at top, as in a conſole; in others at bottom, as in a balluſter.

Flouriſhed FRIEZES, ſuch as are enriched with rinds of imaginary foliages, as the Corinthian frieze of the frontiſpiece of Nero: or with natural leaves, either in cluſters or garlands; or continued, as in the Ionic of the gallery of Apollo in the Louvre.

Hiſtorical FRIEZES, ſuch as are adorned with baſs relievos, repreſenting hiſtory, ſacrifices, &c. as the arch of Titus at Rome.

Marine FRIEZES, ſuch as repreſent ſea-horſes, tritons, and other attributes of the ſea, as ſhells, baths, grottos, &c.

Ruſtic FRIEZES, ſuch whoſe courſes are ruſticated or emboſſed, as in the Tuſcan frieze of Palladio.

Symbolical FRIEZES, thoſe adorned with the attributes of religion, as the Corinthian of the temple behind the Capitol at Rome; whereon are repreſented the inſtruments and apparatus of ſacrifice.

FRIGATE, in the marine, a light nimble ſhip, built for quick ſailing: frigates carry from twenty to thirty-eight cannon, and are eſteemed excellent cruiſers.

Formerly the name of frigate was only known in the Mediterranean; and given to a kind of long veſſel, which they made uſe of in thoſe ſeas; and went with ſails and oars. The Engliſh were the firſt who appeared on the ocean with thoſe ſhips; and fitted them for action as well as ſailing.

FRIGID, is applied to a jejune ſtile, that is unanimated by any ornaments, and conſequently without any force or vigour.

FRIGID ZONE, in geography. See the article ZONE.

FRIGORIFIC, in phyſiology, ſmall particles of matter, which, according to Gaſſendus and others, being actually and eſſentially cold, and penetrating other bodies, produce in them that quality which we call cold. See COLD.

FRIST, in the mercantile ſtyle, ſignifies ſelling goods upon credit, or truſt.

FRIT, in the glaſs manufacture, the matter or ingredients of which glaſs is to be made, when they have been calcined or baked in a furnace; or it is the calcined matter to be run into glaſs. See GLASS.

There are three kinds of frit; the firſt, that made for cryſtal; the ſecond, or ordinary frit, is that made for the common white or cryſtalline metal; and the third, that made for green glaſs.

The frit for cryſtal is made as follows: take two hundred pounds of tarſo, powdered fine, and ſifted; of the ſalt of polverine, one hundred and thirty pounds; mix them well together, and put them in the calcar, a ſort of oven, or reverberatory furnace, which ſhould firſt be well heated: here let them remain, baking, frying, and calcining, for five hours, during which the workman keeps mixing them with a rake, to make them incorporate.

The ſecond or ordinary frit is made of bare aſhes of polverine, without extracting the ſalt from them.

The third, for green graſs, is made of common aſhes, without any preparation.

It may be obſerved, that glaſs might be made by immediately melting the materials, without this calcining and making them into frit; but the operation would be much more tedious.

FRIZING *of Cloth*, a term in the woollen manufactury, applied to the forming of the nap of a cloth, or ſtuff, into a number of little hard burrs or prominences, covering almoſt the whole ground thereof.

Some cloths are only frized on the back-ſide, as black cloths; others on the right-ſide, as coloured and mixed cloths, rateens, baize, freezes, &c.

Frizing may be performed two ways; one with the hand, that is, by means of two workmen, who conduct a kind of plank that ſerves for a frizing inſtrument.

The other way is by a mill, worked either by water, or a horſe, or ſometimes by men. This latter is eſteemed the better way of frizing, by reaſon the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The ſtructure of this uſeful machine is as follows.

The three principal parts are the frizer or criſper, the frizing-table, and the drawer, or beam. The two firſt are two equal planks or boards, each about ten feet long, and fifteen inches broad, differing only in this, that the frizing-table is lined or covered with a kind of coarſe woollen ſtuff, of a rough ſturdy nap; and the frizer is incruſtated with a kind of cement compoſed of glue, gum arabic, and a yellow ſand, with a little aqua vitæ or urine. The beam, or drawer, thus called becauſe it draws the ſtuff from between the frizer and the frizing-table, is a wooden roller, beſet all over with little, fine, ſhort points, or ends of wire, like thoſe of cards uſed in carding of wool.

The diſpoſition and uſe of the machine is thus: the table ſtands immoveable, and bears or ſuſtains the cloth to be frized, which is laid with that ſide uppermoſt on which the nap is to be raiſed: over the table is placed the frizer, at ſuch a diſtance from it as to give room for the ſtuff to be paſſed between them, ſo that the frizer, having a very ſlow ſemicircular motion, meeting the long hairs or naps of the cloth, twiſts and rolls them into little knobs or burrs, while, at the ſame time, the drawer, which is continually turning, draws away the ſtuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is a going, is to ſtretch the ſtuff on the table, as faſt as the drawer takes it off; and from time to time to take off the ſtuff from the points of the drawer.

The deſign of having the frizing-table lined with ſtuff of a ſhort, ſtiff, ſtubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which muſt otherwiſe be the caſe, as it is not held by any thing at the other end. It were unneceſſary to ſay any thing particular of the manner of frizing ſtuffs with the hand, it being the aim of the workmen to imitate, as near as they can with their wooden inſtrument, the ſlow, equable, and circular motion of the machine: in needs only be added, that their frizer is but about two feet long and one broad; and that, to form the nap more eaſily, they moiſten the ſurface of the ſtuff lightly, with water mingled with whites of eggs or honey.

FROG, *Rana*, in zoology, a genus of amphibious animals, the body of which is broad and ſhort, without a tail, and furniſhed with four legs.

FROG, among farriers, the ſame with ſruſh. See FRUSH.

FRONDES, among botaniſts, denote leaves conſiſting of ſeveral other leaves, and forming the whole of the plant; as is the caſe of the fern-kind, in which, the fructification being on the back of the leaves, the ſingle leaf makes the whole plant, and is called frondis, not folium.

FRONT *of a Battalion*, among military men, is the firſt rank, or file-leaders. It is likewiſe called the face or head of a battalion.

FRONT *of a Place*, or the TENAILLE, in fortification, all that is contained between the flanked angles of the two neighbouring baſtions, viz. the two faces, two flanks, and the curtain.

FRONT, in architecture, the principal face or ſide of a building, or that which is preſented to the chief aſpect or view.

FRONT, in perſpective, a projection or repreſentation of the face or forepart of an object, or of that part directly oppoſite to the eye, which is more uſually called the orthography. See ORTHOGRAPHY.

FRONTAL,

FRONTAL, in architecture, a little fronton, or pediment, ſometimes placed over a little door, or window.

FRONTAL, or FRONTLET, or BROW-BAND, is alſo uſed in ſpeaking of the Jewiſh ceremonies.

This frontal conſiſts of four ſeveral pieces of vellum, on each whereof is written ſome text of Scripture: they are all laid on a piece of calf's leather, with thongs to tie it by.

The Jews apply the leather with the vellum on their foreheads in the ſynagogue, and tie it round the head with the thongs.

FRONTALE, in medicine, a name for any external medicine, or topic, applied to the forehead: more particularly it means a refrigrating and hypnotic remedy, prepared of cold cephalics, bruiſed and tied up in a linen bag, four or five fingers-breadth.

FRONTATED, a term uſed by botaniſts relating to the leaf of a flower, which grows broader and broader, perhaps terminating in a right line: and is uſed in oppoſition to cuſpidated, that is, when the leaves of the flower end in a point.

FRONTIER, the border, confine, or extremity of a kingdom or province, which the enemies find in front, when they would enter the ſame: thus we ſay, a frontier town, a frontier province, &c. Frontiers were anciently called marches.

FRONTIS Os, in anatomy, called alſo os coronale, the bone of the forehead.

This is a bone of the cranium, of an irregular form, double in infants, but in adults uſually ſingle: ſometimes however, it is divided in theſe into two parts down to the noſe. It is ſituated in the anterior part of the ſkull, and forms that part of the face which is called the forehead, from whence it has its name. Its figure is ſymmetrical, reſembling a large ſhell, almoſt round. See the article SKULL.

The os frontis is articulated, by ſuture, to ſeven other bones; the oſſa parietalia, os othmoides, os ſphenoides, oſſa lachrymalia, oſſa naſi, maxillaria, and the oſſa malarum. See the articles SUTURE, OSSA PARIETALIA, &c.

The os frontis contains the anterior lobes of the brain, and a portion of the longitudinal ſinus; and forms the forehead, the upper parts of the orbits, and a portion of the temples. See BRAIN.

In the internal ſurface of the os frontis there is a fovea, or furrow, and an eminence, to which the longitudinal ſinus of the dura mater adheres: on its external ſurface are ſituated the frontal and temporal muſcles, and the cartilaginous annule of the muſculus trochlearis of the eye. See MUSCULUS TROHCLEARIS, &c.

FRONTISPIECE, in architecture, the portrait or principal face of a building. See BUILDING.

FRONTISPIECE is alſo uſed to ſignify an ornament fronting the title page of a book, which, in ſome meaſure, ſhould expreſs the ſubject treated of.

FRONTON, in architecture, the ſame with pediment. See the article PEDIMENT.

FROST, in phyſiology, ſuch an exceſſively cold ſtate of the air, as converts watery fluids into ice. See the articles FREEZING and ICE.

FROTH, a white light ſubſtance, formed on the ſurface of fluids, by vehement agitation; conſiſting of little ſphericles, or globules.

FROTH-SPITTLE, or CUCKOO-SPITTLE, a name given to a white froth, or ſpume, very common in the ſpring, and firſt months of the ſummer, on the leaves of certain plants, particularly on thoſe of the common white field lychnis, or catch-fly, thence called by ſome ſpatling poppy.

All writers on vegetables have taken notice of this froth, though few have underſtood the cauſe or origin of it till of late; being formed by a little leaping animal, called by ſome the flea-graſhopper; by applying its anus cloſe the leaf, and diſcharging thereon a ſmall drop of a white viſcous fluid, which, containing ſome air in it, is ſoon elevated into a ſmall bubble: before this is well-formed, it depoſits ſuch another, and ſo on, till it is every way overwhelmed with a quantity of theſe bubbles, which form the white froth which we ſee.

FRUCTIFEROUS, ſignifies properly any thing that produces fruit; but, in a more large and figurative ſenſe, it is uſed by ſome, particularly lord Bacon, for ſuch experiments in natural philoſophy, as prove advantageous to the experimenter in point of gain or profit.

FRUCTIFICATION, among botaniſts, in a more lax ſenſe, includes the flower and fruit, with their ſeveral coverings. See the articles FLOWER and FRUIT.

Strictly ſpeaking, however, the term fructification ſignifies only the male and female organs of generation, called the ſtamina and piſtil.

FRUGIVOROUS BIRDS are ſuch as feed on fruits, either wholly or in part.

FRUIT, in general, includes whatever the earth produces for the nouriſhment and ſupport of a man, and other animals, as herbs, grain, hay, corn, &c. See the article HERBS, GRAIN, &c.

FRUIT more properly ſignifies the production of a tree, or plant, for the propagation or multiplication of its kind, in which ſenſe the word takes in all kinds of ſeeds, with their furniture. But botaniſts, uſually underſtand by it that part of a plant wherein the ſeeds are contained. See PLANT and SEED.

FRUIT alſo implies an aſſemblage of ſeeds in a head; as in a ranunculus, &c. and all kinds of ſeeds, or grains, whether incloſed in a cover, capſule, or pod; and whether bony, fleſhy, ſkinny, membranous, or the like.

The fruit in all plants, is the product, or reſult, of the flower; or that for the production and nutrition of which the flower was intended.

The ſtructure and parts of different fruit differ in ſome things, but in all the ſpecies, the eſſential parts of the fruit appear to be only continuations or expanſions of thoſe which are ſeen in the other parts of the tree; and the ſame fibres are continued to them from the root. An apple, cut in two tranſverſely, will be found principally compoſed of four parts. 1. A ſkin, or rind, which is only a continuation and expanſion of the outer bark of the tree. 2. A parenchyma, or pulp, which is an expanſion and intumeſcence of the blea, or inner bark of the tree. 3. The fibres, or ramifications of the woody part of the tree. 4. The core, which is the produce of the pith of the wood, indurated, or ſtrengthened by twigs of the woody fibres intermixed with it. This ſerves to furniſh a proper lodging for the ſeeds, and filtrates the juices of the parenchyma, or pulp, and conveys them to the ſeeds.

FRUITERY, a place for the keeping of fruit, a fruit-houſe, or fruit-loft.

A fruitery ſhould be inacceſſable to any thing of moiſture, and ſhould be as much as poſſible ſo even to froſt.

FRUMENTACEOUS, a term applied, by botaniſts, to all ſuch plant as have a conformity with wheat, in reſpect of their fruits, leaves, ears, or the like.

FRUSH, or FROG, among farriers, a ſort of tender horn which ariſes in the middle of a horſe's ſole; and, at ſome diſtance from the toe, divides into two branches, running towards the heel, in the form of a fork.

The fruſh is a part of a horſe's foot, the top of which only ſhould be pared, and that every time the foot is pared, otherwiſe it is apt to corrupt.

FRUSTUM, in mathematics, a part of ſome ſolid body ſeparated from the reſt.

FRUSTUM, of a pyramid, or cone, is a piece or part thereof cut off, generally by a line parallel to the baſe. The ſolidity of the fruſtum of a ſquare pyramid may be found by the following theorem.

To the rectangle of the ſides of the two baſes add the ſum of their ſquares; that ſum being multiplied into one third of the fruſtum's height, will give its ſolidity.

The ſolidity of the fruſtum of a cone may be found by the following theorem.

To three times the rectangle of the two diameters add the ſquare of their difference; that ſum multiplied by the height will give the ſolidity.

FRUTICOSE STALKS, among botaniſts, thoſe with a hard woody ſubſtance. See STALK.

FUCUS, is botany, a genus of ſubmarine plants belonging to the cryptogamia claſs of Linnæus.

The fucus conſiſts of a tough matter, formed into a kind of leaves, which are flat and variouſly divaricated; and

and which have ſome appearance of fructification, in punctated tubercles, covering oblong veſicles, ſuppoſed by Linnæus to be male flowers; and ſmooth, roundiſh veſicles, hollow and interwoven with filaments, which appear to him to be female flowers.

There are a great many ſpecies of fucus with broader or narrower leaves, and other peculiarities; one of which, the broad-leaved, ſerrated fucus, grows to the height of ſix, eight, or more inches.

FUGITIVE, a perſon obliged to fly his country, or remove from a place where he had ſome abode, or eſtabliſhment, on account of his crimes, debts, or other occaſions.

FUGUE, in muſic, is when different parts of a muſical compoſition follow each other, each repeating what the firſt had performed.

There are three kinds of fugues; the ſimple, double, and counter.

Single, or *Simple* FUGUE, is ſome point conſiſting of four, five, or more notes begun by one ſimple part, and ſeconded by a ſecond, third, fourth, fifth, &c. if the compoſition conſiſt of ſo many; repeating the ſame or ſuch like notes, that is, in the ſame proportion, ſo that the ſeveral parts follow, or come in one after another, in the ſame manner; the leading part ſtill flying before thoſe that follow.

FUGUE DOUBLE, or FUGA DOPPIA, is when two or more different points move together in a fugue, and are alternately mixed and interchanged by the ſeveral parts.

FULCRUM, in mechanics, the prop or ſupport by which a lever is ſuſtained. See the article LEVER.

FULICA, the coot, in ornithology, a genus of birds, of the order of the gallinæ, with a naked or bald forehead, and divided or cloven feet: add to this, that all the toes are longer than in whole footed birds, and have ſemicircular membranes affixed to their joints.

FULIGINOUS, whatever proceeds from a thick, ſooty ſmoke, ſuch as litharge and lamp-black.

FULL-MOON, *plenilunium*, that phaſis of the moon when, in her oppoſition to the ſun, the whole of her diſk is illuminated; in which time eclipſes of the moon can only happen. See the articles MOON and ECLIPSE.

FULLER, a workman employed in the woollen manufactories, to mill, or ſcour, cloths, ſerges, and other ſtuffs, in order to render them more thick, compact, and durable. See CLOTH.

FULLER'S EARTH, *cimolia purpuraſcens*, a kind of marle of a cloſe texture, and of a tolerably ſmooth and gloſſy ſurface, when it has been rubbed. It is extremely ſoft and unctuous to the touch, of a greyiſh brown-colour, with ſome admixture of the olive or greeniſh.

The fineſt fuller's earth in the world is dug in England, and all the nations round us would gladly purchaſe it at a great price, were the exportation of it allowed; but one of the great advantages of our woollen manufactory is the keeping it at home. Large quantities of it are dug near Wooburn in Bedfordſhire; there are alſo pits of it in Surry, and ſome other counties, and ſtrata in many places, where it would be very well worth the proprietors while to have it dug, though at preſent it is neglected.

It is of great uſe in ſcouring cloths, ſtuffs, &c. as it imbibes all the oil and greaſe uſed in dreſſing the wool.

FULLER'S WEED, in botany, a name ſometimes given to the dipſacus, or teaſel. See DIPSACUS.

FULLING, the art or act of ſcouring and preſſing cloths, ſtuffs, ſtockings, &c. to cleanſe, thicken, and render them more firm and ſtrong, which is done by means of a water-mill.

In the troughs of the mill are laid the cloths, ſtuffs, &c. intended to be fulled: then letting the current of water fall on the wheel, the mallets are ſucceſſively let fall upon them, when by their weight and velocity they ſtamp and preſs the ſtuffs very ſtrongly, which by this means become thickened and condenſed.

In this operation, fullers earth is uſed with ſome proportion of ſope; but ſope alone would do much better, was it not dearer than fuller's earth.

Fulling of ſtockings, caps, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or thoſe of horſes or bullocks. The ingredients generally uſed on this occaſion are fuller's earth, urine; white and green ſope; but water ſoftened with chalk is far preferable.

The following is M. Colmet's method of fulling with ſope, grounded on experiments made by order of the marquis de Louvois. Let a coloured cloth of about forty-five ells, be laid in the uſual manner in the trough of a fulling-mill, without firſt ſoaking it in water, as commonly practiſed in moſt places. To full this trough-full of cloth fifteen pounds of ſope are required, one half of which is to be melted into two pails of river or ſpring water, made as hot as the hand can bear. Let this ſolution be poured by little and little, upon the cloth, in proportion as it is laid in the trough: thus it is to be fulled for at leaſt two hours; after which, let it be taken out and ſtretched. This done, let the cloth be immediately returned into the ſame trough, without freſh ſope, and there fulled two hours more: then take it out, wring it well, and expreſs all the greaſe and filth. After the ſecond fulling, diſſolve the remainder of the ſope, as the former part, and throw it at four ſeveral times on the cloth, not forgetting to take it out every two hours, to undo the plaits and wrinkles it got in the trough. When it is ſufficiently fulled, and brought to the requiſite quality and thickneſs, it is ſcoured out for good in hot water, keeping it in the trough till it be thoroughly clean. As white cloths full more eaſily than coloured ones, a third part of the ſope may be ſaved.

FULLING-MILL, a machine for fulling cloth.

This machine will be better underſtood by the drawing on plate LXVI. *fig.* 5. than by the moſt accurate deſcription.

A, the great wheel moved by horſes. This turns the trundles B, C, D, and alſo thoſe marked E, F, G. Then E turns the cog-wheel H, with the axis I K, and the croſs-pieces L, L 1, 1, 1, &c. are pullies or rollers. M N, M N, are wooden beaters turning upon an axis paſſing through N, N. Whilſt the axis I K turns about, the end *l* ſlides along the pulley 1, and falling off, the part M ſtrikes againſt the cloth in the trough at O, O. The lantern F carries the cog-wheel P, and the cranks Q, Q, which work the pumps T, T, by help of the levers R S, R S, moveable about *a*. The trundle G carries the cog wheels V and W, and W carries the trundle X, with the piſton Y, which grinds the indigo in the veſſel C D, whence it flows into the veſſel Z. The *m*, *m*, &c. of all the axles run in pieces of timber going acroſs the mill, and faſtened to one another, and to the walls of the houſe.

FULMINATING, ſomething that thunders, or reſembles thunder. See the article THUNDER.

FULMINATION, in chemiſtry, is uſed in a ſynonymous ſenſe with detonation. See DETONATION.

FUMIGATION, in chemiſtry, a kind of calcination, when metals, or other hard bodies, are corroded, or ſoftened, by receiving certain fumes for that purpoſe.

FUMIGATION, in medicine, the application of fumes to particular parts of the body; as thoſe of factitious cinnabar to venereal ulcers.

FUMITORY, *Fumaria*, in botany, a plant with blueiſh green finely divided leaves; producing, towards the tops of the ſtalks, oppoſite to the leaves, ſpikes of irregular purpliſh flowers, followed each by a ſingle ſeed. It is an annual weed, growing in ſhady cultivated grounds, and flowers in May and June.

This herb is recommended as an aperient and reſolvent, in obſtructions of the viſcera, in ſcorbutic and cutaneous maladies. Hoffmann has a high opinion of it as a purifier of the blood, and gives it the preference to all the other herbs made uſe of in that intention. However, at preſent it is a ſtranger to practice; its ſenſible operation is by looſening the belly, and promoting urine.

FUNCTION, the act of fulfilling the duties of any employment.

Function is alſo applied to the actions of the body.

FUNCTION, in algebra, denotes any compound quantity; and when one of the component quantities is variable, it is ſaid to be a variable function. See the article QUANTITY.

FUND, in anatomy, ſignifies the bottom of any cavity

in the body; thus, the fund of the eye is that part poſſeſſed by the choroides and retina; the fund of the uterus, the fund of the bladder, &c. ſignify alſo the bottom of theſe parts. See the articles EYE and UTERUS.

FUND, in commerce, ſignifies the ſtocks of the great trading and monied companies. See the article STOCKS.

FUNDS is alſo a term adopted by thoſe who ſpeak of the public revenue of nations, to ſignify the ſeveral taxes that have been laid upon merchandizes either by way of duties of cuſtom, or exciſe, or in any other manner, to ſupply the exigencies of the ſtate, and to pay intereſt for what ſums it may have occaſion to borrow.

FUNERAL RITES, ceremonies accompanying the interment or burial of any perſon. See the article BURIAL.

FUNERAL COLUMN, a column crowned with an urn, wherein the aſhes of ſome deceaſed perſon are ſuppoſed to be encloſed; the ſuſt or ſhaft being beſet with tears or flames, the ſymbols of grief and immortality. See COLUMN.

FUNGUS, in ſurgery, a ſoft, fleſhy, ſpongy exceſcence, ariſing in the membranes, tendons, and other nervous parts, in conſequence of ulcers, wounds, contuſions, &c.

Mr. Sharp ſays, that in wounds made by a ſharp inſtrument, where there is no indiſpoſition of body, the cure is generally performed without any interruption but from the fungus; ſo that the buſineſs of ſurgery will conſiſt principally in a proper regard to that point, and the applications that will the leaſt interfere with the ordinary courſe of nature, which in theſe caſes will be ſuch as act the leaſt upon the ſurface of the wound; and, agreeable to this, we find that dry lint only is generally the beſt remedy through the whole courſe of dreſſing; at firſt it ſtops the blood with leſs injury than any ſtyptic powders or waters; and afterwards by abſorbing the matter, which in the beginning of ſuppuration is thin and acrimonious, it becomes, in effect, digeſtive: during incarnation, it is the ſofteſt medium that can be applied between the roller and tender granulations, and at the ſame time is an eaſy compreſs upon the ſprouting fungus.

If ulcers ſhould be of ſuch a nature as to produce a ſpongy lax fleſh ſprouting very high above the ſurface, it will be neceſſary to deſtroy it by ſome of the eſcharotics, or the knife: this fungus differs very much from that belonging to healing wounds, being more eminent and lax, and generally in one maſs; whereas the other is in little diſtinct protuberances. It approaches often towards a cancerous complexion; and when it riſes upon ſome glands, actually degenerates ſometimes into a cancer, as has happened in buboes of the groin. When theſe exceſcences have aroſe in venereal ulcers, eſcharotics are to be preferred; and pulvis angelicus, which is a compoſition of precipitate powder and burnt alum, as it eats deeper, is preferable to precipitate alone.

FUNGUS, in botany, an order of vegetables, extremely different from all others, and belonging to the cryptogamia claſs of Linnæus.

The fungi have, indeed, ſo little of the common and general appearance of vegetables, that many have denied them to be ſuch, and contended for their being only excrementitious matter, protruded from decaying vegetables of other kinds. But notwithſtanding the fungi have neither the colour or texture of other plants, nor leaves nor flowers like them; yet they muſt be allowed to belong to the vegetable kingdom, as having abſolute and perfect ſeeds, conſiſting uſually of ſingle antheræ, which produce plants like thoſe from which they are collected.

The fungi are extremely different in figure, and in their manner and place of growth; ſome growing on the ground, ſome on living trees, and many on decayed wood; and that horizontally or erect. Some are of only a few days duration, others remain for years, and ſome there are which grow under the ſurface of the earth in no particular direction.

FUNNEL *of a Chimney*, the ſhaft or ſmalleſt part of the waſte, where it is gathered into its leaſt dimenſions.

Palladio directs, that the funnels of chimneys be carried through the roof four or five feet at leaſt, that they may carry the ſmoke clear from the houſe into the air. See the article CHIMNEY.

He alſo adviſes, that chamber-chimneys be not made narrower than ten or eleven inches, nor broader than fifteen; for if too narrow, the ſmoke will not be able to make its way; and if too wide, the wind will drive it back into the room.

FUNNEL-FASHIONED, or FUNNEL-SHAPED-FLOWERS, in botany. See the article INFUNDIBULIFORM.

FUR, or FURR, in commerce. See FURR.

FURBISHER, a perſon who furbiſhes, poliſhes, or cleans arms, as guns, ſwords, piſtols, &c. which is chiefly performed with emery.

FURIES, *Eumenides*, *Diræ*, certain goddeſſes whoſe office it was to puniſh the guilty after death. Theſe were three in number; Alecto, Megæra, and Tiſiphone, who were deſcribed with ſnakes inſtead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to diſcover, and the former to puniſh the guilty; and they were ſuppoſed to be conſtantly hovering over ſuch perſons as had been guilty of any enormous crime.

Mythologiſts ſuppoſe, that Tiſiphone puniſhed the crimes which ſprang from hatred or anger; Megæra, thoſe from envy; and Alecto, thoſe from an inſatiable purſuit after riches and pleaſure. They were worſhipped at Caſina in Arcadia, and at Carmia in Peloponneſus. They had a temple at Athens, near the Areopagus, and their prieſts were choſen from amongſt the judges of that court. At Telphuſia a city in Arcadia, a black ewe was ſacrificed to them.

FURLING, in the ſea language, rolling a ſail up cloſe to the yard, ſtay, or maſt, and faſtening it by rolling a bandage or rope cloſe about it, and hence

FURLING-LINE is a line to faſten the ſail; thoſe which are made for yards are plaited and flat, and called gaſketts.

FURLONG, a long meaſure, equal to $\frac{1}{8}$ of a mile, or forty poles. See the articles MEASURE, MILE, and POLE.

It is alſo uſed in ſome law-books for the eighth part of an acre. See ACRE.

FURLOUGH, in the military language, a licence granted by an officer to a ſoldier, to be abſent for ſome time from his duty.

FURNACE, a veſſel or utenſil for maintaining a ſtrong fire, either of coal or wood.

FURNACE is alſo applied to that uſed in the melting of iron, which authors frequently confound with iron forges, though there is a conſiderable difference between them. See FORGE.

This furnace is a brick-ſtructure, much in the ſhape of an egg ſet on end, wherein the iron-ore, after it has been burnt in a kiln, is put, intermixed with cinders and charcoal, and the whole melted till it trickle down into the receiver underneath.

Swedenborg has laid down, from his own experience, certain rules for the conſtruction of metallurgic furnaces, by which they will always be made more advantageous to the proprietor, *cæteris paribus*, than any other kind. Theſe rules are, that the chimney be always placed as nearly as may be behind the center of the furnace; that the ſmaller the depth of the fire-place, provided it be ſufficient to hold the coals, the better; that all furnaces muſt be the better the wider they are forwards, and the higher they are, ſo as not to loſe the benefit of reverberation.

Bellows-FURNACE is one of the two kinds of furnaces uſed in coinage for the fuſion of metals, conſiſting of a flat hearth at bottom, into which the air may be admitted by a hole, as in the chemical furnace. On a level with the hearth is a ſecond aperture, which gives paſſage to the pipe of the bellows, from whence the furnace is denominated; about a foot over this is a moveable grate; and over this is the place where the crucible is ſet, which is ſquare, and made of the ſame earth with the crucible, of breadth ſufficient to bear a range of coals around the crucible. To melt metal in this furnace, they lay a little plate of forged iron over the grate, and on this they ſet the crucible, which is likewiſe covered with an iron or earthen lid; then they fill the furnace with charcoal, and when it is well lighted, and the crucible ſufficiently hot, they ſtop the vent-hole: laſtly, throwing on freſh coals, they ſtop the furnace with an iron lid; thus continuing

tinuing to work the bellows, and ſupply freſh fuel, till the metal is in fuſion.

Glaſs Painter's FURNACE is made of brick, nearly ſquare, and about 2 ½ feet each way. It is cut horizontally in the middle, by a grate, which ſuſtains the pan or ſhovel the glaſs is baked in. This furnace has two apertures, one below the grate, to put the fuel in at; the other above it, through which the workman ſpies how the action of the colours goes on.

Hatter's FURNACES are of three kinds: a little one under the mould, whereon they form their hats; a larger in the ſcouring-room, under a little copper, full of lees; and a very large one under the great copper, wherein they dye their hats.

Plumber's FURNACE is a receptacle for the melting of their metal for caſting ſheet lead, &c. It is made of caſt-iron, in the form of a common copper furnace; but by the plumbers called a pot, which is ſet up with brick in the ſame manner as that of copper.

Wind-FURNACE, the ſecond furnace uſed in the fuſion of metals for coinage. At bottom it has a hearth made hollow, in manner of a copel, with a vent-hole in the fore part thereof; over the vent-hole is a grate, ſealed in the maſſive of the furnace; over the grate is the place for the crucible, which is uſually of forged iron. The fire being lighted, the crucible is put in, with a cover over it, and a capital or cover of earth or iron, is laid likewiſe over the furnace; and at the top of this capital is a hole, five or ſix inches in diameter. This is called a wind-furnace, by reaſon the air entering thro' the vent-hole at bottom, which is always open, ſerves the ſame purpoſe as the bellows in the other furnaces. Gold is generally melted in the bellows-furnace, as requiring an intenſer heat before it fuſes; but ſilver and copper are commonly melted in the wind-furnace.

FURNITURE, in dialling, certain additional points and lines, ſuch as the ecliptic, circles of declination, azimuths, Italian hours, points of the compaſs, &c. drawn on dial-planes.

FUROR UTERINUS, a ſpecies of madneſs peculiar to women, proceeding from an ardent and inordinate deſire of coition, which deprives the patient of the uſe of reaſon, ſo that ſhe ſpeaks all manner of obſcene words, and abandoning all ſhame, invites the men to venereal embraces.

The immoderate deſire of copulation is produced by the plenty, acrimony, and heat of the uterine juices, exceeding the natural bounds, and creating an extraordinary turgency in the ſeminal veſſels, which, ſtimulating in a manner and inflaming the genital parts, excites a vehement and unruly appetite to venereal commerce.

FURR, in commerce, ſignifies the ſkin of ſeveral wild beaſts, dreſſed in alum with the hair on, and uſed as a part of dreſs by princes, magiſtrates, and others. The kinds moſt in uſe are thoſe of the ermine, ſable, caſtor, hare, rabbit, &c. See the articles ERMINE, SABLE, &c.

FURRS, in heraldry, a bearing which repreſents the ſkins of certain beaſts, uſed as well in the doublings of the mantles belonging to the coat-armour, as in the coat-armours themſelves. See the articles ERMINE, ERMINOIS, &c.

FURR, among carpenters, a piece nailed upon a raſter, to ſtrengthen it when decayed, or to make it ſtraight when it has ſunk in the middle.

FURRING, among carpenters, is the regular faſhioning out any part. When the main piece of the material is ſcanty, either by defects, wains, or want of thickneſs; then a piece of the ſame is put behind it to make good its thickneſs, which is called a furr.

FURUNCLE, or BOIL, in ſurgery, a ſmall reſiſting tumour, with inflammation, redneſs, and great pain, ariſing in the adipoſe membrane, under the ſkin.

As there is no part of the body free from being the ſubject of furuncles, ſo the whole is ſometimes ſo miſerably infeſted with them, that the patient can hardly tell how to ſtir himſelf, or on what part to lie. Not only adults, but alſo the younger, even new-born infants, are obnoxious to this dreadful diſorder, which occaſions in them moſt fatiguing clamour and reſtleſſneſs. Though there is little danger in this diſeaſe in adults; yet, in tender infants, it occaſions convulſions, and even death itſelf.

The principal cauſe of furuncles is a too glutinous and inſpiſſated ſtate of the blood; and, conſequently, the greater the inſpiſſation, the worſe and more numerous will be the furuncles.

With regard to the cure, it ſeems to conſiſt chiefly in reſtoring the ſtagnating blood to its former circulation and free motion.

When the furuncles are very numerous, or return again, it is proper to uſe internal purging medicines, and ſuch as attenuate and cleanſe the blood. In adults, bleeding is proper, both by the lancet and ſcarification with cupping; and, at the ſame time, a ſtrict regimen of diet ſhould be uſed, drinking frequently and plentifully of a decoction of the woods, and ſuch like attenuators of the blood. The patient ſhould alſo entirely abſtain from drinking fermented and ſpirituous liquors, particularly wine and its ſpirit; and from the too frequent uſe of tobacco. When the diſorder is recent, external medicines only will frequently ſuffice for the whole cure. For this purpoſe a mixture of honey, acidulated with ſpirit of vitriol till it has acquired a conſiderable ſharpneſs, is proper to anoint the furuncles. Of no leſs virtue is the frequent touching them with mere ſpirit of vitriol or ſulphur. Diſcutient plaſters are alſo found very ſerviceable, as thoſe of ſimple diachylon, de melito, de ſpermaceti, vel diaſaponis.

But if theſe medicines prove inſufficient to diſperſe the tumour, it is to be brought to ſuppuration, by applying a plaſter made of honey and flour, or of diachylon with the gums; and where theſe are inſufficient, to make uſe of the maturating cataplaſms recommended under the article PHLEGMON.

When the furuncle is known to be ripe, by its ſoftneſs and yellow head, recourſe is to be directly had to the ſcalpel; and having made an opening, the corrupted matter contained therein is to be diſcharged: after this, a plaſter of diachylon muſt be applied, and the ulcer daily cleanſed of its matter, till it is healed.

Puſtules and pimples ariſing in the face, are to be treated like furuncles; and, in both caſes, the drinking of whey, and the mineral waters, is accounted good for cleanſing the blood.

When ſucking infants are afflicted with furuncles, it is proper to give the mother, or nurſe, ſome purging medicine, and to order a ſtrict regimen and diet. At the ſame time the infant ſhould take ſome gentle laxative medicine, with abſorbent powders, to allay the acrimony of its juices. *Heiſter.*

FURZE, or FURZE-BUSH, in botany. See the article ULEX.

FUSAROLE, in architecture, a round member, carved in the manner of a collar or chaplet, with oval beads, and placed immediately under the echinus, in the Doric, Ionic, and Compoſite capitals.

FUSEE, in clock-work, is that conical part drawn by the ſpring, and about which the chain or ſtring is wound; for the uſe of which, ſee the articles CLOCK and WATCH.

FUSEE, or FIRELOCK. See MUSKETT.

FUSIBILITY, in natural philoſophy, that quality of bodies which renders them fuſible.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and ſharp than the other two in the middle. It is called in Latin, *fuſus*, a ſpindle, from its ſhape.

FUSILIERS, or FUSILEERS, in the military art, are foot ſoldiers, armed with fuſees, or firelocks. See the article FIRELOCK.

FUSILY, or FUSILE, in heraldry, ſignifies a field, or ordinary, entirely covered over with, or divided into, fuſils. See FUSIL.

FUSION, the melting of metals, minerals, &c. by means of fire.

Different metals run in different manners from their ores: thus, lead, though extremely fuſible in the metal, runs with difficulty from the ore, ſo as to require a conſiderable violence of fire. This ſtubbornneſs not belonging to the metal, muſt be attributed to the ſtony, ſulphureous, or other mineral matter with which the ore is mixed; which matter ſeems to require a degree of heat capable

capable of vitrifying the lead, before the metal will run: but then the lead thus vitrified, recovers a metallic form again, by coming in contact with the coals. See the article LEAD.

Tin runs from its ore with greater eaſe than lead, and is therefore melted in much leſs furnaces: but copper requires an intenſe heat, or a blaſt furnace; and iron the greateſt heat that can be given in a furnace: and both iron and copper abſolutely require immediate contact with the fuel employed. Hence it appears that each metal muſt have its determinate degree of heat, to run it with advantage from the ore or ſtone.

In order, likewiſe, to obtain the metal from the ore to the beſt advantage, the ſcoria or ſlag muſt be neceſſarily made to run thin and fluid; otherwiſe it entangles or inviſcates the metal, and will not let it ſeparate fully. And hence we frequently obſerve in the aſſaying of copper ores, ſmall grains of metal interſperſed here and there, among the ſcoria, that require to be ſeparated by ſtamping and waſhing the whole maſs; which labour might have been prevented, by uſing a proper degree of heat capable of procuring a thin fuſion and a ſuitable flux, ſo as to have made all the metals fall to the bottom of the crucible; which it conſtantly does, when the operation is well performed. See FLUX.

It ſeems principally owing to a defect in the knowledge of fuſion, that ſo many recrements or ſlags of metals, anciently thrown as uſeleſs from the furnace, have been of late wrought to conſiderable profit by more ſkilful workmen: at leaſt it ſeems more rational to attribute the ſucceſs to this cauſe, than to a ſuppoſed growth of metals in ſuch ſlags; or to believe that lead has grown rich in ſilver by lying expoſed to the open air, while perhaps it is rather owing to the unſkilfulneſs of the former workmen, who were unable to ſeparate all the ſilver contained in the lead.

All moiſture, and too ſudden cooling, prove prejudicial to the more ignoble metals after fuſion, and ſometimes dangerous to the operator: for a little water falling upon melted iron or copper, makes them expand with prodigious violence, and diſcharge themſelves abroad with a force like that of a cannon; and even ſudden cooling will often occaſion the ſurface of the metal to crack, and ſuffer the more internal part, not yet ſet or fixed, to iſſue out to a conſiderable diſtance; whence either the loſs of the metal or miſchief may enſue.

To prevent theſe ill effects, after copellation it is uſual for the operator to throw a quantity of water, all at once, upon the lump of ſilver, as it lies in the teſt, at the moment when it begins to grow rigid; for the water, by its coldneſs, ſuddenly makes ſo thick a cover upon the ſurface of the ſilver, that the hotter parts in the inſide cannot break through the upper. *Shaw's Chem. Lect.*

FUST, the ſame with the ſhaft of a column. See the articles COLUMN and SHAFT.

FUSTIAN, in commerce, a kind of cotton ſtuff which ſeems as it were whaled on one ſide.

Right fuſtians ſhould be altogether made of cotton yarn, both woof and warp; but a great many are made of which the warp is flax, or even hemp.

There are fuſtians made of ſeveral kinds, wide, narrow, fine, coarſe; with ſhag or nap, and without it.

FUSTICK, or FUSTOCK, a yellow wood, that grows in all the Caribbee-iſlands, uſed in dying yellow.

FUTTOCKS, in ſhip-building, that part of a timber which reaches from the floor to the top-timber. See this diſtinctly explained in the article TIMBER.

FUTTOCK-*Shrowds*. See the article *Futtock*-SHROWDS.

FUTURE, in general, denotes whatever regards futurity, or the time to come. See the article TIME.

FUTURE TENSE, among grammarians. See the article TENSE.

FUZEE, or FUSEE, in military affairs. See the article FUSEE.

FUZEE, among farriers, two dangerous ſplents, joining from above downwards. They differ from ſcrew or thorough ſplents in this, that the latter are placed on two oppoſite ſides of the leg. See the article SPLENT.

G.

GAG GAG

G in grammar, the ſeventh letter and fifth conſonant of our alphabet; but in the Greek, and all the oriental languages, it occupies the third place. It is one of the mutes, and cannot be ſounded without the aſſiſtance of ſome vowel.

In Engliſh it has a hard and ſoft ſound; hard, as in the words *game*, *gun*, &c. and ſoft, as in the words *geſture*, *giant*, &c. at the end of words, *gh* is pronounced like *ff*, as in the words *rough*, *tough*, &c. The letter *g* is alſo uſed in many words where the ſound is not perceived, as in *ſign*, *reign*, &c.

As a numeral, G was anciently uſed to denote 400; and with a daſh over it, thus $\overline{G}$, 40,000. In muſic it is the character or mark of the treble cleff; and from its being placed at the head, or marking the firſt ſound in Guido's ſcale, the whole ſcale took the name gamut. See the articles CLEF and GAMUT.

GABEL, a word met with in old records, ſignifying a tax, rent, cuſtom, or ſervice, paid to the king, or other lord.

GABEL, according to the French duties or cuſtoms, a tax upon ſalt, which makes the ſecond article in the king's revenue, and amounts to about one fourth part of the whole revenue of the kingdom.

GABIONS, in fortification, baſkets made of ozier-twigs, of a cylindrical form, ſix feet high, and four wide; which being filled with earth, ſerve as a ſhelter from the enemies fire.

They are commonly uſed on batteries, to ſcreen the engineers, &c. in order to which, one is placed on either ſide of each gun, room being only left for the muzzle to appear through. They alſo ſerve as a parapet on lines, lodgements, &c. when the ground is too hard to dig into.

There are a ſmaller ſort, uſed on parapets in trenches, &c. to cover the muſqueteers; which are placed ſo cloſe that the muzzle of a muſquet can hardly be put through.

GABLE, or GAVEL, among builders. See GAVEL.

GAD, among miners, a ſmall punch of iron, with a long wooden handle, uſed to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by ſtriking it with a ſledge hammer.

GAD-FLY, or BREEZE-FLY, names given to the black and yellow bodied œſtrus, a fly nearly as large as the common blue fleſh-fly. See OESTRUS.

GAFOLD-LAND, in old law-books, land liable to taxes, and let for rent.

GAGATES, JET, in natural hiſtory. See the article JET.

GAGE, in law-books, the ſame with ſurety or pledge. See the articles SURETY and PLEDGE.

GAGE, in joinery, an inſtrument marked G, in plate LXVII. *fig.* 1. in which the piece of wood *b* is moveable upon the ſtaff *c*, ſo as to be ſet nearer or farther from the tooth *a*, at pleaſure. Its uſe is to draw a line parallel to the ſtraight ſide of any board, for gaging tenons, and marking ſtuff for an equal thickneſs.

GAGE, among letter-founders, a piece of box, or other hard wood, variouſly notched; the uſe of which is to adjuſt the dimenſions, ſlopes, &c. of the different ſorts of letters. See *Letter* FOUNDERY.

Sliding-GAGE, a tool uſed by mathematical inſtrument makers, for meaſuring and ſetting off diſtances. It is alſo of uſe in letter-cutting, and making of moulds; ſee plate LXVII. *fig.* 2. where *aa* is the beam, *b* the tooth, *cc* the ſliding-ſocket, and *dddd* the ſhoulder of the ſocket.

GAGE, or *Weather*-GAGE, in navigation, a ſhip is ſaid to have gained the weather-gage of another when ſhe makes a greater progreſs to the windward, or when ſhe ſails to the windward of ſome other. See the article TACKING.

Sea-GAGE, an inſtrument invented by Dr. Hales and Dr. Deſaguliers, for finding the depth of the ſea, the deſcription of which is this. AB (plate LXVII. *fig.* 3.) is the gage-bottle, in which is cemented the gage-tube F*f* in the braſs cap at G. The upper-end of the tube F is hermetically ſealed, and the open lower-end *f* is immerſed in mercury, marked C, on which ſwims a ſmall thickneſs or ſurface of treacle. On the top of the bottle is ſcrewed a tube of braſs HG, pierced with ſeveral holes, to admit the water into the bottle AB. The body K is a weight hanging by its ſhank L, in a ſocket N, with a notch on one ſide at *m*, in which is fixed the catch *l* of the ſpring S, and paſſing through the hole L, in the ſhank of the weight K, prevents its falling out, when once hung on. On the top, in the upper part of the braſs-tube at H, is fixed a large empty ball, or full-blown bladder I, which muſt not be ſo large but that the weight K may be able to ſink the whole under water.

The inſtrument, thus conſtructed, is uſed in the following manner. The weight K being hung on, the gage is let fall into deep water, and ſinks to the bottom; the ſocket N is ſomewhat longer than the ſhank L, and therefore, after the weight K comes to the bottom, the gage will continue to deſcend, till the lower part of the ſocket ſtrikes againſt the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K; when this is done, the ball or bladder I, inſtantly buoys up the gage to the top of the water. While the gage is under water, the water having free acceſs to the treacle and mercury in the bottle, will by its preſſure force it up into the tube F*f*, and the height to which it has been forced by the greateſt preſſure, viz. that at the bottom, will be ſhewn by the mark in the tube which the treacle leaves behind it, and which is the only uſe of the treacle. This ſhews into what ſpace the whole air in the tube F*f* is compreſſed; and conſequently the height or depth of the water, which by its weight produced that compreſſion, which is the thing required.

If the gage-tube F*f*, be of glaſs, a ſcale might be drawn on it with the point of a diamond, ſhewing, by inſpection, what height the water ſtands above the bottom. But the length of 10 inches is not ſufficient for fathoming depths at ſea, ſince that, when all the air in ſuch a length of tube is compreſſed into half an inch, the depth of water is not more than 634 feet, which is not half a quarter of a mile.

If, to remedy this, we make uſe of a tube 50 inches long, which for ſtrength may be a muſquet-barrel, and ſuppoſe the air compreſſed into an hundredth part of half an inch; then by ſaying as 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But ſince it is reaſonable to ſuppoſe the cavities of the ſea bear ſome proportion to the mountainous parts of the land, ſome of which are more than three miles above the earth's ſurface; therefore, to explore ſuch great depths, the Dr. contrived a new form for his ſea-gage, or rather for the gage-tube in it, as follows: B C D F (*fig.* 4.) is a hollow metalline globe communicating on the top with a long tube A B, whoſe capacity is a ninth part of that globe. On the lower part at D, it has alſo a ſhort tube DE, to ſtand in the mercury and treacle. The air contained in the compound gage-tube is compreſſed by the water, as before; but the degree of compreſſion, or height to which the treacle has been forced, cannot here be ſeen thro' the tube; therefore, to anſwer that end, a ſlender rod of metal or wood, with a knob on the top of the tube A B, will receive the mark of the treacle, and ſhew it, when taken out.

If the tube A B be 50 inches long, and of ſuch a bore that every inch in length ſhould be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compreſſed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compreſs the air into half that ſpace nearly, viz. 2½ inches, which correſpond to 6600, which is a mile and a quarter. Again, half that ſpace, or 1¼ inch, will ſhew double the former depth, viz. 13200 feet, or 2½ miles, which is probably very nearly the greateſt depth of the ſea.

Bucket-Sea-GAGE, an inſtrument contrived by Dr. Hales, to find the different degrees of coldneſs and ſaltneſs of the ſea, at different depths; conſiſting of a common houſhold pail or bucket, with two heads to it. Theſe heads have each a round hole in the middle, near four inches diameter, and covered with valves opening upwards; and that they might both open and ſhut together, there is a ſmall iron-rod fixed to the upper part of the lower valve, and at the other end to the under part of the upper valve; ſo that as the bucket deſcends with its ſinking weight into the ſea, both the valves open by the force of the water, which by that means has a free paſſage through the bucket. But when the bucket is drawn up, then both the valves ſhut by the force of the water at the upper part of the bucket; ſo that the bucket is brought up full of the loweſt ſea-water to which it had deſcended.

When the bucket is drawn up, the mercurial thermometer, fixed in it, is examined; but great care muſt be taken to obſerve the degree at which the mercury ſtands, before the lower part of the thermometer is taken out of the water in the bucket, elſe it would be altered by the different temperature of the air.

In order to keep the bucket in a right poſition, there are four cords fixed to it, reaching about four feet below it, to which the ſinking weight is fixed.

Water-GAGE, or HYDROMETER. See the article HYDROMETER.

GAIANITES, *Gaianitæ*, in church hiſtory, a branch of Eutychians. See EUTYCHIANS.

GAIN, in commerce, is uſed in a ſynonymous ſenſe with profit. See PROFIT.

GAIN, in architecture, the levelling ſhoulder of a joiſt or other timber.

It is alſo uſed for the lapping of the end of the joints, &c. upon a trimmer or girder, and then the thickneſs of the ſhoulder is cut into the trimmer, alſo levelling upwards, that it may juſt receive the gain, and ſo the joiſt and trimmer lie even and level with the ſurface.

This way of working is uſed in floors and hearths.

GALANGALS, *Galanga*, in the materia medica, the name of two roots kept in the ſhops, a greater and a ſmaller; of which the ſmaller is by far the moſt eſteemed.

The leſſer galangal is a ſmall and ſhort root, of an irregular figure, and of the thickneſs of a man's little finger ſeldom met with more than an inch or two long. I ſhould be choſen full and plump, of a bright colour, ver firm and ſound, and of an acrid and inſupportably ho taſte.

The larger galangal is brought to us in pieces of tw inches or a little more in length, and of near an inch i thickneſs: its ſurface is leſs unequal and tuberoſe tha the ſmaller ſort, but is far from being ſmooth; on th outſide it is of a brown colour, with a very faint caſt red, and within it is of a paler colour, and has a muc leſs acrid and pungent taſte than the ſmaller kind. It to be choſen in the largeſt, ſoundeſt, and heavie pieces.

The roots of both the galangals, but particularly of th leſſer, abound with a volatile, oily, aromatic ſalt; th leſſer is eſteemed an excellent ſtomachic: it has the cred of being a great cephalic, cardiac, and uterine, but more particularly recommended in vertigos. Th greater galangal poſſeſſes the ſame virtues, but in a le degree.

GALANTHUS, the ſnow-drop, in botany, a genu of plants, the flower of which conſiſts of three oblon and obtuſe petals; the fruit is a globoſo-oval capſul obtuſely trigonal, and containing a great number roundiſh ſeeds.

The galanthus is the ſame with the narciſſo-leucoiu of authors, with a large ſnow-white flower.

GALAXY, in aſtronomy, the via lactea, or milk way in the heavens: a tract of a whitiſh colour, a conſiderable breadth, which runs thro' a great compa of the heavens, ſometimes in a double, but for the grea eſt part of its courſe in a ſingle ſtream; and is compoſe of a vaſt number of ſtars, too minute or too remote fro the earth, to be diſtinguiſhed by the naked eye; but a diſcovered in all parts of it, in great numbers, by t aſſiſtance of the teleſcope.

GALBANUM, in pharmacy, a gum iſſuing from t ſtem of an umbelliferous plant, growing in Perſia a many parts of Africa.

It is ſometimes met with in the ſhops in looſe gr nules, called drops or tears, and ſometimes in lar maſſes, formed of a number of theſe blended togethe but in theſe maſſes ſome accidental foulneſs is often mix with the gum. The ſingle drops uſually approach a roundiſh, oblong, pear-like form. Galbanum is ſo like wax, and, when freſh drawn, white; but it afte wards becomes yellowiſh or reddiſh: it is of a ſtro ſmell, of an acrid and bitteriſh taſte; it is inflammab in the manner of a reſin, and ſoluble in water like gum.

It attenuates and diſſolves tough phlegm, and is the fore of ſervice in aſthmas and inveterate coughs: it alſo of great ſervice in hyſteric complaints; it diſſipa flatulencies, promotes the menſes, and facilitates delive and the expulſion of the ſecundines. It is given in p and electuaries, and is uſed externally in form of a plaſt applied to the belly, againſt habitual hyſteric co plaints, and on many other occaſions.

GALENIC, or GALENICAL, in pharmacy, a ma ner of treating diſeaſes founded on the principles Galen.

The diſtinction of galenical and chemical was oc ſioned by a diviſion of the practitioners of medicine i two ſects, which happened on the introduction of c miſtry into medicine; then the chemiſts arrogating themſelves every kind of merit and ability, ſtirred up oppoſition to their pretenſions, founded on the invari adherence of the other party to the antient practice. A though this diviſion into the two ſects of galeniſts chemiſts has long ceaſed, yet the diſtinction of medici which reſulted from it, is ſtill retained.

Galenical medicines are thoſe which are formed b eaſier preparations of herbs, roots, &c. by infuſion, de tion, &c. and by combining and multiplying ingredi while thoſe of chemiſtry draw their more intimate remote virtues by means of fire and elaborate prep ons, as calcination, digeſtion, fermentation, &c.

GALENISTS, in church hiſtory, a branc anabaptiſts, who are ſaid to have adopted ſ

Arian opinions concerning the divinity of our Saviour.

GALILEANS, a ſect of Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, eſteeming it an indignity for the Jews to pay tribute to ſtrangers, raiſed up his countrymen againſt the edict of the emperor Auguſtus, which had ordered a taxation or enrollment of all the ſubjects of the Roman empire.

They pretended that God alone ſhould be owned as maſter and lord; and in other reſpects were of the opinion of the Phariſees: but as they judged it unlawful to pray for infidel princes, they ſeparated themſelves from the reſt of the Jews, and performed their ſacrifices apart.

GALL, in the animal œconomy, the ſame with bile. See BILE and BILIOUS.

GALL-BLADDER, called veſicula, and cyſtis fellea, is uſually of the ſhape of a pear, and of the ſize of a ſmall hen's egg. It is ſituated in the concave ſide of the liver, and lies upon the colon, part of which it tinges with its own colour. It is compoſed of four membranes, or coats; the common coat; a veſicular one; a muſcular one, conſiſting of ſtraight, oblique, and tranſverſe fibres; and a nervous one, of a wrinkled or reticulated ſurface within, and furniſhed with an unctuous liquor.

The uſe of the gall-bladder is to collect the bile, firſt ſecreted in the liver, and mixing it with its own peculiar produce, to perfect it farther, to retain it together a certain time, and then to expel it.

GALL, in natural hiſtory, denotes any protuberance or tumour produced by the puncture of inſects on plants and trees of different kinds.

Theſe galls are of various forms and ſizes, and no leſs different with regard to their internal ſtructure. Some have only one cavity, and others a number of ſmall cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilſt others are ſoft and ſpongy; the firſt being termed gall-nuts, and the latter berry-galls, or apple-galls.

The general hiſtory of galls is this: an inſect of the fly-kind is inſtructed by nature to take care for the ſafety of her young, by lodging her eggs in a woody ſubſtance, where they will be defended from all injuries: ſhe for this purpoſe wounds the branches of a tree; and the lacerated veſſels, diſcharging their contents, ſoon form tumours about the holes thus made. The hole in each of theſe tumours, through which the fly has made its way, may for the moſt part be found; and when it is not, the maggot-inhabitant or its remains are ſure to be found within, on breaking the gall. However, it is to be obſerved, that in thoſe galls which contain ſeveral cells, there may be inſects found in ſome of them, though there be a hole by which the inhabitant of another cell has eſcaped.

Oak-galls put, in a very ſmall quantity, into a ſolution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows ſtronger, becomes black; and on this property depends the art of making our writing-ink, as alſo a great deal of thoſe of dying and dreſſing leather, and other manufactures.

In medicine, galls are found to be very aſtringent, and good, under proper management, in diarrhœas, dyſenteries, and hæmorrhages of all kinds; they have alſo a very eminent virtue as a febrifuge. Half a dram, or more, of the powder of Aleppo-galls may be given for a doſe, and will often cure an intermittent fever. They are alſo uſed externally by way of fomentation in procidentiæ of the anus: and a decoction of them has been injected in the fluor albus, with very great ſucceſs.

GALLEASSES, in the marine, the largeſt ſort of armed veſſels next to ſhips of war: they are a ſort of ſhip of one deck and three maſts; and are uſed by the Venetians only: they have thirty-two banks of oars, with ſix or ſeven ſlaves to an oar; three batteries of guns from thirty-ſix to twenty-four pounders; their complement of men conſiſts of a thouſand or twelve hundred. To ſee one of theſe galleaſſes at ſea, ſhe appears like a great floating iſland, able in appearance to encounter with twenty galleons (ſee the next article). The Turks have ſhips not unlike them, which they call mahones.

GALLEON was formerly a name given to ſhips of war which had three or four decks. That name is now no longer in uſe but with the Spaniards, which they give to their ſhips that are deſtined for Weſt-India voyages. Theſe ſhips, which are of a larger ſize, have always four decks. They give alſo the ſame name to greater or ſmaller veſſels, which go yearly to La Vera Cruz. The Portugueſe have ſhips which they call caragues, ſomewhat reſembling the galleon, which they ſend to India and the Brazils.

GALLERY *of a Ship*, a ſort of railed balcony, without the cabin, at the ſtern or quarter of a ſhip, for the convenience of the commander.

GALLERY, in architecture, a covered place in a houſe, much longer than broad, and uſually in the wings of a building; its uſe being chiefly to walk in.

GALLERY, in fortification, a covered walk acroſs the ditch of a town, made of ſtrong beams, covered over head with planks, and loaded with earth: ſometimes it is covered with raw hides to defend it from the artificial fires of the beſieged. Its ſides ſhould be muſket proof. It ought to be eight foot high, and ten or twelve wide, and the covering to riſe with a ridge, that what is thrown upon it by the beſiegers with a deſign to burn it, may roll off.

Galleries are chiefly uſed to ſecure and facilitate the miners approach to the face of the baſtion, over the moat, which is already ſuppoſed to be filled up with faggots and bavins, and the artillery of the oppoſite flank diſmounted.

GALLERY *of a Mine*, is a narrow paſſage, or branch of a mine, carried on underground to a work deſigned to be blown up.

Both the beſiegers, and the beſieged alſo, carry on galleries in ſearch of each other's mines, and theſe ſometimes meet and deſtroy each other.

GALLERY, in gardening, a kind of covered walk, in a garden, formed into porticoes or arches, with horn-beams, lime-trees, or the like.

Each pillar of the porticoes or arches ought to be four feet diſtant from the other, and the gallery twelve feet high, and ten feet wide, that there may be room for two or three perſons to walk in a-breaſt.

In forming theſe galleries, it is to be obſerved, that when the horn-beams are grown to the height of three feet, and the diſtance of the pillars well regulated; the next thing to be done is, to form the frontiſpiece: to perform which, the horn-beam muſt be run up a trellace made for that purpoſe, which forms the arch, and as it grows up, thoſe boughs which out-ſhoot the others, muſt be cut with the ſheers, and in time they will grow ſtrong, and may be kept in form by the ſheers.

GALLEY, a kind of low flat-built veſſel, with one deck, made either to ſail or row: they are from an hundred and twenty, to an hundred and thirty feet long, eighteen feet broad, and nine or ten feet deep. They have two maſts which can be ſtruck at pleaſure, two lateen ſails, and five pieces of cannon. The galleys have commonly twenty-five or thirty banks of oars on either ſide, to each of which are chained five or ſix ſlaves. There are no galleys now but in the Mediterranean; they commonly keep cloſe along ſhore; though they ſometimes venture out to ſea for a ſhort cruize.

GALLIAMBIC VERSE, *Galliambus*, in ancient poetry, a verſe conſiſting of ſix feet, viz. an anapeſt, or a ſpondee; an iambus, or an anapeſt, or a tribrach; an iambus; a dactyl; a dactyl; an anapeſt.

The word galliambus is a compound of iambus and gallus, a prieſt of Cybele. Theſe prieſts carried about the image of that goddeſs, in order to get alms, and as a part of their employment was ſinging verſes all over the country, they, by this means, rendered poetry very deſpicable.

GALLI, in antiquity, the prieſts of the goddeſs Cybele, who were eunuchs, and took their name from Gallus, a river in Phrygia.

GALLICAN, any thing belonging to France: thus the term Gallican church denotes the church of France, or the aſſembly of the clergy of that kingdom. See CHURCH.

GALLINÆ, in ornithology, an order of birds, the beak

beak of which is conic, and ſomewhat incurvated, and the upper chap imbricated.

Under this order are comprehended the oſtrich, peacock, pheaſant, woodcock, turkey, the common dunghill cock, partridge, &c.

GALLINACEOUS, an appellation given to the birds of the order of the gallinæ.

GALLING, or EXCORIATION, in medicine. See EXCORIATION.

GALLING *of a Horſe's Back*, a diſorder occaſioned by heat, and the chafing or pinching of the ſaddle.

In order to prevent it, ſome take a hind's ſkin well garniſhed with hair, and fit it neatly under the pannel of the ſaddle, ſo that the hairy ſide may be next the horſe.

When a horſe's back is galled upon a journey, take out a little of the ſtuffing of the pannel over the ſwelling, and ſew a piece of ſoft white leather on the inſide of the pannel; anoint the part with ſalt butter, and every evening wipe it clean, rubbing it till it grow ſoft, anointing it again with butter, or for want of that, with greaſe: waſh the ſwelling, or hurt, every evening with cold water and ſope, and ſtrew it with ſalt, which ſhould be left on till the horſe be ſaddled in the morning.

GALLIUM, ladies-bedſtraw, in botany, a genus of plants, the flower of which is a quadrifid ſingle petal, without any tube, and placed flatwiſe: the fruit conſiſts of two globoſe bodies, growing cloſe together, but not adhering, and containing each a ſingle kidney-ſhaped ſeed. It is ſaid to be an excellent aſtringent.

GALLON, a meaſure of capacity both for dry and liquid things, containing four quarts; but theſe quarts, and conſequently the gallon itſelf, are different, according to the quality of the thing meaſured: for inſtance, the wine gallon contains 231 cubic inches, and holds eight pounds averdupois, of pure water: the beer and ale gallon contain 282 ſolid inches, and holds ten pounds three ounces and a quarter averdupois, of water; and the gallon for corn, meal, &c. 272 $\frac{1}{4}$ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOON, in commerce, a narrow thick kind of ferret, or lace, uſed to edge or border cloaths, ſometimes made of wool, and at others of gold or ſilver.

GALLOP, in the manege, a motion of a horſe that runs at full ſpeed, in which making a kind of leap forewards, he lifts both his fore-legs almoſt at the ſame time; when theſe are in the air, juſt upon the point of touching the ground, he lifts both his hind-legs almoſt at once.

GALLOWS *of a Plough*, a part of the plough-head, ſo called by farmers, from its reſemblance to the common gallows, as conſiſting of three pieces of timber, whereof one is placed tranſverſely over the heads of the other two. See PLOUGH.

GALLUS, the COCK, in ornithology, a well known domeſtic fowl, the head of which is ornamented with a longitudinal fleſhy creſt, or comb: the wattles are two, and placed longitudinally on the throat. This, in its natural ſtate, is a very robuſt and beautiful bird, variegated with a great number of elegant colours.

GALLY, in printing, a frame into which the compoſitor empties the lines out of his compoſing ſtick, and in which he ties up the page when it is completed.

The gally is formed of an oblong ſquare board, with a ledge on three ſides, and a groove to admit a falſe bottom, called a gally-ſlice.

GAMBOGE is a concreted vegetable juice, the produce of two trees, both called by the Indians caracapulli, and is partly of a gummy, and partly of a reſinous nature. It is brought to us either in form of orbicular maſſes, or of cylindrical rolls of various ſizes; and is of a denſe, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the Eaſt-Indies, called alſo Cambodja, and Cambogia; and from thence it has obtained its names of cambadium, cambogium, and gambogium.

It is a very rough and ſtrong purge; it operates both by vomit and ſtool, and both ways with much violence, almoſt in the inſtant in which it is ſwallowed; but yet without griping. It requires caution and judgment in adminiſtring it; but thoſe who know how to give it properly, find it an excellent remedy in dropſies, cachexies, jaundice, aſthmas, catarrhs, and in the worſt cutaneous eruptions.

Its doſe is from two or three grains to ſix, eight, or ten; four grains generally operate briſkly without vomiting, and eight or ten grains uſually vomit briſkly, and afterwards purge downwards.

It is at preſent much more eſteemed by painters in water-colours, than by phyſicians.

GAME, *Ludus*, in general, ſignifies any diverſion, or ſport, that is performed with regularity, and reſtrained to certain rules. See the article GAMING.

GAMES, *Ludi*, in antiquity, were public diverſions exhibited on ſolemn occaſions. Such, among the Greeks, were the Olympic, Pythian, Iſthmian, Nemæan, &c. games; and, among the Romans, the Apollinarian, Circenſian, Capitoline, &c. games. See the articles OLYMPIC, PYTHIAN, &c.

GAMELIA, γαμηλια, in Grecian antiquity, a nuptial feaſt, or rather ſacrifice, held in the ancient Greek families on the day before marriage; thus called, from a cuſtom they had of ſhaving themſelves on this occaſion, and preſenting their hair to ſome deity to whom they had particular obligations.

GAMELION, a poem or compoſition in verſe on the ſubject of a marriage, commonly called epithalamium. See EPITHALAMIUM.

GAMING, the art or act of performing or practiſing a game, particularly a game of hazard, and this generally for ſtakes or a ſum of money.

Hazard, or chance, is a matter of mathematical conſideration, becauſe it admits of more and leſs. Gameſters either ſet out upon an equality of chance, or are ſuppoſed to do ſo. This equality may be altered, in the courſe of the game, by the greater good fortune or addreſs of one of the gameſters, whereby he comes to have a better chance, ſo that his ſhare in the ſtakes is proportionably better than at firſt. This more and leſs runs through all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinite great one, whereby the game is determined. The whole game, therefore, with regard to the iſſue of it, is a chance of the proportion the two ſhares bear to each other.

The probability of an event is greater or leſs, according to the number of chances by which it may happen, compared with the number of all the chances by which it may either happen or fail.—Thus, ſuppoſe p the number of chances whereby an event may happen, and q the number of chances whereby it may fail: then if two gameſters, A and B, engage on theſe terms, that if any of the chances p happen, A ſhall win; but if thoſe of q happen, B ſhall win; and the ſtake be a, the expectancy of A will be defined by $\frac{p}{p+q} \times a$, and that of B by $\frac{q}{p+q} \times a$; conſequently if A or B ſell their expectances, they ſhould receive for them $\frac{p}{p+q} \times a$, and $\frac{q}{p+q} \times a$, reſpectively.

If there be two independent events, and p the number of chances, or, which is the ſame thing, the number of caſes wherein the firſt may happen, and q the number of thoſe wherein it may not happen, and r the number of caſes wherein the ſecond event may happen, and s the number of thoſe wherein it may not happen: multiply $p+q$ by $r+s$; the product, viz. $pr+qr+ps+qs$, will be the number of caſes wherein the contingency or non-contingency of the events may be varied.

Hence, if A lay with B, that both events ſhall happen, the ratio of the chances will be as pr to $qr+ps+qs$; if he lay that the firſt ſhall happen, but not the ſecond, the ratio of the chances will be as ps to $pr+qr+qs$; and if there were three or more events, the ratio of the chances would be found by multiplication alone.

If all the events have a given number of caſes wherein they may happen, and alſo a given number of caſes wherein they may not; and a be the number of caſes wherein any one may happen, and b the number of caſes wherein

it may not; and n be the number of all the events; raiſe $a+b$ to the power of n. If now A and B agree, that if one or more of the events happen, A ſhall win; if none, B: the ratio of the chances will be as $\overline{a+b}^n - b^n$ to b^n; for the only term where a is not found, is b^n.

If A and B play with a ſingle die, on this condition, that if A throw two or more aces at eight throws, he ſhall win; otherwiſe B ſhall win; what is the ratio of their chances?—Since there is but one caſe wherein an ace may turn up; and five where may it not; let $a=1$, and $b=5$. And again, ſince there are eight throws of the die, let $n=8$, and you will have $\overline{a\times b}^n - b^n - nab^{n-1}$, to $b^n + nab^{n-1}$. That is, the chance of A will be to that of B, as 663991 to 1015625, or nearly as 2 to 3.

A and B are engaged at ſingle quoits, and after playing ſome time, A wants 4 of being up, and B, 6; but B is ſo much the better gameſter, that his chance againſt A upon a ſingle throw, would be as 3 to 2; What is the ratio of their chances?—Since A wants 4, and B, 6, the game muſt neceſſarily end in 9 throws at moſt; therefore raiſe $a+b$ to the ninth power, and it will be $a^9 + 9a^8b + 36a^7b^2 + 84a^6b^3 + 126a^5b^4 + 126a^4b^5 + 84a^3b^6 + 36a^2b^7 + 9ab^8 + b^9$: and all the terms wherein a has 4 or more dimenſions, are for A; and all thoſe wherein it has 6 or more, for B: and the ratio of the chances will be as $a^9 + 9a^8b + 36a^7b^2 + 84a^6b^3 + 126a^5b^4 + 126a^4b^5$, to $84a^3b^6 + 36a^2b^7 + 9ab^8 + b^9$. Call a, 3, and b, 2; and you will have the ratio of the chances in numbers, 1759077 to 194048.

A and B are to play at ſingle quoits; and A is the beſt gameſter; ſo that he can give B, 2 in 3: What is the ratio of their chances, then, in a ſingle throw?—Suppoſe the chances ſought to be as z to 1; raiſe $z+1$ to its cube, and it will be z^3+3z^2+3z+1. Now ſince A could give B 2 in 3, it is plain that A might undertake to win three throws running; and conſequently the chances in this caſe will be as z^3 to $3zz+3z+1$; therefore $z^3 = 3zz+3z+1$. Or, $2z^3 = z^3+3zz+3z+1$. And hence $\sqrt[3]{2}\times z = z+1$; conſequently $z = \frac{1}{\sqrt[3]{2}-1}$.

The chances therefore are $\frac{1}{\sqrt[3]{2}-1}$ and 1 reſpectively.

To find in how many trials it is probable any event will happen; ſo that A and B may lay a wager upon even terms.—Let the number of caſes, wherein the thing may happen at the firſt trial be a, thoſe wherein it may not, b; and x the number of trials, wherein it is an even chance, whether the thing happen or not. By what is ſhewn above $\overline{a+b}^x - b^x = b^x$. Or $\overline{a+b}^x = 2b^x$. Therefore $x = \frac{\text{log. } 2.}{\text{log. } a+b - \text{log. } b.}$

Again, reſume the equation $\overline{a+b}^x = 2b^x$, and let $a:b::q:1$, and the equation will change into this $\overline{1+q}^x = 2$. Raiſe $1+q$ to the power of x, and it will be $1+\frac{x}{q}+\frac{x}{1}\times\frac{x-1}{2qq}+\frac{x}{1}\times\frac{x-1}{2}\times\frac{x-2}{3q^3}$, &c. $=2$. In this equation, therefore, if $q=1$, then $x=1$; if q be infinite, x will alſo be infinite. Suppoſing x infinite, the equation above will become $1+\frac{x}{q}+\frac{x^2}{2qq}+\frac{x^3}{6q^3}$, &c. $=2$.

Again, let $\frac{x}{q}=z$, and we ſhall have $1+z+\frac{zz}{2}+\frac{z^3}{6}$, &c. $=2$. But $1+z+\frac{zz}{2}+\frac{z^3}{6}$, &c. is a number whoſe hyperbolical logarithm is z; conſequently $z=$log. 2. But the hyperbolical of 2 is ,7 nearly; and therefore $z = \frac{7}{10}$ nearly.

Hence, where q is 1, there $x=q$; and where q is infinite, $x = \frac{7}{10}$ of q nearly. Thus are the limits of the ratio of x to q fixed; for that ratio begins with equality, and when raiſed to infinity, ends at length in the ratio of 7 to 10 nearly.

To find in how many throws A may undertake to throw two aces with two dice?—Since A has but one caſe or chance wherein he may throw two aces with two dice; and 35 wherein he may not; $q=35$; therefore multiply 35 by ,7; the product 24,5, ſhews that the number of throws required is between 24 and 25.

To find the number of chances for throwing any given number of points with a given number of dice?—Let $p+1$ be the given number of points; n the number of dice, and f the number of faces upon each die: let $p-f=q$, $q-f=r$, $r-f=s$, $s-f=t$, &c. The number of chances required will be,

$$+\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3}, \text{ &c.}$$
$$-\frac{q}{1}\times\frac{q-1}{2}\times\frac{q-2}{3}, \text{ &c.}\times\frac{n}{1}$$
$$+\frac{r}{1}\times\frac{r-1}{2}\times\frac{r-2}{3}, \text{ &c.}\times\frac{n}{1}\times\frac{n-1}{2}$$
$$-\frac{s}{1}\times\frac{s-1}{2}\times\frac{s-2}{3}, \text{ &c.}\times\frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3}$$

Which ſeries is to be continued till ſome of the factors either become equal to nothing, or negative. And note, ſo many factors of the ſeveral products $\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3}$, &c. $\frac{q}{1}\times\frac{q-1}{2}\times\frac{q-2}{3}$, &c. are to be taken as there are units in $n-1$.

Thus for example, let it be required to find how many chances there are for throwing 16 points with four common dice; then making $p+1=16$, we have $p=15$; from whence the number of chances required will be found to be

$$+\tfrac{15}{1}\times\tfrac{14}{2}\times\tfrac{13}{3} = +455$$
$$-\tfrac{9}{1}\times\tfrac{8}{2}\times\tfrac{7}{3}\times\tfrac{4}{4} = -336$$
$$\tfrac{1}{1}\times\tfrac{2}{2}\times\tfrac{1}{3}\times\tfrac{4}{4}\times\tfrac{3}{4} = +\ 6$$

But $455-336+6=125$, and therefore one hundred and twenty-five is the number of chances required.

To find at how many caſts A may undertake to throw 15 points with ſix dice?—Since A has 1666 chances for bringing up 15 points, and 44990 againſt it, divide 44990 by 1666, and the quotient 27 will be $=q$; therefore multiply 27 by ,7, the product 18,9 ſhews the number of throws required to be nearly 19.

To find the number of trials wherein it is probable any event may happen twice; ſo that A and B may lay a wager thereon with an equal chance.—Suppoſe the chances for happening in the firſt trial, to be a, and thoſe for failing b, and call the number of trials required, x; it appears from what is above ſhewn, that $\overline{a+b}^x = 2bx + 2xbx^{-1}a$, or $1+px = \overline{\frac{1+p}{2}}^x$ by writing p for $\frac{a}{b}$; conſequently log. $\overline{1+px} = x\times$ log. $\overline{1+p}$ − log. 2. Now, for px ſubſtitute $2+v$, then log. $\overline{v+3} = \frac{2+v}{p}\times$ log. $\overline{1+p}$ − log. 2. It appears, by page 679 of Mac Laurin's Fluxions, that the log. of $m+z$ is nearly equal to $\frac{2z}{2m+z}$ + log. m; therefore, by ſubſtituting 3 for m, and v for z, on the left hand ſide of the above equation, and 1 for m, p for z on the right, we ſhall have $\frac{2v}{6+v}$ + log. $3 = \frac{2+v}{p}\times\frac{2p}{2+p}$ − log. 2, or becauſe p is very ſmall $\frac{2v}{6+v}$ + log. $3 = 2+v$ − log. 2, or $\frac{2v}{6+v} = 2+v$ − log. 6; for log. of 6 put 1,7971, reduce the equation by compleating the ſquare, &c. and we get $v=-,3266$, $2+v=1,6784=px$. If $a=b$, then $px=3$. Now as twice the former value of px, viz. 3,3568 exceeds 3, the latter by ,3568, it follows, that the value of x is nearly equal to $\frac{b}{a}\times\overline{2-,3568}+2-,6632$, or $\frac{b}{a}$ 1,64 + 1,33.

If the wager be upon happening once, the number of trials will be between 1 p and 0,693 p
If upon twice, between 3 p and 1,678 p
If upon thrice, between 5 p and 2,675 p
If upon four times, between 7 p and 3,671 p
If upon five times, between 9 p and 4,673 p
If upon ſix times, between 11 p and 5,668 p.

To find at how many throws A may undertake to throw three aces twice with three dice? Since A has but one chance for throwing three aces and 215 againſt it; $p=215$. Therefore, multiply 215 by 1,678, the product 360,7 will ſhew the number of throws required to be between 360 and 361.

A and B depoſit each 12 pieces of money, and play with three dice, on theſe conditions, that every time 11 points are thrown, A ſhall give B one piece, and every

time 14 points are thrown, B ſhall give A a piece; and that he ſhall win the whole, that firſt gets all the money in his hands: we demand the ratio of the chance of A to that of B?—Let p be the number of pieces each ſeverally ſtakes, and a and b the number of chances whereby A and B may reſpectively gain each a piece; the ratio of their chances will be as a^p to b^p. In this caſe $p=12$, $a=27$, $b=15$; or if when $27:15::9:5$, you make $a=9$, $b=5$; and therefore the ratio of the expectancies will be as 9^{12} to 5^{12}, or as 244140625 to 282429536481.

Note. Great care muſt be taken to avoid the confounding of different problems together, from ſome appearance of affinity between them. The following one ſeems very like the former. C having 24 pieces, or counters, throws three dice, and every time 27 points turn up, gives one counter to A, and every time 14 turns up, gives one to B; and A and B engage on this footing, that he who firſt gets 12 counters, ſhall win the ſtake; we require the ratio of their expectancies?—This problem differs from the preceding one, in that the game muſt neceſſarily end in 23 throws; whereas, in the former, it might continue without limitation, by reaſon of the reciprocations of loſs and gain, which deſtroy one another. —Raiſe $a+b$ to the 23^d power, and the 12 former terms will be to the 12 latter, as the expectancy of A to that of B.

Three gameſters, A, B, and C, have each 12 balls, 4 of them white, and 8 black; and, being hoodwinked, play on this condition, that the firſt who chooſes a white ball ſhall win the ſtake; and that A ſhall have the firſt choice, then B, then C; and ſo round again: What then is the ratio of the chances of A, B, C? Let n be the number of balls, a the number of white ones, b of black ones, and 1 the ſtake. Here,

1°. A has the chances a for taking a white ball; and the chances b for a black one; conſequently his expectancy from the firſt choice is $\frac{a}{a+b}$, or $\frac{a}{n}$; therefore the expectation he has upon the ſtake 1, ariſing from the circumſtance he is in when he begins to draw, is $\frac{a}{n}\times 1$, or $\frac{a}{n}$; let it therefore be agreed among the adventurers, that A ſhall have no choice for a white counter, but that he ſhall be reputed to have had a black one, which ſhall actually be taken out of the heap, and that he ſhall have the ſum $\frac{a}{n}$ paid him out of the ſtake for an equivalent. Now $\frac{a}{n}$ being taken out of the ſtake, there will remain $1-\frac{a}{n}$ or $\frac{b}{n}$.

2°. B's probability of winning is $\frac{a}{n-1}$, whence his expectation will be $\frac{ab}{n.n-1}$. Suppoſe it therefore agreed that B ſhall have the ſum $\frac{n.n-1}{ab}$ paid him out of the ſtake, and that a black ball ſhall alſo be taken out of the heap. This being done, the remaining ſtake will be $\frac{b}{n}-\frac{ab}{n.n-1}$ or $\frac{nb-b-ab}{n.n-1}$, but $nb-ab=bb$; wherefore the remaining ſtake is $\frac{b.b-1}{n.n-1}$.

3°. After the ſame manner the expectation upon the third choice will be $\frac{b.a.b-1}{n.n-1.n-2}$, which we will likewiſe ſuppoſe to be paid him out of the ſtake, ſtill ſuppoſing a black counter taken out of the heap.

4°. A may have out of the remainder the ſum $\frac{b.a.b-1.b-2}{n.n-1.n-2.n-3}$; and ſo of the reſt till the whole ſtake be exhauſted. Wherefore having written the following ſeries; viz. $\frac{a}{n}+\frac{b}{n-1}P+\frac{b-1}{n-2}Q+\frac{b-2}{n-3}R+\frac{b-3}{n-4}S$, &c. wherein P, Q, R, S, &c. denote the preceding terms, take as many terms of this ſeries as there are units in $b+1$, (for the number of drawings cannot exceed $b+1$) then take for A the firſt, fourth, ſeventh, &c. terms; take for B the ſecond, fifth, eighth, &c. for C the third, ſixth, &c. and the ſum of thoſe terms will be the reſpective expectations of A, B, C, or becauſe the ſtake is fixed, theſe ſums will be proportional to the reſpective probabilities of winning.

Now to apply this to the preſent caſe, make $n=12$, $a=4$, $b=8$, and the general ſeries will become $\frac{4}{12}+\frac{8}{11}P+\frac{7}{10}Q+\frac{6}{9}R+\frac{5}{8}S+\frac{4}{7}T+\frac{3}{6}U+\frac{2}{5}X+\frac{1}{4}Y$; or multiplying the whole by 495, to take away the fractions, the ſeries will be $165+120+84+56+35+20+10+4+1$.

Therefore, aſſigning to A $165+56+10=231$, to B $120+35+4=159$, to C $84+20+1=105$; the probabilities of winning will be proportional to the numbers 231, 159, 105, or 77, 53, 35.

A wagers with B, that in taking out ſeven counters, blindfold, from a heap containing 12 counters, four of them white, and eight black, three of them ſhall be white ones: What is the ratio of their expectancies?—1°. Seek how many different ſevens can be taken out of 12; they will be found by the method of combinations to be 792.

$$\frac{12}{1}\times\frac{11}{2}\times\frac{10}{3}\times\frac{9}{4}\times\frac{8}{5}\times\frac{7}{6}\times\frac{6}{7}=792.$$

2°. Set aſide three white ones, and find the different combinations of 4 in 8 black ones, they will be found to be 70.

$$\frac{8}{1}\times\frac{7}{2}\times\frac{6}{3}\times\frac{5}{4}=70.$$

And ſince there are four ways in which 3 white may be taken out of 4; multiply 70 by 4, and it gives 280 for the different ways whereby three whites may come out with four blacks.

3°. By the common laws of gaming, he is reputed a winner who does more than is required, unleſs the contrary be expreſsly agreed on; and therefore, if A takes out four white counters with three black ones, he wins. Set aſide four whites, and then find the combinations of three of the eight blacks with four whites, there will appear to be 56.

$$\frac{8}{1}\times\frac{7}{2}\times\frac{6}{3}=56.$$

4°. A therefore has $280+56=336$ chances whereby he may win, which taken from 792, the whole number of chances leaves 456 for thoſe whereby he may loſe. The ratio of the chances of A, therefore, to that of B, is as 336 to 456, or as 14 to 19.

If any number of gameſters, A, B, C, D, E, &c. equally ſkilful, depoſit each one piece of money, and engage on theſe conditions, that two of them, A and B, beginning the game, whichever of them ſhall be overcome, ſhall give place to the third C, who is to play with the conqueror; and the conqueror here to be taken up by the fourth man D; and thus on, till ſome one, having conquered them all round, draws the ſtake: What is the ratio of their expectancies?—This problem, M. Bernouilli ſolves analytically. Here, calling the number of gameſters $n+1$, he finds that the probabilities of any two immediately following each other in the courſe of playing, are in the ratio of $1+2^n$ to 2^n; and therefore the expectancies of the ſeveral gameſters A, B, C, D, E, &c. are in a geometrical progreſſion $1+2^n:2n::a:c::c:d::d:e$, &c.

Hence it is eaſy to determine the ſtate of the probabilities of any two gameſters, either before the game, or in the courſe thereof. If, e. gr. there be three gameſters, A, B, C; then $n=2$, and $1+n^2=5$, $n^2=4$: hence 5, 5 and 4, are as their reſpective chances for winning, before A has overcome B, or B, C; and therefore their expectancies as $\frac{5}{14}$, $\frac{5}{14}$, $\frac{4}{14}$: for all of them taken together muſt make 1, or abſolute certainty. After A has overcome B, the probabilities for A, B, and C, will be $\frac{1}{7}$, $\frac{2}{7}$, $\frac{4}{7}$, as in the anſwer above. If there be four gameſters, A, B, C, D, their probabilities from the beginning will be as 81, 81, 72, 64; for here $n=3$, and $1+2^n=9$, $2^n=8$, then $9:8:8:\frac{64}{9}$; conſequently 9, 9, 8, $\frac{64}{9}$, are the reſpective chances for A, B, C, and D, before they begin to play; multiply each number by 9 to avoid fractions, and we have 81, 81, 72, 64, the numbers above given. After A has beat B and C, the probabilities of C, B, D, A, will in whole numbers be as 16, 18, 28, 27.

Three gameſters, A, B, and C, whoſe dexterities are equal, depoſit each one piece, and engage upon theſe terms: that two of them ſhall begin to play, and that the vanquiſhed party ſhall give place to the third, who is to take up the conqueror, and the ſame condition to go round; each perſon, when vanquiſhed, forfeiting a certain ſum to the main ſtake, which ſhall be all ſwept by the perſon who firſt beats the other two ſucceſſively. How much

much, now, is the chance of A, better or worſe than that of C.

1°. If the forfeiture be to the ſum each perſon firſt depoſited, as 7 to 6, the gameſters are upon equal footing. 2°. If the forfeiture be in a leſs ratio to the depoſit, A and B are on a better footing than C; if in a greater ratio, the advantage is on the ſide of C. 3°. After A has overcome B once, the probabilities are as $\frac{12}{7}$, $\frac{6}{7}$, $\frac{3}{7}$; or as 4, 2, 1; viz. that of A the greateſt, and of B the leaſt.

M. Bernouilli gives an analytical ſolution of the ſame problem, only made more general; as not being confined to three gameſters, but extending to any number, at pleaſure.

A and B, two gameſters of equal dexterity, play with a given number of balls; after ſome time, A wants 1 of being up, and B, 3: What is the ratio of their chances? —A's expectancy is worth $\frac{7}{8}$ of the ſtake, and B's only $\frac{1}{8}$; ſo that their chances are as 7 to 1.

Two gameſters, A and B, of equal dexterity, are engaged in play, on this condition, that as often as A exceeds B, he ſhall give him one piece of money, and that B ſhall do the like, as oft as A exceeds him; and that they ſhall not leave off till one has won all the other's money: each now having four pieces, two by-ſtanders, R and S, lay a wager on the number of turns in which the game ſhall be finiſhed; viz. R lays that it ſhall be over in ten turns: What is the value of the expectancy of S? Anſwer $\frac{560}{1024}$, or $\frac{33}{64}$ of the wager; or it is to that of R, as 560 to 464.

If each player had five pieces, and the wager were, that the game ſhall end in ten turns, and the dexterity of A were double that of B, the expectancy of S would be $\frac{1800}{3561}$.

If each gameſter had four pieces, and the ratio of the dexterity were required to make it an even wager, that the game ends in four turns, it will be found that the one muſt be to the other as 5,274 to 1.

If each gameſter have four pieces, and the ratio of their dexterities be required to make it an even lay, that the game ſhall be ended in ſix turns, the anſwer will be found to be as 2,576 to 1.

GAMMUT, GAM, GAMMA, or GAMMAUT, in muſic, a ſcale whereon we learn to ſound the muſical notes, *ut*, *re*, *mi*, *fa*, *ſol*, *la*, in their ſeveral orders and diſpoſitions. See NOTE and SCALE.

The invention of this ſcale is owing to Guido Aretine; tho' it is not ſo properly an invention as an improvement on the diagram, or ſcale of the Grecians. See the article DIAGRAM.

The gammut is alſo called the harmonical hand, by reaſon that Guido made firſt uſe of the figure of the hand to demonſtrate the progreſſion of his ſounds.

Guido, finding the diagram of the ancients of too ſmall an extent, added five more chords or notes to it; one below the proſlambanomenos of the ancients, and four above the note hyperbolæon. The firſt he called hypoproſlambanomenos, and denoted it by the letter G, or the Greek Γ, gamma; which note being at the head of the ſcale, occaſioned the whole ſcale to be called by the name of gamm, or gammut. This ſcale is divided into three ſeries or columns, the firſt called durum, the ſecond natural, and the third molle, as repreſented by the ſcheme in plate LXVII. *fig.* 5.

The uſe of this ſcale is to make the paſſages and tranſitions from B molle to B durum, by means of tones and ſemitones. The ſeries of B natural ſtanding between the other two, communicates with both, ſo that to name the chord of the ſcale by theſe ſyllables, if we would have the ſemitones in their natural places, viz. *b*, *c*, and *e*, *f*; then we apply *ut* to *g*; and after *la* we go into the ſeries of B natural, at *fa*; and after the *la* of this, we return to the former at *mi*; and ſo on. And we may begin at *ut* in *c*, and paſs into the firſt ſeries at *mi*, and then back to the other at *fa*, by which means the one tranſition is a ſemitone, viz. *la*, *fa*, and the other a tone, *la*, *mi*. To follow the order of B molle, we may begin with *ut* in *c* or *f*, and make each ſemitone after the ſame manner.

Hence came the barbarous names of gammut, are, B *mi*, &c. But what perplexed work is here with ſo many different ſyllables applied to each chord, and all to mark the places of the ſemitones, which the ſimple letters *a*, *b*, *c*, &c. do as well, and with more eaſe.

Several alterations have been made in the gammut. M. le Murs particularly added a ſeventh ſyllable, viz. *ſi*; and the Engliſh uſually throw out that and *ut*, and make the other ſerve for all, as will be ſhewn under the article SOLFAING.

GAMMUT, or GAMM, is alſo the firſt or graveſt note in the modern ſcale of muſic, the reaſon of which is ſhewn under the preceding article.

GANDER, in ornithology, the male of the gooſe kind; one of which, it is ſaid, will ſerve five geeſe. See GOOSE.

GANGLIO, or GANGLION, in ſurgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part, uſually without any pain to the patient. Tho' ganglions ſo nearly reſemble an encyſted tumour, that Celſus makes them one and the ſame; yet their difference may appear, if it were only from their different ſeats; ganglions being confined to the tendons and ligaments of the hands and feet, whereas encyſted tumours are not reſtrained to any part of the body. See the article ENCYSTED.

With regard to the cauſe of ganglions, they ſeem generally to proceed from an inſpiſſation of the viſcid juices, which are let out, and lodged betwixt the fibres and membranes, when the tendons and ligaments of thoſe parts have been injured by a fall, blow, ſtrain, contuſion, or the like, in which caſe they gradually increaſe more or leſs, as long as the fibres yield; the juices find vent ſo as to advance to the ſize of a filbert, walnut, or even a pigeon's egg: ſome are oblong, round, or oval, with an equal or uneven ſurface: ſome of them which are recent, may be eaſily diſperſed; and others, which have been of long ſtanding, hardly yield to any remedies but the knife.

The inſpiſſated matter of a recent ganglion may often be happily diſperſed by barely rubbing the tumour well every morning with the faſting ſaliva, and binding a plate of lead on it afterwards for ſeveral weeks ſucceſſively. Many attribute a greater diſcutient virtue to the lead, when it has firſt had ſome mercury rubbed on it. Foreſtus, and others, adviſe the uſe of a plaſter of ammoniac and mercury, and often to rub them with oil of ſoap. Others write, that a cure may be readily performed, if the patient lays his hand upon a table, and ſtrikes on the tumour with his fiſt: but care ſhould be taken not to injure the bones, tendons, or other parts of the hand in ſtriking the tumour; and the ſame care muſt be taken if there is a neceſſity of having recourſe to cauſtics or inciſion, in order to remove them.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a ſtate of putrefaction. A gangrene is diſtinguiſhed from a ſphacelus, inaſmuch as this latter is not an incipient but an abſolute and perfect corruption, or death of the parts, already made. See the article SPHACELUS.

A gangrene may be diſcovered generally from the following ſigns; namely, the inflammation, with its ſymptoms, which have all along been very violent, do generally undergo a ſudden change, as if they were going off. The parts which were before ſwelled and tenſe, do now grow ſoft and flaccid, and upon preſſing with the finger on the ſkin and fat, its impreſſion remains behind, as in an œdema; at length the cuticula ſeparates from the cutis, often riſing up in bliſters, like thoſe on burns, filled with a reddiſh, yellowiſh, and black humour; and the ſenſe of the limb is in ſome degree diminiſhed. See the article OEDEMA.

The cauſes of a gangrene, as well as a ſphacelus, are either external or internal. Among the internal cauſes are reckoned an eryſipelas, and all other inflammations which riſe ſpontaneouſly, and can by no means be diſperſed, nor brought to ſuppuration. Inflammations of this kind uſually proceed from the blood's being too acrimonious, or corrupted by the bile, or in a ſcorbutus; or when the circulation of blood is too quick, or too ſlow, by reaſon of old age, or any other weakneſs; or, laſtly, when the patient uſes a perverſe courſe of life with reſpect

ſpect to diet, and paſſions of the mind, eſpecially anger, grief, and fear, during the time of the inflammation. By external cauſes are intended injuries of the air, cold water, and the application of topical remedies externally to the inflamed parts; which are either cooling, aſtringent, fat, oily, or the like; together with all great external hurts or accidents, which frequently happen to the body through falls, blows, &c. as in wounds, fractures, luxations, &c.

A gangrene is for the generality never without danger, becauſe it eaſily changes into a ſphacelus, or intire mortification, which never admits of cure but by taking off the dead parts. But a gangrene which is ſlight, incipient, and not ſpread far, but only affects the ſkin and fat, is not very difficult to cure; eſpecially when it happens in a young and ſtout patient, in a mild and temperate ſeaſon, and does little or no injury to the muſcles and nerves: but the larger, more violent, and confirmed is the gangrene, and the faſter it ſpreads, the more difficult it is generally to effect a cure, eſpecially in an old or weak patient; or in an ill habit of body, from a dropſy, phthiſis, or ſcorbutus: the weather alſo being too hot, or very cold, or the parts affected being near the thorax, or abdomen, may make the caſe more dangerous. Nor can this caſe be neglected without the utmoſt danger of life, or its ſuddenly turning into a ſphacelus.

Therefore the gangrene muſt be treated ſo, that it may not terminate in a ſphacelus. For which end, firſt of all, in plethoric and ſtrong habits, the patient muſt be bled largely, and the operation repeated at diſcretion; but in weak habits, it ſhould be omitted. The remainder of the treatment, according to Heiſter, will conſiſt chiefly in obſerving the following directions. 1. To be careful in the beginning to prevent all violent external cauſes of inflammations, too ſtrict a bandage in wounds and fractures, all foreign bodies which are ſtuck in the part, as thorns, ſplinters, &c. improper medicines externally applied, as ointments, oils, and plaſters, with cooling and aſtringent things; all which ſhould be removed as ſoon as poſſible. 2. The next obſervation reſpects chiefly the keeping up the patient's ſtrength, eſpecially in weak and old people. This may be beſt effected by ordering a diet which not only affords good juices, but is alſo well accommodated to the age, conſtitution, and other circumſtances of the patient. In weak and old people, the moſt ſuitable diet will be ſoops, ſtrengthening broths, &c. With reſpect to medicines, the moſt proper are the corroborants, uſually termed cordials, as the ſpirits, eſſences, powders, and electuaries of that tribe; eſpecially made up or mixed with confected alkermes. It will be proper alſo, in this caſe, frequently to apply a ſponge to the noſe or carpal arteries, which has been dipped in hungary water; alſo to bind it to the temples. For patients who are of a more warm, ſanguine, and bilious habit, ſoops and ptiſans mixed with acid juice of citrons or lemons, will be very proper ſtrengtheners; at the ſame time, not neglecting other medicines, which are proper to be uſed in fevers; but the Peruvian bark is by many celebrated in this diſorder beyond any other internal medicine. 3. The chief and laſt obſervation concerning the treatment of a gangrene, is chiefly to diſcharge the ſtagnating and corrupted blood from the parts affected as ſoon as poſſible, to prevent the neighbouring parts from being affected thereby.

The principal means to effect this are, 1. To make uſe of proper internal, ſtrengthening medicines. 2. To make ſcarifications on the part affected, by numerous inciſions lengthways, and of a ſufficient depth, in order to diſcharge the ſtagnating and corrupted blood, and to make way for the ingreſs of the virtues of the diſcutient medicines which are applied externally. Laſtly, 3. Diſcutient, ſtimulating, and balſamic fomentations and cataplaſms which reſiſt putrefaction, are to be carefully applied to the diſordered part.

The fomentation is to be applied hot, ſeveral times in a day, to the parts affected, by means of linnen or woollen cloths; and to give a laſting warmth, we may apply a hot tile wrapped up in a thick cloth, or a hot bag of ſand.

GANNET, in ornithology, a bird of the larus or gull-kind, frequent on the weſtern coaſts of England. It is equal in ſize to the common duck. The upper part of the body is of a deep ruſty ferrugineous colour, much like that of the common buzzard; and the breaſt and belly are alſo brown, but paler. It is an extremely ſingular ſpecies, its whole aſpect, in ſome degree, approaching to that of ſome of the larger birds of prey.

GANTLET, or GAUNTLET, a large kind of glove, made of iron, and the fingers covered with ſmall plates. It was formerly worn by cavaliers, when armed at all points.

GAOL, a priſon, or place of legal confinement.

GAOL-DELIVERY, is where a commiſſion or patent is granted by the king in the nature of a letter, to certain perſons, who are thereby appointed his juſtices, or to two or three of them, authorizing them to deliver his gaol, at ſuch a place, of the priſoners contained therein; and for that end it commands them to meet at ſuch place, at the time they themſelves ſhall appoint, when the ſheriff of the county is commanded to bring all the priſoners in the gaol before them, &c. 4 *Inſt.* 168.

GARBLER *of Spices*, an ancient officer in the city of London, who is authorized to go into ſhops, ware-houſes, &c. there to view and ſearch drugs, ſpices, &c. and ſee that they be garbled or cleanſed from the droſs and duſt wherewith they are mixed.

GARDANT, or GUARDANT, in heraldry, denotes any beaſt full faced, and looking right forward.

GARDEN, a plot of ground, cultivated and properly ornamented with a variety of plants, flowers, fruit, &c.

Gardens are uſually diſtinguiſhed into flower-garden, fruit-garden, and kitchen-garden; the firſt of which, being deſigned for pleaſure and ornament, is to be placed in the moſt conſpicuous part, that is, next to the back front of the houſe; and the two latter being deſigned for uſe, ſhould be placed leſs in ſight. But though the fruit and kitchen-gardens are here mentioned as two diſtinct gardens, yet they are now uſually in one; and that with good reaſon, ſince they both require to be placed out of the view of the houſe. See KITCHEN-GARDEN.

In the choice of a place proper for a garden, the moſt eſſential points to be conſidered are the ſituation, the ſoil, the expoſure, water, and proſpect.

1. As to the ſituation, it ought to be ſuch a one as is wholeſome, and in a place neither too high nor too low; for if a garden be too high, it will be expoſed to the winds, which are very prejudicial to trees; and if it be too low, the dampneſs, the vermin, and the venomous creatures that breed in ponds and marſhy places, add much to their inſalubrity. The moſt happy ſituation is on the ſide of a hill, eſpecially if the ſlope be eaſy, and in a manner imperceptible; if a good deal of level ground be near the houſe; and if it abounds with ſprings of water; for, being ſheltered from the fury of the winds, and the violent heat of the ſun, a temperate air will be there enjoyed; and the water that deſcends from the top of the hill, either from ſprings or rain, will not only ſupply fountains, canals, and caſcades for ornament, but when it has performed its office, will water the adjacent valleys, and, if it be not ſuffered to ſtagnate, will render them fertile and wholeſome. Indeed if the declivity of the hill be too ſteep, and the water be too abundant, a garden on the ſide of it may frequently ſuffer, by having trees torn up by torrents and floods; and by the tumbling down of the earth above, the walls may be demoliſhed, and the walks ſpoiled. It cannot, however, be denied, that the ſituation on a plain, or flat, has ſeveral advantages which the higher ſituation has not: for floods and rain commit no damage; there is a continued proſpect of champaigns, interſected by rivers, ponds, and brooks, meadows and hills covered with woods or buildings; beſides, the level ſurface is leſs tireſome to walk on, and leſs chargeable, than that on the ſide of a hill, ſince terrace walks and ſteps are not there neceſſary: but the greateſt diſadvantage of flat gardens, is the want of thoſe extenſive proſpects which riſing grounds afford.

2. A good earth, or ſoil, is next to be conſidered; for it is ſcarce poſſible to make a fine garden in a bad ſoil: there are indeed ways to meliorate ground, but they are very expenſive; and ſometimes when the expence has been beſtowed of laying good earth three feet deep over the whole ſurface, a whole garden has been ruined

when the roots of the trees have come to reach the natural bottom.

To judge of the quality of the ſoil, obſerve whether there be any heath, thiſtles, or ſuch like weeds growing ſpontaneouſly in it; for they are certain ſigns that the ground is poor. Or if there be large trees growing thereabouts, obſerve whether they grow crooked, ill ſhaped, and grubby; and whether they are of a faded green, and full of moſs, or infeſted with vermin; if this be the caſe, the place is to be rejected: but, on the contrary, if it be covered with good graſs fit for paſture, you may then be encouraged to try the depth of the ſoil. To know this, dig holes in ſeveral places, ſix feet wide, and four feet deep; and if you find three feet of good earth, it will do very well; but leſs than two, will not be ſufficient. The quality of good ground is neither to be ſtony, nor too hard to work; neither too dry, too moiſt, nor too ſandy and light; nor too ſtrong and clayey, which is the worſt of all for gardens.

3. The next requiſite is water, the want of which is one of the greateſt inconveniencies that can attend a garden, and will bring a certain mortality upon whatever is planted in it, eſpecially in the greater droughts that often happen in a hot and dry ſituation in ſummer; beſides, its uſefulneſs in fine gardens for making fountains, canals, caſcades, &c. which are the greateſt ornaments of a garden.

4. The laſt thing to be conſidered, is the proſpect of a fine country; and though this is not ſo abſolutely neceſſary as water, yet it is one of the moſt agreeable beauties of a fine garden: beſides, if a garden be planted in a low place that has no kind of proſpect, it will not only be diſagreeable, but unwholeſome.

In the laying out and planting of gardens, the beauties of nature ſhould always be ſtudied; for the nearer a garden approaches to nature, the longer it will pleaſe. The area of a handſome garden may take up thirty or forty acres, but not more; and the following rules ſhould be obſerved in the diſpoſition of it. There ought always to be a deſcent at leaſt three ſteps from the houſe to the garden; this will render the houſe more dry and wholeſome, and the proſpect on entering the garden more extenſive. The firſt thing that ſhould preſent itſelf to view, ſhould be an open lawn of graſs, which ought to be conſiderably broader than the front of the building; and if the depth be one half more than the width, it will have a better effect: if on the ſides of the lawn there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn ſhould be ſurrounded with a gravel walk, on the outſide of which ſhould be borders three or four feet wide, for flowers: and from the back of theſe, the proſpect will be agreeably terminated by a ſlope of ever-green ſhrubs, which, however, ſhould never be ſuffered to exclude agreeable proſpects, or the view of handſome buildings. Theſe walks may lead thro' the different plantations, gently winding about in an eaſy natural manner, which will be more agreeable than either thoſe long ſtraight walks, too frequently ſeen in gardens, or thoſe ſerpentine windings, that are twiſted about into ſo many ſhort turns, as to render it difficult to walk in them: and as no garden can be pleaſing where there is a want of ſhade and ſhelter, theſe walks ſhould lead as ſoon as poſſible into plantations, where perſons may walk in private, and be ſheltered from the wind. Where the borders of the gardens are fenced with walls or pales, they ſhould be concealed with plantations of flowering-ſhrubs intermixed with laurels, and other ever-greens, which will have a good effect, and at the ſame time conceal the fences, which are diſagreeable, when left naked and expoſed to the ſight. Groves are the moſt agreeable parts of a garden, ſo that there cannot be too many of them; only that they muſt not be too near the houſe, nor be ſuffered to block up agreeable proſpects. To accompany parterres, groves opened in compartments, quincunxes, and arbour-work with fountains, &c. are very agreeable. Some groves of ever-greens ſhould be planted in proper places, and ſome ſquares of trees of this kind may alſo be planted among the other wood. See QUINCUNX, &c.

Narrow rivulets, if they have a conſtant ſtream, and are judiciouſly led about a garden, have a better effect than many of the large ſtagnating ponds or canals ſo frequently made in large gardens. When wilderneſſes are intended, they ſhould not be cut into ſtars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great deſign appear trifling. Buildings, ſtatues, and vaſes, appear very beautiful; but they ſhould never be placed too near each other: magnificent fountains are alſo very ornamental; but they ought never to be introduced, except there be water to keep them conſtantly running. The ſame may alſo be obſerved of caſcades and other falls of water. See the articles CASCADES, FOUNTAINS, &c.

In ſhort, the ſeveral parts of a garden ſhould be diverſified; but in places where the eye takes in the whole at once, the two ſides ſhould be always the ſame. In the buſineſs of deſigns, the aim ſhould be always at what is natural, great, and noble. The general diſpoſition of a garden, and of its parts, ought to be accommodated to the different ſituations of the ground, to humour its inequalities, to proportion the number and ſorts of trees and ſhrubs to each part, and to ſhut out from the view of the garden no objects that may become ornamental. And before a garden is planned out, it ought ever to be conſidered, what it will be when the trees have had twenty years growth. *Miller's Gard. Dict.*

GARDENING, a branch of agriculture, containing the cultivation of gardens. See the preceding article.

The art of gardening affords a variety of delights. It teaches how to diſpoſe fruit trees, flowers, and herbs to the beſt advantage, whether for profit or pleaſure; and ſhews how to prepare the ſoil for ſowing the different kinds of ſeeds, as well as how to treat the plants when grown up. It is a pleaſure to behold a perſon employed, amongſt the plants of a ſpacious garden, in reforming, by proper methods, a growth of natural wildings; to ſee him cultivate mutual alliances between his plants, by grafting or inoculation, whereby the bad are meliorated, and the good rendered ſtill more perfect. By this means, a plant taken from the wilds of a foreſt, ſoftens its ſavage nature, and will ſometimes diveſt itſelf of its thorns, when it happens to be aſſociated with a domeſtic one. As to the ſeveral parts and operation of gardening, the reader will find them deſcribed under the articles of SOWING, PLANTING, TRANSPLANTING, GRAFTING, INOCULATION, PRUNING, NURSERY, HOT-BED, GREEN-HOUSE, WALK, TERRACE, ALLEY, AVENUE, ARBOUR, GROVE, ESPALIERS, STANDARDS, &c.

GARGARISM, in medicine, is ſometimes taken, in a large ſenſe, for every collution of the mouth; but, ſtrictly ſpeaking, it ſignifies a liquid medicine, appropriated to affections of the mouth, gums, fauces, larynx, and ſometimes of the head, received into the mouth, and there uſed by way of collution, without deglutition.

GARLAND, among ſailors, a ſort of net uſed by the different meſſes of a ſhip of war to hang their proviſions in, in the apartment where they eat and ſleep.

GARNET, among ſailors, a ſort of tackle or complication of pullies, fixed to the main-ſtay of a merchant-ſhip to hoiſt the cargo in and out at the time of lading and delivering her.

Alſo a rope fixed to the lower corners or clues of the main-ſail and fore-ſail to draw them up to the yard occaſionally, and hence called clue-garnet. See the article CLUE-GARNET.

GARNET, *Granatus*, in natural hiſtory, a very beautiful gem, of a red colour, with an admixture of bluiſh.

When pure and free from blemiſhes, it is little inferior, in appearance, to the oriental ruby, tho' only of a middle degree of hardneſs between the ſapphire and common cryſtal. It is found of various ſizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names, according to their different degrees of colour. 1. The garnet, ſimply ſo called, is the fineſt and moſt valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very ſtrong but not deep red, and has a fairer caſt of the blue: this is a very beautiful gem. 3. The

ſorane of ſerain garnet, that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the rock-ruby.

Garnets are very properly diſtinguiſhed into the oriental and occidental kinds, as being found in Europe as well as the Eaſt-Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European ones are common in Italy, Hungary, and Bohemia.

Some authors have ſuppoſed the deeper-coloured garnet to be the ſame with the carbuncle of the antients, from which it really differs; ſince, on receiving the ſun's beams, it never gives ſo true a fire-colour as the carbuncle. See CARBUNCLE.

GARRISON, in the art of war, a body of forces, diſpoſed in a fortreſs, to defend it againſt the enemy, or to keep the inhabitants in ſubjection; or even to be ſubſiſted during the winter ſeaſon; hence, garriſon and winter-quarters are ſometimes uſed indifferently, for the ſame thing; and ſometimes they denote different things. In the latter caſe, a garriſon is a place wherein forces are maintained to ſecure it; and where they keep regular guard, as a frontier town, a citadel, caſtle, tower, &c. The garriſon ſhould always be ſtronger than the townſmen.

Winter-quarters ſignify a place where a number of forces are laid up in the winter ſeaſon, without keeping the regular guard. See WINTER-QUARTERS.

GARRISON-TOWN, a ſtrong place in which troops are quartered, and do duty, for the ſecurity thereof, keeping ſtrong guards at each port, and a main guard in the market-place.

Order of the GARTER, a military order of knighthood, the moſt noble and antient of any lay-order in the world, inſtituted by king Edward III. This order conſiſts of twenty ſix knights-companions, generally princes and peers, whereof the king of England is the ſovereign or chief. They are a college or corporation, having a great and little ſeal.

Their officers are a prelate, chancellor, regiſter, king at arms, and uſher of the black rod. They have alſo a dean with twelve canons, and petty canons, vergers, and twenty-ſix penſioners, or poor knights. The prelate is the head. This office is veſted in the biſhop of Wincheſter, and has ever been ſo. Next to the prelate is the chancellor, which office is veſted in the biſhop of Saliſbury, who keeps the ſeals, &c. The next is the regiſter, who by his oath is to enter upon the regiſtry the ſcrutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two diſtinct offices united in one perſon. Garter carries the rod and ſcepter at the feaſt of St. George, the protector of this order, when the ſovereign is preſent. He notifies the elections of new knights, attends the ſolemnity of their inſtallations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See KING *at Arms*.

All theſe officers, except the prelate, have fees and penſions. The college of the order is ſeated in the caſtle of Windſor, with the chapel of St. George, and the chapter-houſe, erected by the founder for that purpoſe. The habit and enſign of the order are a garter, mantle, cap, george, and collar. The four firſt were aſſigned the knights companions by the founder; and the george and collar by Henry VIII. The garter (ſee plate LXVII. *fig.* 6.) challenges preheminence over all the other parts of the dreſs, by reaſon that from it the noble order is denominated; that it is the firſt part of the habit preſented to foreign princes, and abſent knights, who, and all other knights elect, are therewith firſt adorned; and it is of ſo great honour and grandeur, that by the bare inveſtiture with this noble enſign, the knights are eſteemed companions of the greateſt military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QVI MAL Y PENSE; i. e. "Shame to him that thinks evil hereof." The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted ſhame and defiance upon him that ſhould dare to think amiſs of the juſt enterprize he had undertaken, for recovering his lawful right to that crown; and that the bravery of thoſe knights whom he had elected into this order, was ſuch as would enable him to maintain the quarrel againſt thoſe that thought ill of it.

The mantle (*fig.* 7.) is the chief of thoſe veſtments made uſe of upon all ſolemn occaſions. The colour of the mantle is by the ſtatutes appointed to be blue. The length of the train of the mantle only diſtinguiſhes the ſovereign from the knights companions. To the collar of the mantle is fixed a pair of long ſtrings, anciently wove with blue ſilk only, but now twiſted round, and made of Venice gold and ſilk, of the colour of the robe, with knobs, or buttons, and taſſels at the end. The left ſhoulder of the mantle has from the inſtitution been adorned with a large garter, with the device HONI SOIT, &c. Within this is the croſs of the order, which was ordained to be worn at all times by king Charles I. At length the ſtar was introduced, being a ſort of croſs irradiated with beams of ſilver. *Fig.* 8.

The collar (*fig.* 9.) is appointed to be compoſed of pieces of gold in faſhion of garters, the ground enamelled blue, and the motto gold. See COLLAR.

The manner of electing a knight companion into this moſt noble order, and the ceremonies of inveſtiture, are as follow. When the ſovereign deſigns to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which paſſing both under the ſovereign's ſign manual and ſignet of the order, are ſent to the perſon by garter principal king at arms, and are in this manner, or to the ſame effect. "We, with the companions of our moſt noble order of the garter, aſſembled in chapter, holden this preſent day at our caſtle at Windſor, conſidering the virtuous fidelity you have ſhewn, and the honourable exploits you have done in our ſervice, by vindicating and maintaining our right, &c. have elected and choſen you one of the companions of our order. Therefore, we require you to make your ſpeedy repair unto us, to receive the enſigns thereof, and be ready for your inſtallation upon the—day of this preſent month, &c."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the ſame, is, at the time of election, buckled upon the left leg, by two of the ſenior companions, who receive it from the ſovereign, to whom it was preſented upon a velvet cuſhion by garter king at arms, with the uſual reverence, whilſt the chancellor reads the following admonition, enjoined by the ſtatutes. "To the honour of God omnipotent, and in memorial of the bleſſed martyr St. George, tye about thy leg, for thy renown, this noble garter; wear it as the ſymbol of the moſt illuſtrious order, never to be forgotten, or laid aſide; that thereby thou mayeſt be admoniſhed to be courageous, and having undertaken a juſt war in which thou ſhalt be engaged, thou mayeſt ſtand firm, valiantly fight, and ſucceſſively conquer."

The princely garter being thus buckled on, and the words of its ſignification pronounced, the knight elect is brought before the ſovereign, who puts about his neck, kneeling, a ſky coloured ribbon, (*fig.* 10.) whereunto is appendant, wrought in gold within the garter, the image of St. George on horſeback, with his ſword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the bleſſed martyr and ſoldier of Chriſt, St. George, by whoſe imitation provoked, thou mayeſt ſo overpaſs both proſperous and adverſe adventures, that having ſtoutly vanquiſhed thy enemies both of body and ſoul, thou mayeſt not only receive the praiſe of this tranſient combat, but be crowned with the palm of eternal victory."

Then the knight elected kiſſes the ſovereign's hand, thanks his majeſty for the great honour done him, riſes up, and ſalutes all the companions ſeverally, who return their congratulations. *Fig.* 7. exhibits a view of a knight of the garter in the habit of this order.

Since the inſtitution of this order, there have been eight

eight emperors, and twenty-eight kings, beſides numerous ſovereign princes enrolled as companions thereof. Its origin is ſomewhat differently related: the common account is, that it was erected in honour of a garter of the counteſs of Saliſbury, which ſhe dropped dancing with king Edward, and which that prince picked up; but our beſt antiquaries think it was inſtituted on account of the victory over the French at Creſſy, where the king ordered his garter to be diſplayed as a ſignal of the battle.

GAS, among chemiſts, a term made uſe of by Helmont, to ſignify, in general, ſpirit incapable of coagulation, ſuch as proceeds from fermented wine.

GASKET, among ſailors, a ſort of platted cord faſtened to the ſail-yards of a ſhip to furl, or tie up the ſail to the yard: it is uſed by wrapping it round the yard and ſail, the latter of which is rolled up cloſe to the former for that purpoſe.

GASTRO-EPIPLOIC Vein, a vein that opens into the vena portæ. See Vein.

GASTRIC, in general, ſomething belonging to the ſtomach. See Stomach.

Gastric Juice, *gaſtricus ſuccus*, among phyſicians, a thin, pellucid, ſpumous, and ſaltiſh liquor, which continually diſtills from the glands of the ſtomach for the dilution of the food. See Food.

Gastric Veſſels, in anatomy, the arteries and veins of the ſtomach. See the articles Artery and Vein.

GASTROCNEMIUS, in anatomy, the name of two thick, pretty broad, and oblong muſcles, which form a great part of what is called the calf of the leg. They are ſituated laterally with reſpect to each other under the poples.

Gastrocnemius is alſo the name of one of the extenſor-muſcles of the foot.

GASTRORAPHY, γαστροραφια, in ſurgery, the operation of ſowing up wounds of the abdomen.

GASTROTOMY, γαστροτομια, in ſurgery, the cutting open the abdomen and uterus, as in the Cæſarian ſection. See the article Cæsarian.

GATE, in architecture, a large door, leading, or giving entrance into a city, town, caſtle, palace, or other conſiderable building: or a place giving paſſage to perſons, horſes, coaches, or waggons, &c. As to their proportion, the principal gates for entrance through which coaches and waggons are to paſs, ought never to be leſs than ſeven feet in breadth, nor more than twelve, which laſt dimenſion is fit only for large buildings. The height of a gate is to be 1 ½ of the breadth, and ſomewhat more; but as for common gates in inns, under which waggons go loaded with hay, ſtraw, &c. the height of them may be twice their breadth.

Paled Gates, ſuch as are ſet up in fences for ſhutting up the paſſages into fields, and other incloſures.

Theſe are of two ſorts, either of ſawed or cleft timber.

GATE, in the manege, the going or pace of a horſe.

GAVELET, in law, an antient and ſpecial ceſſavit uſed in Kent, where the cuſtom of gavel-kind continues, by which the tenant, if he withdraws his rent and ſervices due to the lord, forfeits his lands and tenements.

Gavelet, in London, is a writ uſed in the huſtings, given to lords of rents in the city of London.

GAVELKIND, a tenure or cuſtom belonging to lands in the county of Kent, by which the lands of the father are, at his death, equally divided among all his ſons; or the land of a deceaſed brother, in caſe he leaves no iſſue, among all the brethren. This is by ſome called ancient ſocage-tenure; the cuſtom came from our Saxon anceſtors, among whom the inheritance of lands did not deſcend to the eldeſt, but to all the ſons alike; and the reaſon why it was retained in Kent is, becauſe the Kentiſh men were not conquered by the Normans in the time of William I.

The particular cuſtoms attending this tenure are, that the heir, at the age of fifteen, may give or ſell his lands in gavelkind; and though the father is attainted of treaſon and felony, and ſuffers death, the ſon ſhall inherit. A wife ſhall be endowed of a moiety of the gavelkind-lands, of which her huſband died ſeiſed, during her widow-hood. Likewiſe a huſband may be tenant by curteſy of half his wife's lands, without having any iſſue by her; but if he marries again, not having iſſue, he forfeits his tenancy.

GAVELMAN, a tenant liable to pay tribute.

GAVELMED, the duty of mowing graſs, required by the lord of his cuſtomary tenants.

GAUGE, or Gage. See Gage.

Gauge Line, on the gauging-rod. See the article Gauging.

Gauge-Point, of a ſolid meaſure, the diameter of a circle, whoſe area is equal to the ſolid content of the ſame meaſure. Thus, the ſolidity of a wine-gallon being 231 cubic inches, if you conceive a circle to contain ſo many inches, the diameter of it will be 17.15; and that will be the gauge-point of wine-meaſure. And an ale gallon, containing 282 cubic inches, by the ſame rule, the gauge-point for ale-meaſure will be found to be 19.15. After the ſame manner, may the gauge-point of any foreign meaſure be obtained; and from hence may be drawn this conſequence, that when the diameter of a cylinder, in inches, is equal to the gauge-point of any meaſure, given likewiſe in inches, every inch in length thereof will contain an integer of the ſame meaſure, *e. gr.* in a cylinder whoſe diameter is 17.15 inches, every inch in height contains one entire gallon in wine meaſure; and in another, whoſe diameter is 18.95 inches, every inch in length contains one ale-gallon.

GAUGER, a king's officer who is appointed to examine all tuns, pipes, hogſheads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are ſold in any place within the extent of his office.

GAUGING, the art of meaſuring the contents of all kinds of veſſels, thereby to determine the quantity of liquids, &c. they contain.

Gauging is a branch of ſtereometry. The principal veſſels that come under its operation are pipes, barrels, rundlets, and other caſks; alſo coolers, fats, backs, ſtills, &c.

The ſolid content of cubical, parallelopipedal, and priſmatical veſſels is found in cubic inches, &c. by multiplying the area of the baſe by the perpendicular altitude. And the area of cylindrical veſſels is found by multiplying the area of the circular baſe by the perpendicular altitude.

Before the content of a caſk can be known, its form or ſhape muſt be conſidered; for though the diameters and length of one caſk may be equal to thoſe of another, yet one of them may contain ſeveral gallons more than the other; and therefore the content of all caſks cannot be found by the ſame rule. Moſt writers, therefore, in treating of this ſubject, have taken it for granted, that every common caſk is in one of the following ſolids, viz.

1. The middle fruſtum of a ſpheroid (plate LXVIII. *fig.* 1.

2. The middle fruſtum of a parabolical ſpindle (*fig.* 2.

3. The middle fruſtum of two parabolical conoids abutting upon one common baſe (*fig.* 3.

4. The middle fruſtum of two cones abutting upon one common baſe (*fig.* 4.

Accordingly they have laid down rules for finding the contents of theſe ſolids, and by thoſe rules they ſuppoſe the content of any caſk may be found.

See the method of finding the area of theſe figures under their proper articles.

From what has been ſaid, it follows that, if we are not exact in aſſigning the caſk its true form, it is impoſſible we ſhould ever be exact in aſcertaining its contents. Now it is evident to thoſe converſant in theſe affairs, that there never was any caſk in the ſhape of any one of thoſe ſolids whoſe names they bear, unleſs it can be ſuppoſed that it was effected by chance, the cooper never intending them for ſuch: and though it ſhould be admitted that a caſk may approach nearly to the form of ſuch a ſolid, yet what officer had any rule to direct in aſcertaining its true form, or to which of the varieties it belonged? Whence it follows, that the beſt method of gauging all kinds of caſks is to reduce them to cylinders; that is, to find a mean diameter between the head and the bung, whence its content will always be found exceedingly near the truth. The following example will explain this method.

Suppoſe

Suppoſe the area caſk ABCD, (*fig.*5.) whoſe length AB = 32, 5 inches, the bung diameter CD = 31, and that of the head IK = 24, was required.—Lay your gauging-rod upon the bung C, ſo that it may be parallel to AB; then will HL = AB, the length, and, if twice HI be taken from CD, the remainder will be = IK, the head diameter. Make EC = HE, and meaſure EF, whoſe double being taken from CD, there will remain FG, the mean diameter, which ſuppoſe = 28.85. Then this caſk will be gauged by the following

Rule.—To the ſquare of the bung diameter, add the ſquare of the head, and four times the ſquare of the mean diameter; multiply this ſum by the length of the caſk, and divide by 2154,3 for ale, and by 1764,71 for wine, which will give the content reſpectively.

GAUGING-*Rule* is an inſtrument commonly made of box, and ſometimes ivory, exactly a foot long, one inch and two tenths broad, and $\frac{1}{4}$ of an inch thick.

Deſcription of the GAUGING *Rule.*—This inſtrument conſiſts of four parts, viz. a rule and three ſmall ſcales or ſliding-piece fitted nicely with grooves to ſlide in it.

The firſt marked BN, to ſlide by the line A, the ſecond marked CD, to ſlide between the lines D and E, (*fig.* 7.) and the third marked N, (*fig.* 8.) ſlides in the edge of the rule between the two lines marked ſeg. L *y*, ſeg. S *t*. When the ſliders B and C are drawn out to their due extent, the whole rule will be three feet in length.

Of the firſt face of the rule *fig.* 6. — On the firſt face of the ſliding-rule here deſcribed, are placed four lines of numbers; the firſt line of numbers conſiſts of two radius's, and is numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 10; and then again, 2, 3, 4, 5, 6, 7, 8, 9, 10. (*fig.* 6.) On this line are placed ſeveral braſs center pins. The firſt in the firſt radius at 2150,42, and the third likewiſe at the ſame number taken in the ſecond radius, having MB ſet to them, ſignifying that the aforeſaid number repreſents the cubic inches in a malt buſhel; the ſecond and fourth center pins are ſet at the number 282, on each radius; they have the letter A ſet to them, ſignifying that the aforeſaid number repreſents the cubic inches in an ale gallon, and the W on the line B, ſtands at 231, being the cubic inches in a wine gallon, you may ſee it is placed both in the firſt and ſecond radius, the C in the ſame line being placed at 3.14, which is the circumference of a circle whoſe diameter is unity.

The fourth line on the firſt face is a broken line of numbers of two radius's, numbered 2, 1, 9, 8, 7, 6, 5, 4, 3, 2, 1, 9, 8, 7, 6, 5, 4, 3. The number 1 is ſet againſt M. B. of the firſt radius of the line A; this line hath M. D. ſet to it, ſignifying malt-depth. Note, the little long black dots over the center pins are put directly over the proper numbers. This line of numbers hath A placed at the end thereof, and is called A for diſtinction's ſake.

2. The ſecond and third line of numbers which are on the ſliding piece BN, (and which may be called but one line) are exactly the ſame with the firſt line of numbers; the little black dot that is near the diviſion 7, on the firſt radius, having S *i* ſet after it, is put directly over .707, which is the ſide of a ſquare inſcribed in a circle whoſe diameter is unity. The black dot near unto the figure 9, after which is written S *e*, is ſet directly over .886, which is the ſide of a ſquare equal to the area of a circle whoſe diameter is unity.

Of the ſecond face of the rule, *fig.* 7. — 3. The ſecond face of the rule has one ſingle line of numbers marked D, and numbered 1, 2, 3, &c. to 10. The line C (on the ſlider) is a double line of numbers of the ſame length with the ſingle one D, and by this on the ſlider is the ſingle line of numbers of D again repeated, which anſwers to the ſquare and cube roots of the lines C and E; the WG on the line D being placed at 17,14 is the gauge point for wine, and AG placed at 18,9 is the gauge point for ale gallons; the MS which ſtand at 46,37 is the gauge point for a malt buſhel in ſquare meaſure: and MR being placed at 52,32 is the gauge point for a malt buſhel in round or circular meaſure; the TP which ſtands at 6,32 is the gauge-point for a pound of tallow neat; the line marked E on the ſecond face of the rule, is a triple line of numbers, and is numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, which 1 ſtands for 10, the next line being numbered 1, 2, 3, &c. to 10, which 10 ſtands for 100, the third line being numbered 1, 2, 3, &c. to 1000, having E after it, and therefore is called the line E for diſtinction's ſake. Its uſe is to find the cube root of any number, and to calculate diagonal lines for any meaſure or caſk whatſoever.

4. The two lines of numbers which are on the ſliding-piece marked C, are exactly the ſame as on the ſliding-piece on the other ſide the rule.

Of the third face (or edge) of the rule.—On one edge of the rule (*fig.* 8.) are placed two lines of ſegments of a ſpheroidal caſk, each numbered 1, 2, 4, &c. to 100; the firſt is for finding the ullage of a caſk taken as the middle fruſtum of a ſpheroid, lying with its axis perpendicular to the horizon; this line is marked thus ſeg. L *y*, the other line of ſegments marked ſeg. S *t*, is for finding the ullage of a caſk ſtanding.

Between theſe two ſegments ſlides a line of numbers with a double radius, marked at the end with N; and at each end of the ſlider there is a braſs ſtud for conveniency of moving them to and fro with your thumb.

Of the fourth face (or edge) of the rule.—5. On the oppoſite face of the rule (*fig.*9.) is placed a line of inches to 12 decimally divided; next to this lieth a line numbered with 1, 2, 3, &c. to 7, and at the end marked with ſpheroid, by help of which is found a mean diameter for a caſk, in form of the middle fruſtum of a ſpheroid; next under this is a line for finding the mean diameter of a caſk in form of the middle fruſtum of a parabolic ſpindle, called by gaugers, the ſecond variety of caſks; it is numbered 1, 2, 3, 4, 5, 6, and at its end is writ ſecond variety; next under this lieth a line for finding the mean diameter of a cask of the third variety, that is, a cask formed by fruſtums of two parabolic conoids abutting upon a common baſe, it is numbered 1, 2, 3, 4, 5, and at the end thereof is writ third variety.

Of the three ſliding-pieces, *fig.* 10. and 11.—6. The above are all the lines on the four ſides of the rule; but on the back-ſide of the two ſliding-peices is a line of inches from 13 to 36, when the two ſliding pieces are put end-ways together; and againſt that the correſponding gallons or hundred parts, that any ſmall tub, or ſuch like open veſſel (from 13 to 36 inches diameter) will contain at one inch deep; theſe are commonly called (by the gaugers) the ale area's; and by drawing out of the firſt ſlider, any open veſſel's diameter under 36 inches may be taken, and its area in ale gallons is ſhewn by inſpection; if the tub be more than 24 and leſs than 36 inches diameter, then pin the firſt ſlider faſt, and draw out the other ſlider, and you have the diameter in inches and decimal parts of an inch of that tub, with the ale area anſwering to that diameter by inſpection.

7. The inſide of the little ſlider marked N, O, (*fig.*12.) on the rule, is for reducing casks in the form of the fruſtum of a cone to a cylinder; as ſuppoſe the difference between the head and bung of a cask to be 5.3, ſeek this in the line of inches, and againſt it you will find 3.4, which add to the head diameter, and the ſum will be the mean diameter, that is, the diameter of a cylinder, (having the ſame length with the cask propoſed) equal to the ſaid cask.

Conſtruction of the lines on the ſliding-rule.—All the lines of numbers above deſcribed are made by one general rule, which is this; get a plate of braſs, or copper, &c. of what length you deſign your line to be; and thereon draw three parallel lines, for the better diſtinguiſhing the diviſions of the lines of numbers, and make a mark for the beginning of it; cloſe by theſe parallel lines draw ten other parallel lines, and divide this into ten equal parts; one of which ſubdivide into 100 equal parts, which makes it a diagonal ſcale of 1000 equal parts; being thus prepared, look into the table of logarithms for the number 200, and againſt it you will find the logarithm 2,301030, rejecting the characteriſtic 2, and alſo the three laſt figures on the right hand 030, becauſe the length of the radius is divided but into 1000 equal parts; take 301 from your diagonal ſcale in your compaſſes, and lay off that diſtance from the beginning of the line of numbers, and there place the figure 2 for the firſt prime. Again, to find the diviſion for the ſecond prime, look into the table of logarithms for the number 300, and you will find its logarithm to be 2,477121; reject

Fig. 1. Gauging

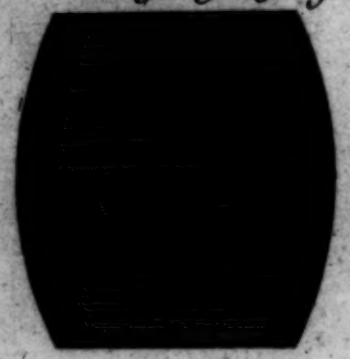

Fig. 2. Gauging.

Fig. 3. Gauging.

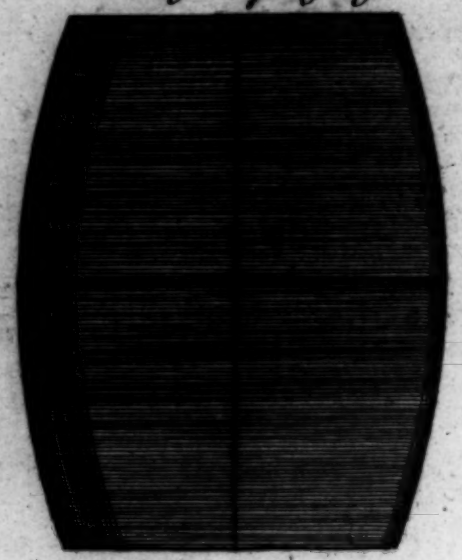

Fig. 4. Gauging.

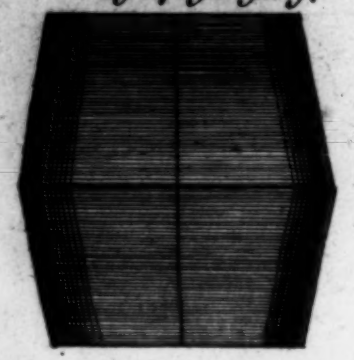

EVERARD'S SLIDING RULE

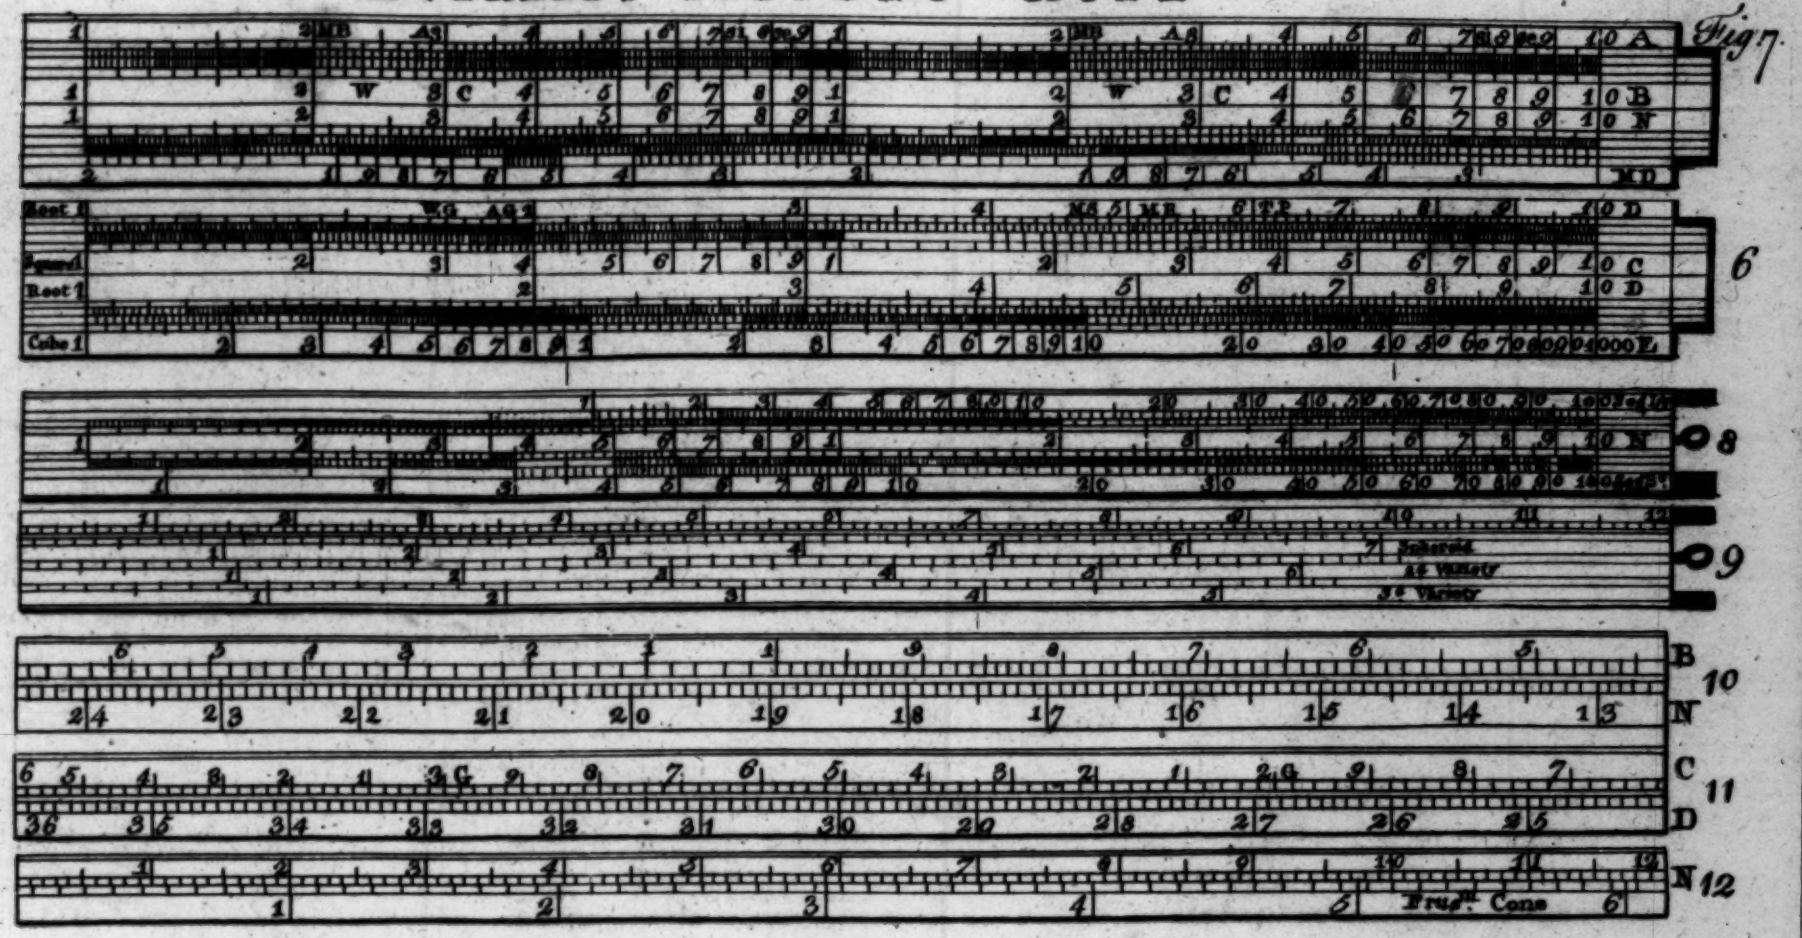

Fig. 5. Gauging

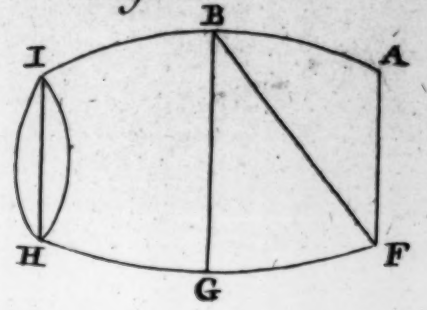
Fig. 13.



5 JA 59

reject the characteriſtic 2, and alſo the three laſt figures to the right hand, and take in your compaſſes from your diagonal ſcale, as before, the number 477, and lay off that diſtance from 1, at the beginning of the line of numbers, to 3 for the ſecond prime: and ſo by proceeding thus you will compleat all the prime numbers of one radius of your line of numbers.

The line called the malt depth, marked M D, is only the aforementioned line of numbers turned the contrary way, and is ſo ordered, that the number 1 on M D may exactly ſtand even with, or againſt M B on the line A, and then all the other diviſions will fall in their true places. By this means any number on A or B, multiplied by any number directly under it on the line M D, will always be equal to 2150.42, the number of inches in a malt buſhel.

The lines of ſegments marked ſeg. L *y*, and ſeg. S *t*, may be put on the ſliding-rule in the following manner: Let a cask be fixed upon, whoſe form agrees the neareſt to the moſt common ones in practice, and ſuppoſe both its bung, diameter, and length, divided into 100 equal parts, and planes drawn through each of them, viz. the firſt hundred (ſerving for the ſegment marked ſeg. S *t*) all parallel to the heads, and the ſecond hundred (ſerving for the ſegment marked ſeg. L *y*) all parallel to that plane which paſſes thro' the length of the cask. Now if the meaſure in gallons of each of theſe ſlices to be found, and the laſt always added to the ſum of the preceding ones, ſucceſſively, we ſhall have two tables of meaſures, one for the ſegment ſtanding, and the other for the ſegment lying. Theſe lines of ſegments may be otherwiſe put on as thus: take a cask, in form of the middle fruſtum of a ſpheroid, whoſe head diameter is 24,37, bung diameter 30,0, and length 44,85. This cask filled with water will contain juſt 100 gallons.

Now to find againſt what number on the line of numbers of the ſliding-place any diviſion of the line of ſegments, for a cask lying, muſt ſtand, proceed thus: let juſt one gallon be drawn off, then take the wet inches of the bung diameter, which reſerve; ſet the bung diameter to 100 on the intended line of ſegments, and againſt the reſerved wet inches place 99 on the line of ſegments. This being done, draw off again juſt one gallon, and take the wet inches of the bung diameter, againſt which, the ſlider ſtill remaining fixed as before, ſet 98; proceed in this manner, ſtill drawing off one gallon each time, and careſully taking the wet inches of the bung diameter, until you have compleated the line of ſegments for a cask lying.

The other ſegment line on the ſame face of the rule may be made in the ſame manner as this, by ſetting the aforeſaid veſſel upright, and making uſe of the length inſtead of the bung diameter. The conſtruction of the lines on the other edge of the rule for the four varieties of casks, are thus: 1. If there be a cask, in form of the middle fruſtum of a ſpheroid, half the difference of the ſquares of the bung and head diameters, added to the ſum and half ſum of the ſaid ſquares, divided by 3, will be the ſquare of the mean diameter, the ſquare root of which will be the mean diameter. 2. Three tenths of the difference of the ſquares of the bung and head diameters, added to the ſum and half ſum of the ſaid ſquares, and the whole divided by 3, will be the ſquare of the mean diameter of a cask of the ſecond variety. 3. To the ſum and half ſum of the ſquares of the bung and head diameters, add one tenth of the difference of the ſaid ſquares, which ſum, divided by 3, gives the ſquare of the mean diameter of a cask of the third variety. 4. And laſtly, from the ſum and half ſum of the ſquares of the bung and head diameters, ſubtract half the ſquare of the difference of the diameters, and the remainder divided by 3, will be the ſquare of the mean diameter of a cask of the fourth variety, or two equal fruſtums of a cone abutting upon a common baſe.

The inſide of the two ſliders are divided into inches, and every inch into ten equal parts; the other line, which lieth by the ſide of the line of inches, is the area in ale gallons and decimal parts of a gallon, which are made thus, viz. ſet unity on C to A G, the ale gauge point upon D, and againſt any diameter on D, is the area in ale-

gallons, and decimal parts of a gallon, upon C.

So as the rule now ſtands, it is a table for all diameters whatſoever.

Note, The gallons are put in large figures, and the tenths of a gallon in ſmaller figures; every tenth of a gallon is divided into five by a ſmall diviſion, every one of which ſignifies two hundred parts of a gallon. By which I ſee, as the rule now ſtands, that a tub of 19 inches diameter will hold one gallon and ſomething more, upon one inch of depth; and 24 inches diameter gives for the area 1 gallon and 6 tenths, 30 inches diameter gives 2 gallons and a half for the area, or content, at one inch deep.

Conſtruction of the Four-foot GAUGING-ROD.—This rod is uſually made of box-wood, and conſiſts of four rules, each a foot long, and about half an inch ſquare, joined together by three braſs joints, by which means the rod is rendered four feet long, when the four rules are quite opened, and but one foot in length when they are folded together.

On the firſt face of this rod is placed a line of inches (and ſometimes with it a line of ale areas) decimally divided, whoſe uſe is to take dimenſions neceſſary for gauging veſſels either for ale, wine, malt, &c.

Two diagonal lines are placed near the line of inches, one for ale, the other for wine.

The diagonal line of a cask is found by putting the rod in at the bung to the interſection of the head of the veſſel, with the ſtaves oppoſite to the bung hole; ſo B F, (plate LXVIII. *fig.* 13.) is the diagonal line.

By the bung, head, and length of a cask, we can find its diagonal line, as has been already ſhewn; whence, by having the contents of two ſimilar casks, and the diagonal of one of them given, we can find the diagonal line of the other; for as the content of any cask in ale or wine gallons, is to the cube of its diagonal, ſo is the content of any other cask (ſimilar to the former) to the cube of its diagonal, whoſe cube root is the diagonal required.

Lines adapted to the London casks are placed on the other faces of this four-foot gauging-rod, viz. 1. A line for a butt ſtanding. 2. For a butt lying; each of which contains 108 gallons, beer-meaſure. 3. A line for a hogſhead containing 54 gallons. 4. A line for the barrel of 36 gallons. 5. A line for a kilderkin of 18 gallons. 6. A line for a firkin of nine gallons. Then to gauge any of theſe casks, there is no more to do than to put in your rod perpendicular at the bung, &c. and if the cask is not full it gives you the quantity of liquor in the cask.

For the ſame purpoſe there are alſo lines put on four-foot gauging-rods for wine meaſure; as 1. A ton of 252 gallons. 2. A butt of 126 gallons. 3. A puncheon of 84 gallons. 4. A hogſhead of 63 gallons. 5. A tierce of 42 gallons. 6. A barrel of 31 ½ gallons. 7. A rundlet of 18 gallons. And laſtly, an anchor of 10 gallons. By theſe lines all brandies and oils are gauged.

Theſe lines for London casks are made, by ſetting the veſſel level, and pouring in one gallon of water, and then put the rod downright into the bung-hole (if it is a lying cask) or at the head (if a ſtanding cask) and where the ſurface of the water cuts the rod, make the diviſion for one gallon; then, pour in another gallon, and where the ſurface of the water cuts the rod, make diviſions for two gallons; proceed thus by pouring in one gallon ſucceſſively after another, and make diviſions at every place on the face of the rod, to which the water riſes, till the cask be full, and then you have the ſcale for that cask properly divided. Proceed in the ſame manner for every one of the London casks abovementioned, and all the lines will be finiſhed when figured.

Note, The diviſions for quarts, marked by dots on the rod, are made by pouring in a quart of water ſucceſſively, and that you may not be at a loſs to know what cask is in hand, the rod will ſhew you, for by meaſuring the depth of the bung, &c. if it cut 36, it is a barrel; if 18, it is a kilderkin, &c. and by the line for that cask you muſt take its ullage; that is, the quantity of liquor either drawn out, or remaining in the cask. For the uſes of the line of number, &c. ſee GUNTER's *Line*.

GAUNTLET, or GANTLET. See the article GANTLET.

GAVOTTA, or GAVOTTE, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains are played twice over; the first has usually four or eight bars, and the second contains eight, twelve, or more.

Tempi di GAVOTTA is when only the time or movement of a gavotte is imitated, without any regard to the measure, or number of bars or strains.

GAURS, in matters of religion, an ancient sect of the magicians in Persia. They have a suburb at Ispahan, which is called Gaurabad, or the town of the Gaurs, where they are employed only in the meanest and vilest drudgery: but they chiefly abound in Kerman, the barrenest province in all Persia, where the Mahometans suffer them to live with some freedom, and in the full exercise of their religion. Some years ago many of them fled into India, where their posterity remain to this day.

They are a poor harmless sort of people, zealous in their superstition, rigorous in their morals, and exact in their dealings: they profess the worship of one God alone, the belief of a resurrection, and a future judgment, and utterly detest all idolatry, though the Mahometans believe them to be the most guilty of it. It is true, they perform their worship before fire, for which they have an extraordinary veneration, as believing it to be the most perfect emblem of the deity. They have the same veneration for Zoroaster that the Jews have for Moses, esteeming him a prophet sent from God.

GAWSE, or GAWZE, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gawzes, and some with gold or silver flowers on a silk ground.

GAZONS, in fortification, pieces of fresh earth, covered with grass, and cut in form of a wedge, about a foot long and half a foot thick, to line the outsides of works made of earth, as ramparts, parapets, &c. The first bed of gazons is fixed with pegs of wood; the second bed should be so laid as to bind the former, by being placed over its joints; and so continued till the works are finished. Betwixt these beds it is usual to sow all sorts of binding herbs, in order to strengthen the rampart.

GEERS, in country-affairs, the trappings and other harness belonging to draught-horses or oxen.

GEESE, in ornithology. See GOOSE.

GEHENNA, a term mentioned in several parts of Scripture, which our English translators have rendered hell. See HELL.

GELATINOUS, in pharmacy and medicine, any thing approaching to the glutinous consistence of a gelatina, or jelly.

GELD, in our old customs, a Saxon word signifying money, or tribute: also a compensation for some crime committed. See the article GILD.

GELDER-ROSE, the name by which some call the opulus, or water-elder.

GELDING, the operation of castrating any animal, particularly horses.

This operation consists in cutting out the testicles; in performing which, three things are to be observed: first, regard is to be had to their age; next, to the season of the year; and, lastly, to the state of the moon. For the first, if the operation is to be performed on a colt; he may be gelded at nine or at fifteen days old, if the testicles be come down, in regard the sooner he is gelt the better it will be for his growth, shape, and courage; though a horse may be gelt at any age, if proper care be taken in the cure. As for the second, the best time is about April or May, or else about the latter end of September. And for the third, the wane of the moon is the fittest time for performing this operation.

The manner of gelding is as follows: the beast being cast down on some soft place, the operator takes the stones between his foremost and his great finger, and slitting the cod, presses the stones forth: then taking a pair of nippers, made very smooth, either of steel, box, or brasil-wood, he claps the strings of the stones between them, very near to where the stones are set on, and presses them so hard, that there may be no flux of the blood; then, with a thin, drawing cauterizing iron, made red-hot, sears away the stone.

This done, he takes a hard plaster made of rosin, wax, and washed turpentine, well dissolved together, and melts it on the head of the strings: that being done, he sears them, and melts more of the salve, till such time as he has laid a good thickness of it upon the strings.

This being done to one stone, the nippers are loosened, and the like is done to the other; and the two slips of the cod are then filled with white salt, and the outside of the cod is anointed with hogs-grease; and thus they let him rise, and keep him in a warm stable, without tying him up.

If he swells much in his cods or sheath, they chase him up and down; and make him trot an hour in a day, and he soon recovers.

The manner of gelding a hog is as follows: the operator, after having made two cross slips, or incisions, on the midst of the stones, presses them out, and anoints the sore with tar. But another more general method, yet somewhat more dangerous, if not well done, is first to cut the stone on the top, and after having drawn the one forth, the operator puts in his fingers at the same slip, and, with a lancet, cuts the skin between the two stones, and by that slit presses out the other stone. Then having cleansed out the blood, he anoints the part with fresh grease: and thus there is but one incision made in the cod. Boar-pigs ought to be gelt about six months old; yet they are commonly gelded about three weeks or a month old.

GELDING *of a Lamb* may be performed from the age of three days to three weeks or more, in the following manner: one is to hold the lamb between his legs, or in his lap, and turn him on his back, holding his fore-feet upright together (but if any black spots are seen in his flank, he must not be cut at all); then the cutter holding the tip of the cod in his left hand, cuts the lap of it an inch quite away; which done, he, with the foremost fingers and thumbs of both hands, should softly slip down the cod over the stones, to the belly, and with his teeth, holding the left stone in his mouth, he draw it softly out the length of the string; after which he is to draw out the other stone in the same manner; then he spits in the cod, and anoints the lamb's flanks with fresh grease, and so lets him go, and keeps stirring him up and down for two or three hours.

GEM, *Gemma*, in natural history, a common name for all precious stones, of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, pellucid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance, giving fire with steel, not fermenting with acid menstruums, and very difficultly calcinable in the fire.

The bodies composing the class of semipellucid gems, are stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter debased by earth: however, they are but slightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

Many authors, not only among the ancients but the moderns, are full of the virtues and medicinal properties of precious stones; but their reputation, in this respect, is now greatly fallen.

Imitation or counterfeiting of GEMS *in Glass.*—The art of imitating gems in glass, is too considerable to be passed without notice; some of the leading compositions therein, we shall briefly mention upon the authority of Neri. See GLASS.

These gems are made of pastes, and are no way inferior to the native stones, when carefully made and well polished, in brightness or transparence, but want their hardness. See the article PASTE.

The general rules to be observed in making the pastes are these. 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work

work, as will bear the fire well. 3. That the powders be prepared on a porphyry ſtone, not in a metal mortar, which would communicate a tinge to them. 4. That the juſt proportion in the quantity of the ſeveral ingredients be nicely obſerved. 5. That the materials be all well mixed, and if not ſufficiently baked the firſt time, to be committed to the fire again, without breaking the pot: for if this be not obſerved, they will be full of bliſters and air-bladders. 6. That a ſmall vacuity be always left at the top of the pot, to give room to the ſwelling of the ingredients.

To make paſte of extreme hardneſs, and capable of all the colours of the gems, with great luſtre and beauty.—Take of prepared cryſtal, ten pounds; ſalt of polverine, ſix pounds; ſulphur of lead, two pounds; mix all theſe well together into a fine powder; make the whole with common water into a hard paſte; and make this paſte into ſmall cakes of about three ounces weight each, with a hole made in their middle; dry them in the ſun, and afterwards calcine them in the ſtraighteſt part of a potter's furnace. After this, powder them, and levigate them to a perfect fineneſs on a porphy-ſtone, and ſet this powder in pots in a glaſs-furnace to purify for three days: then caſt the whole into water; and afterwards return it into the furnace, where let it ſtand fifteen days, in which time all foulneſs and bliſters will diſappear, and the paſte will greatly reſemble the natural jewels. To give this the colour of the emerald, add to it braſs thride calcined; for a ſea-green, braſs ſimply calcined to a redneſs; for a ſapphire, add zaffer, with manganeſe; and for a topaz, manganeſe and tartar. All the gems are thus imitated in this by the ſame way of working as the making of coloured glaſſes; and this is ſo hard, that they very much approach the natural gems.

The colour of all the counterfeit gems made of the ſeveral paſtes, may be made deeper or lighter, according to the work for which the ſtones are deſigned; and it is a neceſſary general rule, that ſmall ſtones for rings, &c. require a deeper colour, and large ones, a paler: beſides the colours made from manganeſe, verdigreaſe, and zaffer, which are the ingredients commonly uſed, there are other very fine ones which care and ſkill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from braſs or copper; a ſky-colour from ſilver; and a much finer one, from the granates of Bohemia.

GEMARA, in Jewiſh antiquity, a collection of deciſions and determinations on the law, wrote after the Miſchna was completed.

It was called gemara, or perfection, becauſe it was conſidered as ſo perfect an explication of the law, that after it no further additions could be made, or any thing more deſired. It is otherwiſe called the Talmud. See TALMUD.

GEMELLUS, in anatomy, the name of two muſcles, both of which are ſmall, flat, and narrow, and ſituated almoſt tranſverſely one above the other, between the tuberoſity of the iſchium and the great trochanter, immediately below the pyriformis, and parted by the tendon of the obturator internus.

The ſuperior and ſmalleſt gemellus is fixed to the lower part of the ſpine of the iſchium, to the ſuperior part of the ſmall iſchiatic notch, and is continued under the acetabulum, where it is bent downwards. The inferior and largeſt gemellus is fixed to the ſuperior and back part of the tuberoſity of the iſchium, and bending upwards towards the other line, together with it forms a ſort of irregular ſemicircle.

GEMINATED COLUMN. See the article COLUMN.

GEMINI, the twins, in aſtronomy, one of the twelve ſigns of the zodiac, the third in order, beginning with aries. See the articles SIGN and ZODIAC.

This conſtellation, according to different authors, contains from 24 to 89 ſtars. It is repreſented by the figure of two twin-children, looking each other affectionately in the face, and ſuppoſed to be Caſtor and Pollux.

GEMMA, *Gem*, in natural hiſtory. See the article GEM.

Sal GEMMÆ is the pureſt and fineſt foſſile ſalt, and an extremely bright and beautiful foſſil. It is conſiderably hard and firm, and at leaſt as pellucid as rock cryſtal; but is frequently coloured throughout with a milky-white, which takes off greatly from its luſtre; and as cryſtal is liable to be tinged with red, green, and yellow, ſo as to reſemble rubies, ſapphires, emeralds, and topazes, ſo this ſalt is ſometimes tinged with theſe ſeveral colours; but rarely preſerves the tranſparency of cryſtal under the ſame circumſtances. See the article SALT.

GENDARMES, or GENS D'ARMES, in the French armies, a denomination given to a ſelect body of horſe, on account of their ſucceeding the ancient gendarmes, who were thus called from their being completely cloathed in armour.

The king's body guards, the light horſe of the royal houſe, and the muſqueteers, are at preſent reputed to belong to the gendarmerie.

The grand gendarmes are a troop compoſed of about two hundred and fifty gentlemen, who guard the king's perſon. The king himſelf is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three enſigns, three guidons, and other officers. There are beſides theſe, gendarmes of the queen, the daupbin, &c.

GENDER, *Genus*, among grammarians, a diviſion of nouns, or names, to diſtinguiſh the two ſexes. See NOUN and SEX.

This was the original intention of gender; but, afterwards, other words which had no proper relation, either to the one ſex or the other, had genders aſſigned them, rather out of caprice than reaſon, which is at length eſtabliſhed by cuſtom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus *arbor*, in Latin, is feminine; but *arbre*, in French, is maſculine: and *dens*, in Latin, is maſculine; but *dent*, in French, is feminine. Nay, a gender has ſometimes changed in the ſame language, according to time and occaſion. Thus *aluus*, according to Priſcian, was anciently maſculine, but afterwards became feminine; and *navire* was anciently feminine in French, but is now maſculine. In Engliſh we have no genders; indeed we expreſs the difference of ſex by different words; as boar, ſow; boy, girl, &c. We have alſo twenty-four feminines diſtinguiſhed from the males by varying the termination of the female into eſs; as actor, actreſs; prince, princeſs; heir, heireſs, &c. and we have a few words in which the feminine is diſtinguiſhed from the maſculines by the termination ix, as executor, executrix; adminiſtrator, adminiſtratrix, &c. which is all our language knows of any thing like genders.

The eaſtern languages, as well as the vulgar languages of the weſt, have only two genders, the maſculine and the feminine. The Greek and Latin have beſides, the neuter, common, and doubtful gender. This laſt indeed is not common, for it properly belongs only to the names of ſome animals, which are promiſcuouſly joined both to maſculine and feminine adjectives, to expreſs their male or female, as *bos*, *canis*, *ſus*, &c. They have alſo the epicœne gender, which is not a different one, but ſerves promiſcuouſly for either; including both the kinds under one ſingle gender and termination: thus *vulpes*, a fox, though it ſignifies either the male or female, is really of the feminine gender, in Latin. And ſo *cuſtodiæ*, watchmen or centinels, are really feminine, though they ſignify men. This is common to all languages that have them. The Latin and Greek, in the neuter gender, do not regard them, having no relation to the male or female ſex, but what fancy gives them, and the termination of certain words.

The Oriental languages frequently neglect the uſe of genders; and the Perſian language has none at all, which is no diſadvantage; the diſtinction of genders being entirely uſeleſs.

GENEALOGY, γενεαλογια, an enumeration of a ſeries of anceſtors; or a ſummary account of the relations and alliances of a perſon or family, both in the direct and collateral line.

GENERAL TERMS, among logicians, thoſe which are made the ſigns of general ideas.

All things that exiſt, Mr. Locke obſerves, being particulars, it might be expected that words ſhould be ſo too in their ſignification: but we find it quite contrary; for moſt

moſt of the words that make all languages are general terms. This is the effect of reaſon and neceſſity. For,

Firſt, It is impoſſible that every particular thing ſhould have a diſtinct name, becauſe it is impoſſible to have diſtinct ideas of every particular thing, to retain its name, with its peculiar appropriation to that idea.

Secondly, It would be uſeleſs, unleſs all could be ſuppoſed to have theſe ſame ideas in their minds: for names applied to particular things, whereof I alone have the ideas in my mind, could not be ſignificant or intelligible to another, who is not acquainted with all thoſe particular things which had fallen under my notice.

Thirdly, It would be of no great uſe for the improvement of knowledge; which, though founded in particular things, enlarges itſelf by general views; to which things, reduced into ſorts under general names, are properly ſubſervient.

In things where we have occaſion to conſider and diſcourſe of individuals and particulars, we uſe proper names: as in perſons, countries, cities, rivers, mountains, &c. Thus we ſee that jockeys have particular names for their horſes, becauſe they often have occaſion to mention this or that particular horſe, when he is out of ſight.

Afterwards, obſerving that a great many things reſemble each other in ſhape, and other qualities, we frame a general idea that takes in only the qualities in which thoſe many particulars agree; and to this idea we give the name *man*, for example, in which there is nothing new; that which is peculiar to each individual being left out, and only what is common to all retained. And thus we come to have a general idea, and a general name. By the ſame method the mind proceeds to more general notions and names, as thoſe of animal, ſubſtance, being, thing, and ſuch univerſal terms as ſtand for any ideas whatſoever.

As to the ſignification of general words, it is evident they do not barely ſignify one particular thing; neither do they ſignify a plurality. But they ſignify a genus, kind, or ſort of things. See the articles ABSTRACTION and GENUS.

GENERAL *of an Army*, in the art of war, he who commands in chief. See ARMY.

A general ought to be a man of great courage and conduct, to have great experience, and to be of good quality. His conduct appears in eſtabliſhing his magazines in convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in ſubſiſting them; and in knowing how to take the moſt advantageous poſts, either for fighting or ſhunning a battle. His experience inſpires his army with confidence, and an aſſurance of victory; and his quality, by creating reſpect, augments his authority. By his liberality he gets intelligence of the ſtrength and deſigns of the enemy, and by this means is enabled to take the moſt ſucceſsful meaſures. A general ought likewiſe to be fond of glory, to have an averſion to flattery, to render himſelf beloved, and to keep a ſtrict diſcipline.

The office of a general is to regulate the march and encampment of the army; in the day of battle to chooſe out the moſt advantageous ground; to make the diſpoſition of the army; to poſt the artillery; and where there is occaſion, to ſend his orders by his aids de camp. At a ſiege he is to cauſe the place to be inveſted; to order the approaches and attacks; to viſit the works, and to ſend out detachments to ſecure his convoys.

GENERAL is alſo uſed for a particular march, or beat of drum; being the firſt which gives notice, commonly in the morning early, for the infantry to be in readineſs to march.

GENERATING *Line*, or *Figure*, in geometry, is that which by its motion produces any other plane or ſolid figure. Thus, a right line moved any way parallel to itſelf, generates a parallelogram; round a point in the ſame plane, with one end faſtened in that point, it generates a circle. One entire revolution of a circle, in the ſame plane, generates the cycloid; and the revolution of a ſemi-circle round its diameter, generates a ſphere, &c. See the articles CYCLOID, SPHERE, &c.

GENERATION, *Generatio*, in phyſiology, the act of procreating and producing a thing which before was not; or, according to the ſchoolmen, it is the total change or converſion of one body into a new one, which retains no marks of its former ſtate. Thus, we ſay, fire is generated, when we perceive it to be where before there was only wood, or other fuel: in the ſame manner a chick is ſaid to be generated, when we perceive it where before there was only an egg; or the egg is changed into the form of a chick.

In generation there is not properly any production of new parts; but only a new modification, or manner of exiſtence, of the old ones.

When almighty God, ſays Dr. Blair, created the world, he ſo ordered and diſpoſed of the *materies mundi*, that every thing produced from it ſhould continue ſo long as the world ſhould ſtand. Not that the ſame individual ſpecies ſhould always remain; for they were in proceſs of time to periſh, decay, and return to the earth from whence they came; but that every like ſhould produce its like, every ſpecies produce its own kind, to prevent a final deſtruction of the ſpecies, or the neceſſity of a new creation. For which end he laid down certain regulations, by which each ſpecies was to be propagated, preſerved, and ſupported, till, in order and courſe of time, they were to be removed hence: for without that thoſe very beings, which were created at firſt, muſt have continued to a final diſſolution of all things; which almighty God of his infinite wiſdom, did not think fit. But that he might ſtill the more manifeſt his omnipotence, he ſet all the engines of his providence to work, by which one effect was to produce another, by means of certain laws or rules, laid down for the propagation, maintenance, and ſupport of all created beings. This his divine providence is called nature, and theſe regulations are called the laws or rules of nature, by which it ever operates in its ordinary courſe; and whatever recedes from that, is ſaid to be preternatural, miraculous, or monſtrous.

GENERATION *of Animals*. According to Ariſtotle, the males contain the principle, and the females the matter of generation: for though both were furniſhed indeed, with a ſeminal liquor, yet the ſemen of the males alone was prolific. The moderns, on the other hand, as well thoſe who contend for the ſyſtem of generation from eggs, as they who adopt that of the animalcules in the male ſeed, pretend that females have no ſuch ſeminal liquor at all, and that what was commonly taken for it was ſome other animal fluid.

There are great and many difficulties which attend the moſt plauſible account of the firſt formation of the parts of an animal, and the beginning of motion in its fluids: for though both reaſon and experience convince us, that all the parts of an animal did exiſt before generation; yet how this matter comes to aſſume ſo very different a form, as that of an embryo, is by no means agreed on.

Harvey is of opinion, that all females are furniſhed with eggs, and that the embryoes, or young animals, are formed in the ſame manner as a chick in the egg of any bird. Generation, according to this celebrated phyſician, is effected wholly by means of the uterus, or womb; which conceives the fœtus by a kind of contagion communicated to it by the male-ſeed, much in the ſame way as the load-ſtone communicates magnetiſm to iron. This contagion, he thinks, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus he acknowledges is the only part that is capable of conceiving the fœtus, juſt as the brain is alone capable of forming ideas and notions. Agreeably to this doctrine of Harvey, Steno, and other anatomiſts, have pretended to diſcover certain eggs in the ovaries or teſticles of women; which Mr. Buffon denies to be the caſe, affirming, that there are no ſuch eggs to be found in the teſticles or ovaries of women.

We cannot enter into a detail of the reaſonings for and againſt the ſyſtem of generation from eggs, and ſhall therefore only obſerve, that its advocates pretend to have diſcovered eggs in all the females on which they made obſervations; that the largeſt of thoſe found in women did

did not exceed the bigneſs of a pea; that they are extremely ſmall in young girls under fourteen, but that age and commerce with men makes them grow larger; that there are more than twenty ſuch eggs in each ovary or teſticle; that they are fecundated in the ovary by the ſpirituous and volatile part of the male-ſeed; that they afterwards are detached and fall into the uterus through the Fallopian tubes; that here the fœtus is formed of the internal ſubſtance of the egg, and the placenta of the exterior part. See the article FOETUS.

Leewenhoek is the author of another ſyſtem of generation, from animalcules in the male ſeed. He tells us, he diſcovered many thouſands of theſe in a drop leſs than a grain of ſand. They are found in the ſemen of all males whatever, but not in that of females; and are ſo ſmall, that 3,000,000,000 of them are not equal to a grain of ſand, whoſe diameter is but the hundredth part of an inch. When any of theſe animalcules gets into an egg, fit to receive it, and this falls into the womb through the Fallopian tubes, the humours which diſtil through the veſſels of the womb, penetrating the coats of the egg, ſwell and dilate it, as the ſap of the earth does ſeed thrown into it. The placenta begins to appear like a little cloud, upon one ſide of the external coat of the egg; and, at the ſame time, the ſpine of the embryo-animalcule is grown ſo big, as to become viſible; and a little afterwards, the cerebrum and cerebellum appear like two bladders; and the eyes ſtand next goggling out of the head; then the beating of the heart, or punctum ſaliens, is plainly to be ſeen; and the extremities diſcover themſelves laſt of all.

Theſe animalcules are of different figures, ſome like tadpoles, and others like eels. In the ſemen of a man, and in that of a dog, there have been diſcovered two different kinds of them, the one ſuppoſed to be males, and the other females. Some even pretend to have ſeen animalcules diſengage themſelves from the membranes that ſurround them; and that they then appeared perfectly like men, with legs, arms, &c. like thoſe of the human body.

All the advocates for the ſyſtem of generation from animalcules ſtrongly oppoſe that from eggs. They contend, that theſe animalcules cannot be looked upon as the inhabitants of the ſemen, ſince they were of greater extent than the liquor itſelf, not to mention that no ſuch animals are found in any other liquors of the body; and ſince females have nothing ſimilar to theſe animals, they think it manifeſt that the prolific principle reſides in males. When they are aſked to what purpoſe ſerves ſuch an immenſe profuſion of human animalcules, they anſwer, that it is agreeable to the ordinary courſe of nature, both in the animal and vegetable part of the creation. They likewiſe ſtrengthen their ſyſtem, by alledging the many examples we have of ſimilar transformations in the inſect-claſs of animals, which, from caterpillars and ſmall worms, become winged animals of the butterfly, or fly-kinds.

By this ſyſtem, ſays Mr. Buffon, the firſt woman cannot be ſaid to have contained the whole race of mankind, as being all, according to it, the true poſterity of the firſt man, and in their animalcule-ſtate contained only in him. On this principle he proceeds to invalidate the ſyſtem of generation from animalcules: for ſuppoſing the ſize of a man to be 1, then will that of one of the ſpermatic animalcules be $\frac{1}{1000000000}$; and as a man is to an animalcule of the firſt generation in the ſame ratio, that this animalcule is to an animalcule of the ſecond generation, it follows that this laſt will be expreſſed by the fraction $\frac{1}{1000000000000000000}$. In this manner he computes the ſize of the animalcules of ſeveral generations, all ſuppoſed to be living animals, notwithſtanding that their minuteneſs exceeds the power of imagination to conceive; and then tells us, that the ſyſtem of generation from eggs is liable to the ſame objections, whereof the detail may be ſeen in his *Hiſt. Natur. tom.* 2. *p.* 157, *& ſeq.*

As to Buffon's own ſyſtem, he thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; that theſe molecules aſſume ſucceſſively different forms, and are put into different motions, according to the circumſtances they are in; but that they are much more numerous in the ſeminal liquors of both ſexes, and the ſeeds of plants, than in other parts; that theſe organic molecules make the matter of nutrition; that this matter is always active, and tends to organization, forming itſelf into different ſhapes, according to the moulds it meets with. When the quantity of this organic matter is but ſmall, as in man, and moſt large animals, generation only takes place at the age of maturity, and even then the number of animals produced is but ſmall. The caſe is juſt the reverſe in animals which abound with this matter, as in fiſhes, and moſt birds.

With reſpect to the generation of mankind, the ſame author thinks it a certain fact, that the male-ſeed is received into the womb of the woman; and that, for this purpoſe, it is highly probable the internal orifice opens during the act of coition. The female-ſeed alſo makes its way into the womb, where being mixed with that of the male, they both together contribute to the formation of the fœtus; which is either male or female, according as the ſeed of the man or woman abounds moſt with organic molecules; and the infant reſembles either the father or mother, according to the different combinations of theſe molecules. Both theſe ſeminal liquors he thinks equally active in the formation of the fœtus, and that they fix and counterballance each other; the molecules of each parent being thereby determined to form ſimilar parts to thoſe of the individual that furniſhed them, as the head, trunk, arms, legs, &c. He thinks the molecules proceeding from the genital parts fix themſelves firſt; and that the other molecules arrange themſelves ſucceſſively round theſe, in the ſame order which they before occupied in the parent. When a great quantity of the ſeminal liquors of both ſexes is received into the womb, there are formed different ſpheres of attraction in different parts of theſe liquors; the conſequence of which is, that ſeveral fœtuſes are formed at the ſame time. See VEGETATION.

Nearly a-kin to Mr. Buffon's ſyſtem is that of Mr. Maupertuis, which he has explained in his *Venus Phyſique*. He obſerves, that all the variety, obſervable among mankind, may have been accidental at firſt; but being once eſtabliſhed in the conſtitution of the parents, they become natural to their poſterity. To illuſtrate this, he gives an inſtance of a ſexdigitary family at Berlin, who had ſix fingers, or ſix toes, and frequently both; and that this peculiarity was tranſmitted equally by the father and mother, but was loſt by alliances with thoſe who had but the uſual number of fingers or toes.

He farther obſerves, that moſt animals, excepting mankind, have ſtated ſeaſons for procreation, and that the females go with young ſome a longer, others a ſhorter time. Mares go from eleven to twelve months; cows and hinds go nine months, as do alſo women; foxes and wolves, five months; and bitches go only ſeven weeks; cats nine weeks; and rabbits but thirty-one days. Moſt birds are hatched in twenty-one days; the canary birds, and ſome others, are hatched in thirteen or fourteen days. It appears, therefore, that there is an endleſs variety in the time and manner of the generation of animals.

Thoſe who deſire a more full account of theſe ſyſtems of generation may conſult Harvey, Leewenhoek, Buffon, &c.

Parts of GENERATION. The parts of generation, in men, are the teſticles, vaſa deferentia, veſiculæ ſeminales, and penis. See the article TESTICLE, &c.

Thoſe, in women, are the pudendum or vulva, the clitoris, nymphæ, vagina, uterus or womb, ovaries, and Fallopian tubes. See the articles PUDENDUM, CLITORIS, &c.

GENERATION *of Fiſhes.* The opinion of moſt naturaliſts, that the female fiſhes firſt depoſit their ſpawn, and that the males afterwards eject the ſemen upon it, is denied by Linnæus; who thinks it impoſſible that the eggs of any animal ſhould be impregnated out of its body. He thinks it much more probable, that the males always eject their ſemen ſome time before the females depoſit their ſpawn; and that, by ſwallowing this ſemen, the ſpawn is impregnated in the body of the fiſh. Nay, he tells us, that he himſelf ſaw three or four females, in the ſpawning time, gather about the male, and greedily

ſwallow the ſemen he ejected. This he obſerved in ſome ſpecies of the eſox, pearch, and eſpecially the cyprinus; but he recommends farther enquiry to be made on this ſubject.

GENERATION *of Inſects* is now certainly known to be from eggs; which the female depoſits in places, where, at a proper ſeaſon, they are hatched into animals like their parents; or into maggots, or worms, which, after ſeveral tranſformations, at laſt appear in the form of their parents.

GENERATION *of Plants.* The impregnation of the female palm-tree by the male, has been known in the moſt ancient times. Herodotus, the father of hiſtory, tells us, that the Greeks called ſome of theſe trees male, the fruit of which they bound to the other kind, which bears dates; that the ſmall flies, wherewith the male abounded, might aſſiſt in ripening the fruit of the female-tree. The remote age in which Herodotus wrote, ſufficiently apologizes for his believing, that what was really brought about by the farina fœcundans of the male flower, was to be attributed to the inſects frequently found therein, and which perhaps frequently carry this farina from the male to the female. The proceſs of impregnation, according to Theophraſtus, was this: while the male plant was in flower, they cut off a branch of theſe flowers, and ſcattered the duſt and down therein upon the flowers of the female plant; by which means the female did not caſt her fruit, but preſerved them to maturity. This has been lately verified at Berlin, where a female palm-tree bore fruit for many years; but the fruit never ripened, and when planted, did not vegetate, merely becauſe there was no male palm in the place: for having procured a branch of male flowers from Leipſic, twenty German miles from Berlin, they ſuſpended it over the female flowers of their tree; and the experiment ſucceeded ſo well, that the female tree produced more than an hundred perfectly ripe fruit; and the experiment being repeated, it bore above two thouſand ripe fruit, which being planted produced young trees.

It is in the flowers of vegetables only, that the parts ſubſervient to generation are produced; and theſe flowers are either male, female, or hermaphrodite. Male flowers are thoſe poſſeſſed of the organs of generation, analogous to the male parts of animals; ſuch are the ſtamina and apices, called, by Linnæus, filaments and antheræ. The female flowers are only endowed with parts like thoſe, which perform the office of generation in females; and theſe are the piſtil and its appurtenances, which Linnæus divides into three parts, the germen, ſtyle, and ſtigma. The hermaphrodite flower, which conſtitutes the great bulk of the vegetable creation, is poſſeſſed of all theſe parts in itſelf, and is therefore capable of propagating its ſpecies without any foreign aſſiſtance; which, by many inconteſtable experiments, it has been found neither the male nor female flower ſimply is able to do. The impregnation of hermaphrodite flowers may be performed within their own calyx; but before a ſeparate female flower can be ſo, the farina fœcundans of the male flower muſt neceſſarily be conveyed to it thro' the circumambient air; which is the reaſon why the quantity of the produce of ſuch plants is much more precarious, than that of plants which have hermaphrodite flowers: for if, during the flowering of theſe ſeparate male and female plants, the weather proves either very wet or ſtormy, their produce of fruit will be very inconſiderable, from the ſpoiling or haſty diſſipation of the male farina. Thus, independent of froſts, the fruit of the nut and filbert-tree will be moſt numerous in thoſe years, in which the months of January and February are the leaſt ſtormy and wet, becauſe at that time their flowers are produced. For the ſame reaſons, a ſtormy or wet May deſtroys the cheſnuts; and the ſame weather, in July, prodigiouſly leſſens the crop of maiz, or Indian corn, as its ſpikes of male-flowers ſtand lofty, and at a conſiderable diſtance from the female.

Some of the more ſkilful modern gardeners put in practice, with regard to melons and cucumbers, the very method mentioned by Theophraſtus two thouſand years ago, in regard to the palm tree. As theſe plants, early in the ſeaſon, are in this climate confined to frames and glaſſes, the air in which they grow is more ſtagnant than the open air; whereby the diſtribution of the farina fœcundans, ſo neceſſary towards the production of the fruit for the propagation of the ſpecies, is much hindered. To obviate the inconvenience thence ariſing, they collect the male flowers when fully blown; and preſenting them to the female ones by a ſtroke of the finger, they ſcatter the farina fœcundans therein, which prevents the falling of the fruit before it is ripe.

By far the greater part of plants produce hermaphrodite flowers; but ſome there are which have ſeparate male and female-flowers growing from the ſame root, as maiz, nettles, box, elm, birch, oak, beech, hazel, hornbeam, plane-tree, pine, fir, cypreſs, cedar, melons, cucumbers, gourds, and ſeveral others; in many of theſe, the male and female flowers ſtand at a conſiderable diſtance. There are other plants which produce their neceſſary organs upon different roots, as the palm-tree, hops, the willow-tree, miſletoe, ſpinach, hemp, poplar, french and dog's mercury, the yew-tree, juniper, and ſeveral others. Among theſe, the valiſnieria of Linnæus, as to the manner in which its male-flower impregnates the female, is one of the moſt ſingular prodigies in nature. It grows in rivulets, ditches, and ponds, in many parts of Europe. The male plant, which is continually covered with water, has a ſhort ſtalk, upon the top of which its flowers are produced. As this top never reaches the ſurface of the water, the flowers are thrown off from it, and come unopened to the ſurface of the water; where, as ſoon as they arrive, by the action of the air, they expand themſelves, and ſwim round the female flowers, which are blown at the ſame time. Theſe laſt have a long ſpiral foot-ſtalk, by which they attain the ſurface of the water, and remaining there in flower a few days are impregnated by the male-flowers detached from the ſtalk at the bottom.

It is obſervable, that the operations of nature are carried on moſt uſually by certain general laws, from which however ſhe ſometimes deviates. Thus almoſt all plants have either hermaphrodite flowers, or male and female flowers, growing from the ſame root, or male and female flowers from different roots; but there are a few of another claſs, which from the ſame root furniſh either male hermaphrodite flowers, or female and hermaphrodite ones: of this kind are the mulberry-tree, the muſa, or plantain-tree, white hellebore, pellitory, arrach, the aſh-tree, and a few others.—*Watſon*, in Phil. Tranſ. Vol. 47. p. 169—183.

Some object to this theory of the generation of plants, from having obſerved ſome plants, which were termed female, growing ſingly; and though at a very great diſtance from any male plants of the ſame kind, producing perfect fruits, which grew when ſown. Mr. Miller tells us, he himſelf was ſtaggered in his opinion, on having obſerved a female plant of white briony, which grew ſingly in a garden, where there were no other plants of the ſame kind; which, nevertheleſs, for ſeveral years, produced berries, which grew and flouriſhed perfectly well. This put him upon examining the plant more carefully than he had done before, when a great many male-flowers were found intermixed with the female ones; and he adds, that he has frequently obſerved the ſame in many other plants, which are generally male and female in diſtinct plants, yet have ſometimes both ſexes on the ſame plant.

From what has been ſaid, it appears very plain, that the embryo of the female flower muſt be impregnated by the farina fœcundans, or male duſt, in order to render the fruit perfect; but how, or in what manner, it is performed, is what we can only gueſs at; ſince, in the generation of animals, our greateſt naturaliſts differ widely, as has been ſhewn above, in their opinions concerning the particular method how it is performed. If, ſays the reverend Dr. Hales, I may be allowed to indulge conjecture, I would propoſe it to the conſideration of naturaliſts, whether, from the manifeſt proof we have that ſulphur attracts air, a hint may not be taken to enquire whether this may not be the primary uſe of the farina fœcundans, to attract and unite with itſelf, elaſtic or other refined active particles. That this farina abounds with ſulphur, and that a very refined ſort, is probable from the ſubtile oil which chemiſts obtain from the chives of ſaffron: and if this be the uſe of it, was it poſ-

ſible

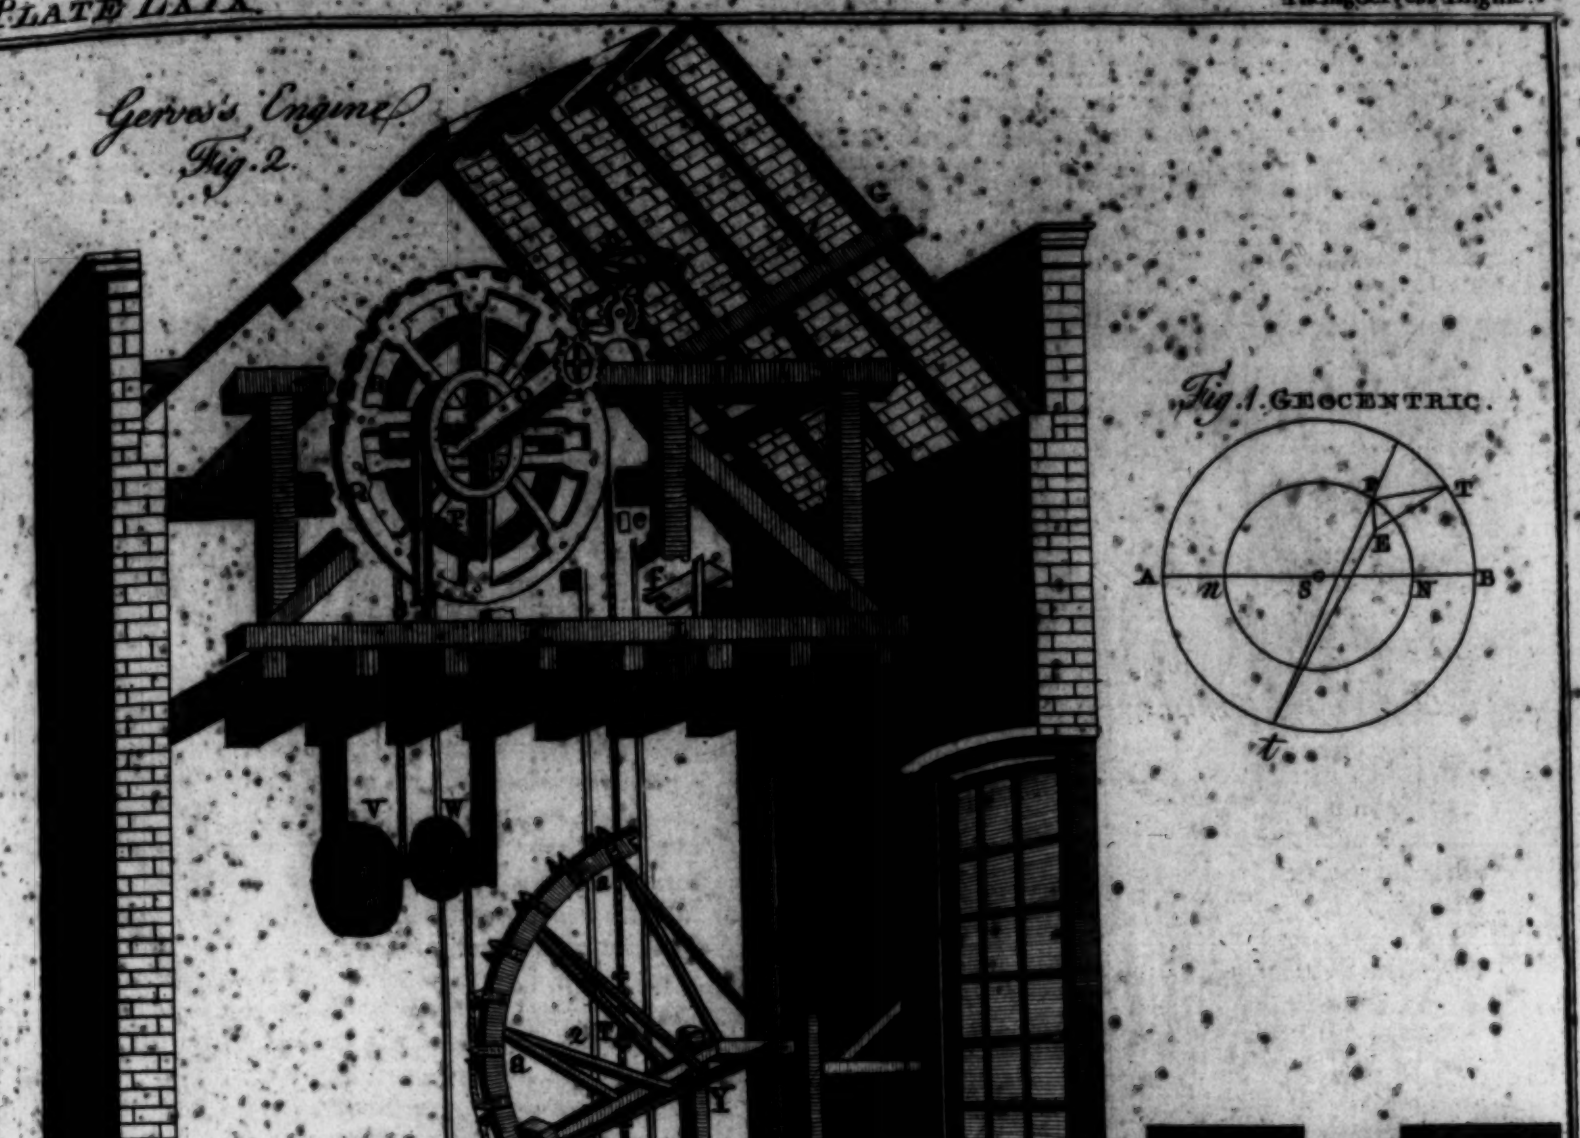

Fig. 1. GEOCENTRIC.

5 JA 59

ſible that it could be more aptly placed than on the ſlender points of the ſtamina, where it might eaſily, with the leaſt breath of wind, be diſperſed in the air; thereby ſurrounding the plant, as it were, with an atmoſphere of ſublimed ſulphureous pounce! Theſe uniting with particles of air, may, perhaps, be inſpired at ſeveral parts of the plant, and eſpecially at the piſtil, and be thence conveyed to the capſula ſeminalis. And if to theſe united ſulphureous and aerial particles, we ſuppoſe ſome particles of light to be joined (for Sir Iſaac Newton has found that ſulphur attracts light ſtrongly); then the reſult of theſe three by far the moſt active principles in nature will be a punctum ſaliens, to invigorate the ſeminal plant: and thus we are at laſt conducted, by the regular analyſis of vegetable nature, to the firſt enlivening principle of their minuteſt origin.

GENERICAL NAMES, among philoſophers, the ſame with general terms. See the article GENERAL TERMS, ſupra.

GENESIS, among mathematicians, ſignifies the formation or production of ſome figure or quantity.

GENESIS, among divines, a canonical book of the Old Teſtament, and the firſt of the Pentateuch, or five books of Moſes. The Hebrews call it Bereſchith, or, In the beginning, theſe being the firſt words in the book. The Greeks gave it the name of Geneſis, from its beginning with the hiſtory of the creation of the world. It includes the hiſtory of two thouſand three hundred and ſixty-nine years, and beſides the hiſtory of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the riſe of religion; the general defection and corruption of the world; the deluge; the reſtoration of the world; the diviſion and peopling of the earth; and the hiſtory of the firſt patriarchs down to Joſeph, at whoſe death it ends.

It was eaſy for Moſes to be ſatisfied of the truth of what he delivers in this book, becauſe it came down to his time through a very few hands. For, from Adam to Noah, there was one man (Methuſelah) who lived to ſee them both: in like manner, from Noah to Abraham, Shem converſed with them both; Iſaac alſo did with Abraham and Joſeph, from whom theſe things might eaſily be conveyed to Moſes by Amram, who was cotemporary with Joſeph. Moſes is ſuppoſed to have written this book, during his retirement in the land of Midian, before he conducted the Iſraelites out of Egypt.

GENET, GENNET, or JENNET, in the manege, denotes a ſmall ſized, well proportioned Spaniſh horſe.

GENETHLIACUM, or GENETHLIAC POEM, verſes made on the birth of ſome prince, or other illuſtrious perſon, in which the poet, by a kind of prediction, promiſes him great advantages, great proſperity, and glorious victories.

GENEVA, a city near the confines of France and Switzerland, on the river Rhone, about ſixty miles north-weſt of Lyons: eaſt long. 6°; north lat. 46° 20'. Geneva is a fortified town, about two miles in circumference, ſituated at the weſt-end of a lake ſixty miles long, and twelve broad, called the lake of Geneva. It is a republic, governed by a council of 200, and a ſenate of twenty-five members; and is ſaid to contain 30,000 inhabitants.

GENEVA, or GIN, among diſtillers, an ordinary malt-ſpirit, diſtilled a ſecond time, with the addition of ſome juniper-berries. See the article JUNIPER.

Originally, the berries were added to the malt in the grinding; ſo that the ſpirit thus obtained was flavoured with the berries from firſt, and exceeded all that could be made by any other method. At preſent, they leave out the berries entirely, and give their ſpirits a flavour by diſtilling them with a proper quantity of oil of turpentine; which, though it nearly reſembles the juniper-berries, has none of their valuable virtues.

GENIAL, an epithet given by the pagans to certain gods who were ſuppoſed to preſide over generation.

GENICULI, among botaniſts, the knots or joints in the ſtalks of plants; whence they are denominated geniculate plants.

GENIOGLOSSI, in anatomy, two muſcles which lie immediately under the geniohyoideus. They ariſe fleſhy from the fore-part of the lower jaw internally, and inlarging themſelves, are inſerted in the root of the tongue. When theſe act, they pull the tongue forwards, and thruſt it out of the mouth.

GENIOHYOIDÆUS, in anatomy, is a muſcle which ariſes in the middle of the chin, above the mylohyoides, and near the ſynchondroſis of the jaw: its termination is in the baſe of the os hyoides. See the articles MYLOHYOIDES, SYNCHONDROSIS, &c.

GNIPA, in botany, a genus of plants, the flower of which conſiſts of a ſingle, rotated petal; its tube is very ſhort, and of a funnel-like ſhape; and the limb large, and divided into five deep ſegments. The fruit is a fleſhy berry, of an oval figure, ſmall at each end, truncated, and containing two cells, in which are a number of depreſſed angulated ſeeds.

GENIS, a town of Savoy, ſituated on the river Guier, twelve miles weſt of Chambery.

GENISTA, GREEN-WEED, or DYER'S-WEED, a genus of plants, with papilionaceous flowers; and the fruit a roundiſh, turgid, and unilocular pod, containing a ſingle kidney like ſeed.

GENITIVE, in grammar, the ſecond caſe of the declenſion of nouns. The regulation of one thing conſidered as belonging in ſome manner to another, has occaſioned a peculiar termination of nouns, called the genitive caſe: But in the vulgar tongues, they make uſe of a ſign to expreſs the relation of this caſe. In Engliſh they prefix the particle *of*, in French *de*, or *du*, &c. though in ſtrictneſs there are no caſes in either of theſe languages; inaſmuch as they do not expreſs the different relations of things by different terminations, but by additional prepoſitions, which is otherwiſe in the Latin, &c.

In the Hebrew tongue, the genitive caſe is marked in a very different manner from that of the Greek and Latin; for whereas in thoſe languages the noun governed is varied, in the Hebrew the noun governing undergoes the alteration.

GENIUS, a good or evil ſpirit, or dæmon, whom the ancients ſuppoſed ſet over each perſon, to direct his birth, accompany him in life, and be his guard.

Plato gives the following account of the genii.

They are ſpirits who never were engaged in matter, nor were ever joined to bodies. Of theſe genii Plato is of opinion that every man has his own, who watches over him, and is a witneſs not only of his actions, but of his very thoughts; and that, when the perſon dies, the genius conducts the ſoul of which he had the charge, to judgment, and aſſiſts at the trial: if the accuſed perſon falſifies, the genius convicts him; if he ſpeaks the truth, he confirms it; and it is upon his evidence that ſentence is pronounced.

GENIUS, in matters of literature, &c. a natural talent or diſpoſition to do one thing more than another; or the aptitude a man has received from nature to perform well and eaſily that which others can do but indifferently, and with a great deal of pains.

From the diverſity of genius, the difference of inclination ariſes in men, whom nature has had the precaution of leading to the employments for which ſhe deſigns them, with more or leſs impetuoſity in proportion to the greater or leſſer number of obſtacles they have to ſurmount, in order to render themſelves capable of anſwering this vocation. Thus the inclinations of men are ſo very different, becauſe they follow the ſame mover, that is, the impulſe of their genius. This, as with the painter, is what renders one poet pleaſing, even when he treſpaſſes againſt rules; while others are diſagreeable, notwithſtanding their ſtrict regularity.

The genius of theſe arts, according to the Abbé du Bos, conſiſts in a happy arrangement of the organs of the brain; in a juſt conformation of each of theſe organs; as alſo in the quality of the blood, which diſpoſes it to ferment, during exerciſe, ſo as to furniſh a plenty of ſpirits to the ſprings employed in the functions of the imagination. Here he ſuppoſes that the compoſer's blood is heated; for that painters and poets cannot invent in cool blood; nay, that it is evident they muſt be wrapt into a kind of enthuſiaſm when they produce their ideas. Ariſtotle mentions a poet who never wrote ſo well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures we have in Taſſo of Armida and Clorinda,

Clorinda, were drawn at the expence of a diſpoſition he had to real madneſs, into which he fell before he died. Do you imagine, ſays Cicero, that Pacuvius wrote in cold blood? No, it was impoſſible. He muſt have been inſpired with a kind of fury, to be able to write ſuch admirable verſes.

GENOA, a city and archbiſhop's ſee of Italy, and capital of the republic of the ſame name, is built on a ſtrand near the ſea, and riſes gradually to the top of a hill: the houſes, which are lofty and well built, riſing like the ſeats of a theatre, afford a fine proſpect at ſea. The harbour is large and deep, and the principal ſtreet, from one end to the other, reſembles a double row of palaces: eaſt long. 9° 30′, and north lat. 44° 30′.

This city, which is fortified by a double wall, is ſix miles round, and contains thirty pariſh churches, twenty colleges, and as many convents and religious houſes. The legiſlative authority is lodged in the great ſenate, conſiſting of the ſigniory and four hundred noblemen and principal citizens, elected annually out of the freemen. The ſigniory conſiſts of the doge and twelve other members, who hold their places two years. Four parts in five of the ſenate muſt agree to the enacting of laws. The doge is obliged to reſide in the palace the two years he is in office; and after they are expired, he retires to his own houſe, where his adminiſtration is either approved or condemned; and if the latter, he is proceeded againſt as a criminal.

The territories of the republic lie in the form of a creſcent, along the coaſt of the Mediterranean, extending 150 miles; but the country no where reaches above twenty miles from the ſea, and in ſome places not ten.

GENS D'ARMES. See GENDARMES.

GENTIAN, *Gentiana*, in botany, a genus of plants, the flower of which conſiſts of a ſingle petal, tubulated and imperforated at the baſe; and at the edge, divided into five ſegments, various in figure: the fruit is an oblong, cylindric, acuminated capſule, ſlightly bifid at the top, formed of two valves, and containing only one cell: the ſeeds are numerous and ſmall; the receptacles are two, and grow to the two valves of the capſule.

The root of this plant is large, remarkably tough, and of a firm texture. It is brought to us from Germany, where it is in many places cultivated as liquorice is amongſt us; and is to be choſen freſh, tough, of a middle ſize, free from the ſmall fibres, and well dried; though if it be ſcorched, it is to be rejected.

This root is one of the beſt ſtomachic bitters that the materia medica affords: it procures an appetite, and greatly aſſiſts digeſtion. But if we give credit to ſome authors, this is one of the leaſt of its virtues; they have recommended it as a febrifuge and an alexipharmic, and as the moſt certain remedy for the bite of a mad dog. On this occaſion it is not only recommended internally but externally, a cataplaſm made of venice-treacle and the powder of this root, being ordered to be applied to the wound. It is alſo ſaid to be a certain remedy for agues, and one of the beſt known medicines againſt the plague.

GENTILE, in matters of religion, a pagan, or worſhipper of falſe gods.

The origin of this word is deduced from the Jews, who called all thoſe who were not of their nation, by the name of גוים, gojim, i. e. gentes, which in the Greek tranſlations of the Old Teſtament, is rendered by τα εθνη; in which ſenſe it frequently occurs in the New Teſtament, as in Matt. vi. 32. *All theſe things the nations or gentiles ſeek.* Whence the Latin church alſo uſed *gentes*, in the ſame ſenſe as our gentiles, eſpecially in the New Teſtament. But the word *gentes* ſoon got another ſignification, and no longer meant all ſuch as were not Jews, but thoſe only who were neither Jews nor Chriſtians, but followed the ſuperſtitions of the Egyptians, Greeks, Romans, &c. In this ſenſe it continued among the Chriſtian writers, till their manner of ſpeech, together with their religion, was publicly and by authority received in the empire, when gentiles, from *gentes*, came into uſe: and then both words had two ſignifications, viz. in treatiſes or laws concerning religion, they ſignified pagans, neither Jews nor Chriſtians: and in civil affairs, they were uſed for all ſuch as were not Romans.

GENUS, among metaphyſicians and logicians, denotes a number of beings, which agree in certain general properties, common to them all: ſo that a genus is nothing elſe but an abſtract idea, expreſſed by ſome general name or term.

It is plain, therefore, that by a genus we do not barely ſignify one particular thing, nor yet a plurality of things; but a ſort or kind of things, all agreeing in certain general properties.

Thus animal is ſaid to be a genus in reſpect of man and brute, in regard man and brute agree in the common nature and character of animal: ſo a right lined figure of four ſides, is a genus in reſpect of a parallelogram, and a trapezium; and ſo likewiſe is ſubſtance, in reſpect of ſubſtance extended, which is body; and thinking ſubſtance, which is mind.

GENUS is alſo uſed for a character or manner applicable to every thing of a certain nature or condition: in which ſenſe it ſerves to make capital diviſions in divers ſciences, as muſic, rhetoric, anatomy, and natural hiſtory.

GENUS, in muſic, by the ancients called *genus melodiæ*, is a certain manner of dividing and ſub-dividing the principles of melody; that is, the conſonant and diſſonant intervals into their concinnous parts.

GENUS, in natural hiſtory, a ſub-diviſion of any claſs or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters.

The genera of animals ought to be eſtabliſhed upon the moſt natural, obvious, and diſtinctive characters. Thus it would be abſurd to range the ox and hog under the ſame genus, notwithſtanding they both have divided hoofs; and it would be equally ſo to make the roe deer, rain-deer, and elk, belong to different genera, merely becauſe the figure of their horns differs conſiderably. Hence the characters of the genera of animals are to be taken from the figure, ſituation, number, and proportions of their parts; which conſtitute ſuch a reſemblance, as eaſily diſtinguiſhes them from the ſpecies of any other genus.

In the claſs of quadrupeds, beſides a general reſemblance, the different genera are diſtinguiſhed from each other by the number and figure of their teeth, the ſhape of their feet, horns, and the like.

In the claſs of birds, the generical characters are drawn from the ſhape of their beak, and the number and diſpoſition of their toes.

In the claſs of amphibious animals, the generical characters are founded on the number of the cruſts or ſcales on the bellies and tails of the ſerpent-kind, and on the figure of the tail, and the number and ſhape of toes in the lizard, frog, and tortoiſe kinds.

As to the genera of fiſhes, they are founded on a certain agreement between a number of ſpecies, ariſing from the ſimilitude of their eſſential external parts; which always conſiſt in the ſituation of theſe parts, for the moſt part alſo in number, and frequently in their figure and proportion.

The inſect claſs are diſtinguiſhed into genera, from the number, figure, &c. of their antennæ, feet, ſnout, &c.

With reſpect to the vegetable kingdom, all plants and trees are reduced to genera from the conſideration of the number, ſituation, figure, and proportion of the parts of fructification.

In the ſame manner, the genera of foſſils are eſtabliſhed upon the figure, hardneſs, conſiſtence, inflammability, and other obvious properties of the ſubſtances that compoſe the mineral kingdom.

GEOCENTRIC, in aſtronomy, is applied to a planet or its orbit, to denote it concentric with the earth, or as having the earth for its center, or the ſame center with the earth. See the articles EARTH and PLANET.

GEOCENTRIC *Latitude of a Planet* is its diſtance from the ecliptic, as it is ſeen from the earth, which, even though the planet be in the ſame point of her orbit, is not

not conſtantly the ſame, but alters according to the poſition of the earth in reſpect to the planet. For let BAT *t* (plate LXIX. *fig.* 1.) be the orbit of the earth, PN *n* the orbit of the planet, which ſuppoſe to be at P; from which let fall on the plane of the ecliptic the perpendicular PE. In whatever part of her orbit the earth is, this line PE will always ſubtend the angle which meaſures the geocentric latitude of the planet. Suppoſe, therefore, the earth at T, and Venus in P, where ſhe comes neareſt to the earth, in which poſition Venus is ſeen in her inferior conjunction with the ſun, and her geocentric latitude is meaſured by the angle PTE. But if Venus ſhould be in the ſame ſituation, P, and the earth were at *t*, and from thence Venus were obſerved in her ſuperior conjunction with the ſun, where ſhe is at her greateſt diſtance from us, her geocentric latitude would be anſwerable to P*t* E, which is much leſs than the angle PTE, becauſe the diſtance P*t* is greater than PT.

What we have here ſaid of the latitude of Venus, is likewiſe true of that of Mercury, and upon the ſame account. See HELIOCENTRIC and LATITUDE.

GEOCENTRIC *Place of a Planet*, the place wherein it appears to us from the earth, ſuppoſing the eye there fixed: or it is a point in the ecliptic to which a planet ſeen from the earth is referred.

GEODÆSIA, the ſame with ſurveying. See the article SURVEYING.

GEOGRAPHICAL MILE, the ſame with the ſea-mile; being one minute, or the ſixtieth part of a degree of a great circle on the earth's ſurface. See the article DEGREE.

GEOGRAPHY, the doctrine or knowledge of the terreſtrial globe; or the ſcience that teaches and explains the properties of the earth, and the parts thereof which depend upon quantity.

Geography, as defined by Varenius, is that part of mixed mathematics, which explains the ſtate of the earth, and of its parts depending on quantity, viz. its figure, place, magnitude, and motion, with the celeſtial appearances, &c. In conſequence of this definition, that author divides geography into general and ſpecial, or univerſal and particular.

By univerſal geography, is underſtood that part of the ſcience which conſiders the whole earth in general, and explains its properties without regard to particular countries. This diviſion is diſtinguiſhed into three parts, abſolute, relative, and comparative. The abſolute part reſpects the body of the earth itſelf, its parts and peculiar properties, as its figure, magnitude, and motion; its lands, ſeas, and rivers, &c. The relative part accounts for the appearances and accidents that happen to it from celeſtial cauſes; and, laſtly, the comparative contains an explanation of thoſe properties which ariſe from comparing different parts of the earth together.

Special or particular geography is that diviſion of the ſcience which deſcribes the conſtitution and ſituation of each ſingle country by itſelf; and is two-fold, viz. chorographical, which deſcribes countries of a conſiderable extent; or topographical, which gives a view of ſome place, or ſmall tract of the earth.

Hence the object or ſubject of geography is the earth, eſpecially its ſuperficies and exterior parts.

The properties of geography, according to the ſame writer, are of three kinds, viz. celeſtial, terreſtrial, and human. The celeſtial properties are ſuch as affect us by reaſon of the apparent motion of the ſun and ſtars. Theſe are eight in number. 1. The elevation of the pole, or the diſtance of a place from the equator. 2. The obliquity of the diurnal motion of the ſtars above the horizon of the place. 3. The time of the longeſt and ſhorteſt day. 4. The climate and zone. 5. Heat, cold, and the ſeaſons of the year; with rain, ſnow, wind, and other meteors. 6. The riſing, appearance, and continuance of the ſtars above the horizon. 7. The ſtars that paſs through the zenith of a place. 8. The celerity of the motion with which, according to the Copernican hypotheſis, every place conſtantly revolves.

The terreſtrial properties are thoſe obſerved in the face of each country, and are ten in number. 1. The limits and bounds of each country. 2. Its figure. 3. Its magnitude. 4. Its mountains. 5. Its waters, viz. ſprings, rivers, lakes, and bays. 6. Its woods and deſarts. 7. The fruitfulneſs and barrenneſs of the country, with its various kinds of fruits. 8. The minerals and foſſils. 9. The living creatures there. 10. The longitude and latitude of the place.

The third kind of obſervations to be made in every country is called human, becauſe they chiefly regard the inhabitants of the place, and theſe are alſo ten in number. 1. Their ſtature, ſhape, colour, and the length of their lives; their origin, meat, and drink. 2. Their arts, and the profits which ariſe from them, with the merchandize and wares they barter one with another. 3. Their virtues and vices, learning, capacities, and ſchools. 4. Their ceremonies at births, marriages, and funerals. 5. The language which the inhabitants uſe. 6. Their political government. 7. Their religion and church government. 8. Their cities and famous places. 9. Their remarkable hiſtories. 10. Their famous men, artificers, and inventions of the natives.

Theſe are the three kinds of occurrences to be explained in ſpecial geography.

In univerſal geography, the abſolute diviſion of the earth, and the conſtitution of its parts, are examined; and the celeſtial phænomena in general are to be applied to their reſpective countries in ſpecial geography.

The principles of geography, or thoſe from which arguments are drawn for proving of propoſitions in that ſcience, are, according to Varenius, of three ſorts. 1. Geometrical, arithmetical, and trigonometrical propoſitions. 2. Aſtronomical precepts and theorems. 3. Experience, being that upon which the greateſt part of geography, and chiefly the ſpecial, is founded.

In proving geographical propoſitions, we are to obſerve that ſeveral properties, and chiefly the celeſtial, are confirmed by proper demonſtrations; but in ſpecial geography, excepting the celeſtial, almoſt every thing is explained without demonſtration; being either grounded on experience and obſervation, or on the teſtimony of out ſenſes: nor can they be proved by any other means. There are alſo ſeveral propoſitions proved, or rather expoſed to view, by the terreſtrial globe, or by geographical maps.

Other propoſitions cannot be ſo well proved, yet are received as apparent truths. Thus, though we ſuppoſe all places on the globe, and in maps, to be laid down in the ſame order as they are really on the earth; nevertheleſs, in theſe matters, we rather follow the deſcriptions that are given by geographical writers.

The manner in which we have treated the ſeveral geographical articles that occur throughout this work, may be ſeen under each head, and our diviſion of the ſcience may be ſeen in the introduction.

Geography is very ancient, at leaſt the ſpecial part thereof; for the ancients ſcarce went beyond the deſcription of countries. It was a conſtant cuſtom among the Romans, after they had conquered and ſubdued any province, to have a map or printed repreſentation thereof, carried in triumph, and expoſed to the view of the ſpectators. Hiſtorians relate, that the Roman ſenate, about an hundred years before Chriſt, ſent geographers into divers parts to make an accurate ſurvey and menſuration of the whole globe, but they ſcarce ever ſaw the twentieth part of it.

Before them, Necho, king of Egypt, ordered the Phœnicians to make a ſurvey of the whole coaſt of Africa, which they accompliſhed in three years. Darius procured the Ethiopic-ſea, and the mouth of the Indus, to be ſurveyed; and Pliny relates, that Alexander, in his expedition into Aſia, took two geographers to meaſure and deſcribe the roads; and that from their itineraries, the writers of the following ages took many particulars. Indeed this may be obſerved, that whereas moſt other arts and ſciences are ſufferers by war, geography and fortification alone have been improved thereby. Geography, however, muſt have been exceedingly defective, as a great part of the globe was then unknown, particularly all America, the northern parts of Europe and Aſia, with the Terra Auſtralis, and Magellanica; and as they were ignorant of the earth's being capable to be ſailed round, and of the torrid zone's being habitable, &c.

The honour of reducing geography to art and ſyſtem,

was reſerved for Ptolemy, who, by adding mathematical advantages to the hiſtorical method in which it had been treated of before, has deſcribed the world in a much more intelligible manner: he has delineated it under more certain rules, and by fixing the bounds of places from longitude and latitude, hath diſcovered others miſtakes, and has left us a method of diſcovering his own.

The principal writers upon geography, among the ancients, are Ptolemy, Pliny, and Strabo: among the moderns, Joannes de Sacroboſco, Cluverius, Heylin, Ricciolus, Weigelius, de Chales, and, above all, Varenius, with Jurin's additions; to which may be added Leibnecht, Sturmius, Morden, Gordon, Salmon, &c.

GEOMETRICAL, in general, an appellation given to whatever belongs to, or is ſtrictly connected with, geometry. See the article GEOMETRY.

GEOMETRICAL *Conſtruction of Equations.* See the article CONSTRUCTION.

GEOMETRICAL CURVE. See CURVE.

GEOMETRICAL LOCUS, or PLACE. See the article LOCUS.

GEOMETRICAL PACE. See PACE.

GEOMETRICAL PLANE, in perſpective. See the article PLANE.

GEOMETRICAL PROGRESSION and PROPORTION. See PROGRESSION and PROPORTION.

GEOMETRICAL *Solution of a Problem* is when it is ſolved according to the rules of geometry, and by ſuch lines as are truly geometrical, and agreeable to the nature of the problem.

GEOMETRY, γεωμετρια, originally ſignified no more than the art of meaſuring the earth, or any diſtances or dimenſions within it; but at preſent, it denotes the ſcience of magnitude in general; comprehending the doctrine and relations of whatever is ſuſceptible of augmentation or diminution, conſidered in that light.

Hence, to geometry may be referred the conſideration not only of lines, ſurfaces, and ſolids; but alſo of time, velocity, number, weight, &c.

Plato thought the word geometry an improper name for this ſcience, and accordingly ſubſtituted in its place the more extenſive one of menſuration; and, after him, others gave it the title of pantometry, as demonſtrating not only the quantities of all manner of magnitudes, but alſo their qualities, ratios, poſitions, transformations, relations, &c. And Proclus calls it the knowledge of magnitudes and figures, and their limitations; alſo of their motions, and affections of every kind.

Origin and Progreſs of GEOMETRY. This ſcience had its riſe among the Egyptians, who were in a manner compelled to invent it, to remedy the confuſion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their poſſeſſions. Thus this invention, which at firſt conſiſted only in meaſuring the lands, that every perſon might have what belonged to him, was called geometry, or the art of meaſuring land; and it is probable, that the draughts and ſchemes, which they were annually compelled to make, helped them to diſcover many excellent properties of theſe figures; which ſpeculations continued to be gradually improved, and are ſo to this day.

From Egypt geometry paſſed into Greece, where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The elements of geometry, written by this laſt in fifteen books, are a moſt convincing proof to what perfection this ſcience was carried among the ancients. However, it muſt be acknowledged, that it fell ſhort of modern geometry, the bounds of which, what by the invention of fluxions, and the diſcovery of the almoſt infinite orders of curves, are greatly enlarged.

Diviſion of GEOMETRY. This ſcience is uſually diſtinguiſhed into elementary, and higher or ſublime geometry.

The firſt, or elementary geometry, treats of the properties of right lines, and of the circle, together with the figures and ſolids formed by them. The doctrine of lines comes firſt, then that of ſurfaces, and laſtly that of ſolids.

The higher geometry comprehends the doctrine of the Conic ſections, and numerous orders of curves.

Geometry is again divided into ſpeculative and practical; the former treating of the properties of lines and figures, as Euclid's Elements, Apollonius's Conic Sections, &c. and the latter ſhewing how to apply theſe ſpeculations to the uſe of menſuration, navigation, ſurveying, taking heights and diſtances, gauging, gunnery, &c.

Uſefulneſs of GEOMETRY. The uſefulneſs of this ſcience extends to almoſt every art and ſcience. It is by the help of it that aſtronomers turn their obſervations to advantage, regulate the duration of times, ſeaſons, years, cycles, and epochas; and meaſure the diſtance, motions, and magnitudes of the heavenly bodies. It is by it that geographers determine the figure and magnitude of the whole earth; and delineate the extent and bearings of kingdoms, provinces, harbours, &c. It is from this ſcience too, that architects derive their juſt meaſures, in the conſtruction of public edifices as well as of private houſes.

It is by the aſſiſtance of geometry that engineers conduct all their works, take the ſituation and plans of towns, the diſtances of places, and the meaſure of ſuch things as are only acceſſible to the ſight. It is not only an introduction to fortification, but highly neceſſary to moſt mechanics, eſpecially carpenters, joiners, mathematical-inſtrument-makers, and all who profeſs deſigning.

On geometry likewiſe depends the theory of muſic, optics, perſpective, drawing, mechanics, hydraulics, pneumatics, &c.

GEORGE, or *Knights of St.* GEORGE, has been the denomination of ſeveral military orders, whereof that of the garter is one of the moſt illuſtrious. See the article GARTER.

Croſs of St. GEORGE, a red one in a field argent, which makes part of the Britiſh ſtandard. See CROSS and GARTER.

GEORGIAN MONKS and NUNS, religious of Georgia, in Aſia, who follow the rule of St. Baſil. See the article BASIL.

GEORGIC, a poetical compoſition upon the ſubject of huſbandry, containing rules therein, put into a pleaſing dreſs, and ſet off with all the beauties and embelliſhments of poetry.

The ſtyle proper to a georgic muſt be worked up with a great deal of thought and vigour, that the words may be lively, and every thing the poet deſcribes may immediately riſe up to the reader's view. Heſiod and Virgil are the two greateſt maſters in this kind of poetry. In Virgil's Georgics are contained the moſt uſeful rules for huſbandry in all its branches. Virgil has infinitely exceeded Heſiod in this ſort of writing: he began his Georgics at the perſuaſion of Mæcenas, and was near ſeven years about them: they are, with reſpect to the diction, the moſt finiſhed of all his works, and even of all the poems that ever were compoſed in Latin. The moderns have produced nothing in this kind, except Rapin's book of Gardening; the celebrated poem entitled Cyder, by Mr. Philips, who, if he had enjoyed the advantage of Virgil's language, would have been ſecond to Virgil in a much nearer degree; and the Hop-Garden, by Mr. C. Smart.

GERANITES, in natural hiſtory, an appellation given to ſuch of the ſemipellucid gems, as are marked with a ſpot reſembling a crane's eye.

GERANIUM, crane's bill, in botany, a genus of plants, the flower of which conſiſts of five large, patent, oval, and vertically cordated petals; the fruit is a capſule, of the form of a crane's bill.

Geranium ſtands recommended by authors, as one of the greateſt vulneraries and aſtringents of the vegetable world, particularly for ſtopping hæmorrhages, exceſs of the menſes, &c.

GERM, among gardeners, the ſame with bud. See the article BUD.

GERMAN, in genealogy, denotes entire or whole: thus, a brother-german is one both by the father's and mother's ſide; and couſins-german are the children of brothers or ſiſters.

GERMAN,

GERMAN, or GERMANIC, alſo denotes any thing belonging to Germany; as the German empire, German flute, &c.

GERMANDER, in botany, the Engliſh name of the teucrium of Linnæus. See the article TEUCRIUM.

Water-GERMANDER, a plant called by botaniſts ſcordium. See SCORDIUM.

GERMANY, an extenſive empire of Europe, ſituated between 5° and 19° eaſt longitude, and between 45° and 55° north latitude; bounded by Denmark and the Baltic ſea on the north, by Poland and Hungary on the eaſt, by Switzerland and the Alps on the ſouth, and by France, Holland, &c. on the weſt.

It is divided into ten circles, three of which lie on the north, viz. Upper and Lower Saxony, and Weſtphalia; three on the ſouth, viz. Auſtria, Bavaria, and Swabia; three about the middle, viz. Franconia, and the Upper and Lower Rhine; the tenth, which conſiſted of the duchy of Burgundy and the ſeventeen provinces of the Netherlands, have long been detached from the empire.

There are in Germany upwards of three hundred ſovereign princes and ſtates, moſt of them arbitrary in their reſpective territories.

GERMEN, or GERM, the ſame with bud. See the article BUD.

GERMINATION, the firſt ſprouting of the ſeeds of plants. See VEGETATION.

GERVES's *Engine*, a curious engine for raiſing water to ſupply a gentleman's ſeat, &c.

If there be a ſpring affording but a ſmall quantity of water, and having but a ſmall fall, ſuppoſe 10 feet, it is poſſible by the loſs of ſome of the water to raiſe the reſt to ſupply a gentleman's ſeat, or any place where it is wanted; but in a leſs quantity than what runs waſte, if the place to which the water is to be raiſed be higher than the fall of the ſpring. For example, the fall of one hogſhead 10 feet will raiſe very near a hogſhead 10 feet: one hogſhead, falling 10 feet, will raiſe very near ¼ of a hogſhead 40 feet. This has been thought of by Schottus a great many years ago, and he gave a draught of it; but it was never put in execution (at leaſt to any good purpoſe) till the late George Gerves, carpenter, erected an engine for this purpoſe, for Sir John Cheſter, Bart. at his ſeat at Chicheſter, in Buckinghamſhire.

Explanation of Plate LXIX. *fig.* 2. repreſenting Gerves's engine.

A. Is a ſmall ſpring of water, running four gallons per minute, conveyed 72 yards into B.

B. A ciſtern holding about 12 gallons, with a fall from B to C.

C. A ciſtern 10 feet below B, where the waſte is conveyed off along D.

D. A drain, or ſewer.

E. A plan of the building by a ſcale of 8 feet in an inch.

FG. A ſection of the houſe built over the well or ciſtern, drawn by a ſcale of 4 feet in an inch; with

HIK. Three floors for the conveniency of fixing and ordering the engine; on the uppermoſt is

LMN. A frame of timber, on which the moving part is ſupported (part broken off in the figure, to ſhew the work;) acroſs this frame lies

O. An horizontal axis, three feet and an half long, moving on two gudgeons in braſſes. Upon this axis are framed three wheels.

(1) P. A wheel 2 feet diameter ſhrouded, whoſe ſole is 5 inches broad, and ſhod with iron.

(2) Q. The largeſt wheel 6 feet diameter, lying cloſe by the other, 1 inch and an half broad on the ſole, and ſhrouded; this is ſpiraled 2 inches, both in ſole and ſhrouds.

(3) R. A wheel 3 feet 10 inches diameter, fixed on the ſides of the ſpokes of the wheel Q, and ſhrouded; this is ſpiraled ¼ of an inch.

P. Upon the wheel P is fixed a chain, made flat and very flexible, which, after it has wrapped once round, is made double to ſtride on each ſide the ſingle part, to prevent its fretting and galling, and to keep exactly the perpendicular.

SS. To this chain is hung SS, a long rod of iron, at the bottom of which the greater bucket *d* is fixed.

Q. Upon the wheel Q is fixed a ſmaller chain made flat as the other; and, when this wheel has made one revolution from left to right, the ſpiral ſole takes up as much of the chain as is between T and T 2. The lower part of the chain from T 2 to T 3 has croſs bars, which fall upon the edge of the ſhroud in notches plated with iron; which, by the help of the ſpiral, not only prevent this part of the chain from riding upon the other, but help to equiponderate the increaſe of weight of the other chain SS.

R. Upon the wheel R is faſtened a rope, one end of which goes about V.

V. A wheel of 2 feet diameter, to which that end is fixed; and on the ſame axis is fixed W.

W. Another wheel one foot diameter, to which is faſtened a rope, which goes over a pulley to a ſliding weight in a box at X.

X. Being the ſtilyard end of Y *a a*.

Y *a a*. A quadrant wheel moving on the axis Y; the rope falling upon pullies, running betwixt iron plates, upon the circumference.

Z. Is a lead weight, fixed to counter-balance the weight of the chains, keeping exactly an equilibrium in every poſition they move in.

O. Upon one end of the axis O is a ſtrong iron wheel, giving motion to a fly *b*, which regulates the motion of the engine.

TT. Upon one end of the chain TT is a copper bucket *c*, whoſe capacity is about 5 gallons, having a valve in the bottom on the left hand, and a waſte pipe near the top on the right: upon the lower end of the rod SS, is hung *d*.

d. A copper bucket containing about 15 gallons; in the bottom of this is a valve opened by a trigger falling upon a ſtud at the bottom of the well.

i i. Are iron-rods for the guiding of the buckets, whoſe ears have braſs rolls in them, and incloſe three ſides of each rod, which is ſquare.

The operation.

When the leſſer bucket deſcends, it falls upon a trigger at 4, which is jointed to a treddle at 5, expreſſed with pointed lines, moving on an axis at 6, which by a rod at 7 opens a valve in the bottom of the ciſtern B; whence the water, by a braſs cock and branch-pipe, is conveyed underneath into both buckets, *c* and *d*.

When the leſſer bucket has received about four gallons and an half, it runs out at the pipe or ſpout into a leaden trough, which conveys the water underneath the ciſtern into the great bucket, till it overpoiſes the leſſer; which deſcending, and raiſing the leſſer bucket, the valve ſhuts, and the water that is left in the trough and branch-pipe runs into the greater bucket *d*, accelerating the motion, which falling 10 feet, the leſſer bucket riſes 30 feet; which taking up the trough *f*, and its trigger ſtriking upon a ſtud at *e*, its valve is opened, and its water runs out into a ſmall ciſtern at *f*, and down a pipe *g g*, and ſo is conveyed to the place deſigned: at the ſame time a ſtud opens the valve of the greater bucket, the water running along D, the drain or ſewer.

When both buckets are empty, the leſſer overpoiſes the greater, and deſcends down to the ciſtern, bringing up the greater, where they fill as before.

To regulate the weight of the chains in every poſition, as they act in winding on and off the wheels P and Q, the ſpiraling of the wheels helps in ſome meaſure; but the quadrant wheel and ſtilyard X, with the weight Z, compleat the equilibrium, by acting with the greateſt force in the horizontal poſition, when the chain T is all down, and acts with its whole weight upon the wheel Q: then, as that chain is drawn up, its acting weight being thereby diminiſhed, the ſtilyard X is moving down towards its perpendicular, where the weight Z ceaſes to influence the motion of the wheel R; at which time the ſliding weight runs down to keep the rope tight.

At the firſt moving down of the leſſer bucket, the weight X ſlides up to a ſhoulder, before any motion is given to the ſtilyard; but, whilſt the chain T evolves from its wheel Q, its acting weight increaſing; and, at the ſame time, the chain S wrapping itſelf upon the wheel P, its acting weight decreaſing; the ſtilyard, by riſing higher, brings the line of direction of the weight Z

farther from the center of the quadrant, and ſo lays a greater force or obſtruction to retard the wheel R, and continually keeps a counter-balance.

The fly *b* regulates the motion of the engine to an equal velocity; and, by its running forwards, after the buckets are quite up or down, holds them ſteady till they begin to fill or empty, and prevents their recoiling back.

This engine, at a ſlow motion, carries up one bucket full in five minutes; but, if the ſpring run double the quantity, it would go up twice in the ſame time; and an engine, in this kind, may be made to raiſe one hogſhead per minute, or more, if required; the waſte water not being the hundredth part of what is ſpent by a water-wheel, to raiſe an equal quantity of water to the ſame height.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the ſingular number, through all the caſes except the vocative; as, nom. *amandum*, gen. *amandi*, dat. *amando*, accuſ. *amandum*, abl. *amando*.

Grammarians are very much embarraſſed to ſettle the proper nature and character of gerunds. It is certain they are no verbs, nor diſtinct moods of verbs, in regard they do not mark any judgment or affirmation of the mind, which is the eſſence of a verb; beſides their having caſes, which verbs have not. Some, therefore, will have them to be adjectives paſſive, whoſe ſubſtantive is the infinitive of the verb: on this footing they are denominated verbal nouns, or nouns formed of verbs, and retaining the ordinary regimen thereof. See the article NOUN.

The gerunds are derived from active, neuter, and deponent verbs; and, for the moſt part, they follow their ſignification; as, *docendum*, from *doceo*; *currendo*, from *curro*; *loquendum*, from *loquor*.

GESTATION, among phyſicians, the ſame with pregnancy. See the article PREGNANCY.

GESTURE, in rhetoric, conſiſts chiefly in the proper action of the hands and face. It is a kind of natural language, that ſupplies the uſe of ſpeech in perſons born dumb. See the article ACTION.

GEUM, *Avens*, in botany, a genus of plants, the corolla of which conſiſts of five roundiſh petals, with narrow ungues of the length of the cup, and inſerted into it; there is no pericarpium; the common receptacle of the ſeeds is oblong, hairy, and placed on the cup, which is, at that time, reflex: the ſeeds are numerous, compreſſed, hiſpid, and each furniſhed with a long geniculated ſtyle.

GIAGH, in chronology, a cycle of twelve years; in uſe among the Turks and Cathayans.

Each year of the giagh bears the name of ſome animal: the firſt, that of a mouſe; the ſecond, that of a bullock; the third, of a lynx or leopard; the fourth, of a horſe; the fifth, of a crocodile; the ſixth, of a ſerpent; the ſeventh, of a horſe; the eighth, of a ſheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They alſo divide the day into twelve parts, which they call giaghs, and diſtinguiſh them by the name of ſome animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIBBOUS, in aſtronomy, a term uſed in reference to the enlightened parts of the moon, whilſt ſhe is moving from the firſt quarter to the full, and from the full to the laſt quarter: for all that time the dark part appears horned, or falcated; and the light one hunched out, convex, or gibbous. See the article MOON.

GIFT, in law, a conveyance, by which either lands or goods are paſſed: it is of larger extent than a grant, being applied to things moveable and immoveable.

GIGG, or JIGG, in muſic, denotes a briſk and lively air; or an airy kind of dance, to a ſprightly meaſure.

GILBERTINES, a religious order founded in England by St. Gilbert, in the reign of Henry I. The nuns followed the rule of St. Benedict, and the monks that of St. Auguſtin. There were many monaſteries of this order in different parts of England.

GILDING, the art of ſpreading or covering a thing with gold, either in leaf or liquid. See the article GOLD.

We have this advantage over the ancients, in the manner of uſing and applying the gold, that the ſecret of painting in oil, lately diſcovered, furniſhes us with means of gilding works, capable of enduring all the violences of time and weather, which theirs could not.

There are ſeveral methods of gilding in uſe among us, as gilding in water, gilding in oil, gilding by fire, &c.

The Method of Water-GILDING. — Water-gilding requires more preparation than oil-gilding, and is chiefly on wooden works, and thoſe made of ſtucco; and theſe too muſt be ſheltered from the weather. A ſize is uſed for this way of gilding made of ſhreds, &c. of parchment or gloves boiled in water to the conſiſtence of a jelly. If the thing to be gilt be of wood, it is firſt waſhed with this ſize, boiling hot, and then ſet to dry; and afterwards with white paint mixed up with the ſame ſize. Some uſe Spaniſh white for this purpoſe, and others plaſter of Paris, well beaten and ſifted. This ſized paint muſt be laid on with a ſtiff bruſh; which is to be repeated ſeldomer or oftener according to the nature of the work, as ten or twelve times in flat or ſmooth works, but ſeven or eight will be ſufficient in pieces of ſculpture. In the former caſe they are applied by drawing the bruſh over the work, in the latter by dabbing it. When the whole is dry, they moiſten it with fair water, and rub it over with ſeveral pieces of coarſe linnen, if it be on the flat; if not, they beat or ſwitch it with ſeveral ſlips of the ſame linnen, tied to a little ſtick, to make it follow and enter all the cavities and depreſſures thereof.

Having thus finiſhed the white, the next thing to be done is to colour it with yellow ochre; but if it be a piece of ſculpture in relievo, they firſt touch it up, and repair the ſeveral parts, which may have happened to have been disfigured by the ſmall iron inſtruments, as gouges, chiſſels, &c. The ochre uſed for this purpoſe muſt be well ground and ſifted, and mixed up with the ſize beforementioned. This colour is to be laid on hot; and in works of ſculpture, ſupplies the place of gold, which ſometimes cannot be carried into all the depreſſures and cavities of the foliages and other ornaments. A lay is alſo applied over this yellow, which ſerves for the ground on which the gold is to be laid: this lay is uſually compoſed of Armenian bole, blood-ſtone, black lead, and a little fat; to which ſome add ſoap, and oil of olives; others, burnt-bread, biſtre, antimony, glaſs of tin, butter, and ſugar-candy. Theſe ingredients being all ground down together with hot ſize, three lays of this compoſition is applied upon the yellow, the one after the other has been dried; being cautious not to put any into the cavity of the work to hide the yellow.

The bruſh, uſed for this purpoſe, muſt be a ſoft one; and when the matter is become very dry, they go over it again with a ſtronger bruſh, to rub it down, and take off the ſmall grains that ſtick out, in order to facilitate the burniſhing of the gold.

To be prepared for gilding, you muſt have three ſorts of pencils; one to wet, another to touch up and amend, and a third to flatten; alſo a gilding cuſhion, for ſpreading the leaves of gold on when taken out of the book; a knife to cut them, and a ſquirrel's tail fitted with a handle; or elſe a piece of fine ſoft ſtuff on a ſtick, to take them up directly and apply them. You are firſt to begin with wetting your pencils; by which the laſt lay laid on with water is moiſtened, that it may the better receive and retain the gold. Then you are to lay the leaves of gold on the cuſhion, and if whole, you muſt take them up with the ſquirrel's tail, but if in pieces, with the other inſtrument, or the knife wherewith they are cut, and lay and ſpread them gently on the parts of the work you had moiſtened before. If the leaves, as they frequently do, happen to crack or break in laying on, theſe breaches muſt be made up with ſmall bits of leaf, taken up upon the repairing pencil, and the whole work is to be ſmoothed either with the ſame pencil, or another ſomething larger; the gold being preſſed into the dents, into which it could not be ſo eaſily carried by the ſquirrel's tail.

The work having been thus far gilded, muſt be ſet to dry, in order to be burniſhed or flatted. See the article BURNISHING.

The laſt operation is the applying the vermeil in all the little lines and cavities; and to ſtop and amend any little faults

PLATE LXX.

1st Compartment.

2d Compartment.

3d Compartment.

faults with ſhell-gold. The compoſition called vermeil is made of gum guttæ, vermilion, and a little of ſome ruddy-brown, ground together with Venetian varniſh and oil of turpentine. Some gilders, inſtead of this, make ſhift with fine lacca, or dragon's blood, with gum-water.

Sometimes inſtead of burniſhing the gold, they burniſh the ground or compoſition laid on the laſt before it, and only afterwards waſh the part over with the ſize. This method is chiefly practiſed for the hands, face, and other nudities in relievo; which, by this means, do not appear ſo very brilliant as the parts burniſhed, tho' much more ſo than the parts perfectly flat.

To gild a piece of work, and yet preſerve white grounds, they apply a lay of Spaniſh white, mixed with a weak fiſh-glue, on all the parts of the ground, whereon the yellow or the laſt lay might run.

See plate LXX. firſt compartment.

Fig. 1. A woman laying on the ſize.

Fig. 2. A workman applying the vermeil.

Fig. 3. A workman ſmoothing and preſſing the gold into the dents.

Fig. 4. A workman repairing the defects.

Fig. 5. A workman laying on the ſized paint.

Fig. 6. A workman grinding the colours.

The Method of GILDING *in Oil.* — This operation requires much leſs apparatus than that before-mentioned. The baſis or matter whereon the gold is laid, in this method, is the remains of colours found ſettled to the bottom of the pots in which painters waſh their pencils. This matter, which is very viſcid or ſticky, is firſt ground, and then paſſed through a linen-cloth, and thus laid on the matter to be gilt, after it is waſhed once or twice over with ſize; and if it be wood, with ſome white paint.

When this is almoſt dry, but yet is ſtill unctuous enough to catch and retain the gold, the leaf-gold is laid on, either whole, if the work be large, or cut to pieces, if ſmaller: the leaves of gold are taken up and laid on with a piece of fine, ſoft, well-carded cotton; or ſometimes by a palat for the purpoſe, or ſometimes with the knife with which the leaves were cut, according to the parts of the work that are to be gilded, or the breadth of the gold that is to be laid on. As the gold is laid on, they paſs over it a coarſe ſtiff pencil or bruſh, to make it ſtick and as it were incorporate with the ground; and after this they mend any cracks that may have happened in it, either with the ſame pencil or one that is ſmaller, as has been ſhewn before in water-gilding.

This kind of gilding is chiefly uſed for domes and roofs of churches, courts, banquetting-houſes, &c. and for figures of plaſter of Paris, lead, &c.

The Method of GILDING *with liquid Gold.* — This is performed by gold reduced to a calx and amalgamated with mercury, in the proportion of about an ounce of mercury to a dram of gold. To perform this, they heat a crucible red-hot, and then put the gold and mercury into it, ſtirring them gently about till the gold be found melted and incorporated into a maſs with the mercury. When this is done, they caſt them into water, to waſh and purify them; and out of that into other waters, where the amalgama, which is almoſt as liquid as if there were nothing but quick-ſilver in it, may be preſerved a long time for uſe.

Before they proceed to lay this amalgamated gold on the metal, they firſt render the metal rough, by waſhing it over with aqua-fortis, or aqua-ſecunda; and afterwards rinſe the metal in fair water, and ſcour it a little with fine ſand, and then it is ready for the gold.

They next cover over the metal with the mixture of gold and mercury, taking it up with a ſlip of copper, or a bruſh made of braſs-wire, ſpreading it as even as poſſible, to do which they wet the bruſh from time to time in fair water. Then they ſet the metal to the fire, upon a grate, or in a ſort of cage, under which ſtands a pan of coals; and in proportion as the mercury, evaporating and flying off, diſcovers the places where gold is wanting, they take care to ſupply them by adding new parcels of amalgama.

Then the work is rubbed over with the wire-bruſh, dipped in beer or vinegar, which leaves it in a condition to be brought to a colour, which is the laſt part of the proceſs, and which the gilders keep to themſelves as a mighty ſecret.

The Method of GILDING *by Fire on Metal.* — To prepare the metal, they ſcratch it well, or rake it; then poliſh it with a poliſher, and afterwards ſet it to the fire to blue, i. e. to heat till it appear of a blue colour. When this has been done, they clap on the firſt lay of leaf-gold, rubbing it lightly down with a poliſher; and expoſe it thus to a gentle fire. They uſually give it but three ſuch lays, or four at the moſt, each lay conſiſting of a ſingle leaf for common works, and of two for extraordinary ones: after each lay, it is ſet a-freſh to the fire; and after the laſt lay, the gold is in condition to be burniſhed.

See plate LXX. ſecond compartment.

Fig. 3. A ſtone and muller for grinding colours.

Fig. 4. A workman poliſhing the metal.

Fig. 5. A workman laying on the gold.

Fig. 6. A workman laying on the lacquer on an emboſſed piece of metal.

Fig. 7. A workman laying on the vermeil.

Fig. 8. A workman burniſhing the gilded metal.

To gild Paper. — Grind bole-armoniac with rain-water, and give one laying of it; when it is dry, take glair of eggs, and add to it a little ſugar-candy and gum-water, which lay over the former, and upon this, when it is dry enough, lay leaf-ſilver, or leaf-gold.

To gild the Leaves of Books. — Take bole-armoniac, eight penny-weight; ſugar-candy, two penny-weight: mix and grind them with glair of eggs: then on a bound book (while it is in the preſs, after it hath been ſmeared with glair of eggs, and is dried) ſmear the ſaid compoſition, let it dry, then rub it well and poliſh it; then with fair water wet the edges of the book, and ſuddenly lay on the gold, preſs it down gently with cotton, let it dry, and then poliſh it with a tooth.

GILDING *on Leather.* This operation is performed in the ſame manner as that of gilding paper. But when the leather is intended to be decorated with flowers, or other devices, the figures are either drawn or printed on the leather, with the common ſize, and the deſigns covered with leaf gold; and after the ſuperfluous gold is bruſhed off, it is burniſhed.

See plate LXX. third compartment.

Fig. 2. A workman covering the deſigns with leaves of gold or ſilver.

Fig. 3. A workman ſmoothing the leather with a burniſher.

Fig. 4. A workman paring a belt of leather on a ſtone previous to its being gilt.

Fig. 5. The rolling-preſs for printing the deſigns.

GILL, a meaſure of capacity, containing a quarter of a pint.

GILL is alſo a name for ground-ivy, which, being infuſed in ale, makes what is known by the name of gill-ale; a ſort of medicated ale, ſaid to be abſterſive and vulnerary.

GIN, or GENEVA, among diſtillers. See the article GENEVA.

GIN, in mechanics, a machine for raiſing great weights, fitted with a windlaſs and winches at each end, where eight or nine men heave, and round which a rope is reeved, that goes over a pulley at the top; and the whole ſupported by three feet, forming a triangle.

GINGER, *zinziber*, in botany. See the article ZINZIBER.

GINGER-BREAD, a richer kind of bread, the flavour and taſte whereof are heightened and improved with ſpices, and particularly with ginger, whence the name.

The preparation of ginger-bread is as follows: grate two-penny white loaves into two pounds of almonds well blanched and pounded; then add two ounces of ginger, finely ſcraped, liquorice, and aniſe in powder, of each half an ounce; add to theſe five or ſix ſpoonfuls of roſemary-water; and knead all into a paſte, with a pound of ſugar; mould it, and roll it thin, then print it, and dry it in a ſtove.

Others make it of treacle, citron, lemon, and orange-peel, with candied ginger, coriander and carraway-

ſeeds, mixed up with as much flour as will make it into a paſte.

GINGER-WINE is made as follows: take three gallons of water, an ounce of race-ginger, and three pounds of ſugar; boil them for an hour, and then put into it three lemons, and a little good yeaſt; cloſe up the veſſel, and let it ſtand five days: if it has ſo worked as to be clear in that time, it may be bottled; if not, let it ſtand longer, until it has worked ſufficiently; and in ten days after it may be drank.

GINGIVÆ, the gums, in anatomy, a hard ſort of fleſh, inveſting the alveoli, or ſockets of the teeth.

The gums conſiſt of the common membrane of the mouth, and the perioſteum of the jaws, to which they adhere very cloſely and firmly. They are furniſhed with a vaſt number of blood-veſſels, whence their florid red colour; and they ſerve for the covering of the jaws, and the keeping the teeth faſt in their ſockets.

GINGLYMUS, γιγλυμος, one of the three ſubdiviſions of that kind of articulation called diarthroſis. See the articles ARTICULATION and DIARTHROSIS.

The ginglymus is that juncture of the bones wherein they mutually receive and are received by one another, as is the caſe of the articulation of the humerus and cubitus. See HUMERUS, &c.

The ginglymus is again ſubdivided chiefly into three kinds; the firſt is when the ſame bone at the ſame extremity receives, and is reciprocally received by another bone, after the manner of an hinge, as that of the cubitus and humerus: the ſecond is when a bone receives another at one of its extremes, and is received into another, as the vertebræ do: the third is that where a bone is received into another after the manner of a wheel, or the axis of the wheel in a box; ſuch is that of the ſecond vertebra of the neck in the firſt.

GINSENG, in botany, a famous plant greatly eſteemed in China.

The root of the ginſeng is of an oblong figure, never growing to any great ſize, being generally about four or five inches long, and its thickneſs that of one's little finger. It is of a firm texture, its ſurface is furrowed and wrinkled in different places. It is of a browniſh colour on the outſide, and ſomewhat yellowiſh within; and is ſo pure and fine, that it ſeems tranſparent. The top of the root, when it is ſent entire to us, is found compoſed of knots, or tubera, placed over one another in an irregular manner: theſe are formed of the bottoms of the decayed ſtalks of the ſeveral preceding years. When the root is fair and entire, it is eaſy to know by theſe how old it is; but very old roots not being ſo much in repute, the people who gather ginſeng have often the precaution to cut off ſome, or even all thoſe knobs, before they dry the root.

Ginſeng is of a very agreeable and aromatic ſmell, tho' not very ſtrong; its taſte is acrid and aromatic, and has ſomewhat bitter in it. It is to be choſen ſound and firm, moderately heavy, not too tough, and of a good ſmell. Before it be bought, it will be prudent to cut every root through, for the Chineſe, of whom we have it, frequently find a way to introduce pieces of lead into it, to increaſe the weight.

The roots of the ginſeng and ninzin are ſo much alike in their ſhape, colour, and virtues, that they are frequently miſtaken for one another, and by the generality of authors underſtood to be the ſame, notwithſtanding that they belong to two very different plants, and are of two different genera.

The Chineſe and Tartars collect the root of this plant with infinite pains, at two ſeaſons of the year, ſpring and autumn. They are forbid to touch them with any iron-inſtrument, ſo that they can only clean them with wooden knives. They waſh them in a decoction of millet-ſeed, and afterwards hang them over the fumes of the ſame liquor, which they boil in conſiderable quantities for that purpoſe, in a cloſe veſſel, in the upper part of which the root is ſuſpended, over the ſurface of the liquor: after this they dry it for uſe, thus it becomes tranſparent. The ſmall fibres which are taken off, they boil in water, and make an extract of them, which they uſe in the ſame intention with the root.

The Chineſe value the ginſeng ſo highly, that it ſells with them for three times its weight in ſilver. They, as well as the Aſiatics in general, think the ginſeng almoſt an univerſal medicine: they have recourſe to it in all diſeaſes, as the laſt remedy, and readily give themſelves over when it will not cure them; but the virtues moſt generally aſcribed to it, are thoſe of a reſtorative, a provocative, and a cordial. It is famous in the eaſt for giving ſtrength to thoſe who have diſabled themſelves by the too free uſe of women: there they alſo recommend it greatly in the ſmall-pox, fevers of all kinds, diſorders of the ſtomach and bowels, and tell us that diarrhœas and dyſenteries are cured by it: but they caution people not to give it in too large doſes to perſons of a florid ſanguine conſtitution, on whatever occaſion it may be neceſſary to them. The European phyſicians eſteem it a good medicine in convulſions, vertigoes, and all nervous complaints, and recommend it as one of the beſt reſtoratives known.

Its doſe is from ten grains to twenty, in powder; and from one dram to two to the pint, in infuſions.

GIRANDOLE, a kind of branched candle-ſtick.

GIRDERS, in architecture, ſome of the largeſt pieces of timber in a floor.

Their ends are uſually faſtened into ſummers and breaſt-ſummers, and joiſts are framed in at one end to the girders.

The ſize of girders and ſummers, upon the rebuilding of London, were ordained by act of parliament, to be in length from ten to twenty-ſix feet, in breadth from eleven to ſeventeen inches, and in depth from eight to fourteen inches. It was alſo ordained by the ſame ſtatute, that no girder or ſummer ſhould be leſs than ten inches in the wall, and that their ends ſhould be laid in loam; as alſo that they be of good hearty oak, as free from knots as may be, becauſe that will be the leaſt ſubject to breaking, and may with more ſafety be relied on in this croſs and tranſverſe work.

Chriſtians of the GIRDLE, the Chriſtians of Aſia, particularly thoſe of Syria and Meſopotamia, who to this day wear a large leathern girdle, being enjoined thereto by Motavakkel, tenth caliph of the family of the Abaſſides, in the year 856, as a badge of their profeſſion.

Order of the GIRDLE. See CORDELIER.

GIRDLE, in architecture. See CINCTURE.

GIRKIN, a term uſed by gardeners for a ſmall kind of cucumber.

GIRONNE, or GIRONNY, in heraldry, a coat of arms divided into girons, or triangular figures, meeting in the center of the ſhield, and alternately colour and metal.

GIRT, in the menſuration of timber, denotes the circumference of a tree. See the article TIMBER.

GIRT, in the ſea language, the ſituation of a ſhip riding at anchor with two cables, which are drawn ſo extremely tight by mechanical powers, as to prevent the ſhip from turning or veering round on the change of the wind or tide, one of the cables bearing ſtrongly againſt her keel: in this poſition ſhe muſt ride with her broadſide or ſtern to the wind and tide, till one or both of the cables are ſlackened ſo as to ſink under the keel, that the ſhip may not be retarded in her motion.

GISON, or GEISON, in Jewiſh antiquity, ſignifies, according to Joſephus, a little wall, about breaſt high, made round the temple of Jeruſalem, and round the altar of burnt-ſacrifices, to keep the people at a diſtance. This author, in his books of Antiquities, makes the giſon three cubits high, and but one in his hiſtory of the Jewiſh war.

GIVEN, among mathematicians and philoſophers, the ſame with data. See the article DATA.

GLACIS, in building, an eaſy, inſenſible ſlope, or declivity.

The deſcent of the glacis is leſs ſteep than that of the talus. In gardening, a deſcent ſometimes begins in talus, and ends in glacis. See the article TALUS.

The glacis of the corniche is an eaſy imperceptible ſlope in the cymatium, to promote the deſcent and draining off the rain-water.

GLACIS, in fortification, that maſs of earth which ſerves as a parapet to the covered way, ſloping eaſily towards the champaign, or field.

The

The glacis, otherwiſe called eſplanade, is about ſix feet high, and loſes itſelf by an inſenſible diminution in the ſpace of ten fathoms. See ESPLANADE.

GLADE, in gardening and agriculture, an opening and light paſſage made through a wood, by lopping off the branches of trees along that way.

GLADIATORS, in antiquity, perſons who fought generally in the arena at Rome, for the entertainment of the people.

GLAMA, a ſpecies of Peruvian camel, with the back even, and the breaſt gibboſe.

GLAND, in anatomy, a ſmall body, formed by the interweaving of veſſels of every kind, covered with a membrane, uſually provided with an excretory duct, and deſtined to ſeparate ſome particular fluid from the maſs of blood, or to perfect the lymph. See BLOOD and LYMPH.

Many of the anatomical writers of the very firſt claſs, and among theſe ſome who have written profeſſedly of the glands, and have made it their peculiar buſineſs to examine nicely into their nature, and explain their ſtructure, have yet, from mere difficulty of aſcertaining adequate ideas of the term, evaded giving a definition or general deſcription of the glands; and in conſequence of this, numberleſs errors, and an almoſt inextricable confuſion, has crept into the ſtudy of this important part of the human ſtructure.

Other authors, who have had more boldneſs, if not greater abilities than thoſe who have avoided meddling with definitions of theſe parts, have ventured to eſtabliſh what they call glands: but theſe differ ſo much from one another in what they would eſtabliſh as general certainty, and have produced ſuch imperfect and erroneous definitions, that they have all either included parts which themſelves own not to be glands in the definition, or they have limited the term to ſome particular ones, and excluded what themſelves and every body elſe allow to be glands out of the number.

Glands are parts of a peculiar ſtructure; they are of various figures, colours, and conſiſtencies, as they are deſtined to different offices. The ancients ſuppoſed them formed of a different kind of fleſh from that of the reſt of the body; but the parts to which they have given the name of glands, though they are as different from one another as poſſible in figure, ſize, and colour, yet they are eaſily known, and diſtinguiſhed as glands by all the world; notwithſtandiug the difficulty of giving a definition or even a general character of a gland, which ſhall include all the true glands, and take in no other parts of the body with them.

Many writers on this ſubject have aſſerted, that wherever there is a ſecretion of any kind performed, there is a gland; but this is not true, for there are many ſecretions performed in the body, and thoſe even of the largeſt and moſt important kind, where there are no glands to perform them: the chyle is ſecreted in the inteſtines without the aſſiſtance of glands; the ſemen is ſecreted in the teſticles; and the pituita in the pituitary ſinuſes of the brain, where there are no glands at all. On the other hand alſo it is to be obſerved, that there are glands received and allowed by all writers as ſuch, which do not appear to perform any ſecretions at all; and the ancients themſelves agreed in giving the name of glands to ſeveral parts, though they were not aſſured that they ſecreted any thing, nor even in ſome caſes believed that they did. But Mery, in ſeveral papers in the Memoirs of the Paris Academy, not only proves that all the ſecretions are not performed by means of glands, but that many of the ſecretions of moſt importance to the body are performed without glands. We are to add alſo, that every beginner in anatomy, at this time, knows a gland to be ſuch when he ſees it, without knowing any thing of its uſe. There are therefore other characters by which a gland may be known, though by its office and uſe it cannot.

Other writers, of the number of whom is the great Malphigi, in diſſections of particular bodies, having found veſicles in the brain, liver, kidneys, and other parts of the body, thence declared them to be glandulous in their ſtructure: but in theſe caſes, the bodies diſſected were all morbid ones; and as the ſame veſicles are not found in healthful ones, nor indeed any thing analogous to them, it is a ſufficient proof that they are not natural parts of their ſtructure; and beſides, veſicles and glands are different. See VESICLE and VASCULOUS.

It is evident that the ancients called certain parts of the human body glands, and that for no other reaſon but becauſe they found them compoſed of a peculiar kind of fleſhy ſubſtance, of a peculiar habit, or external appearance, without paying any the leaſt regard either to their internal ſtructure, their ſpherical figure, (by which character ſome define them) or their uſe.

If it be aſked, ſays Heiſter, what this particular habit in the glands is? or how we are to know it? the anſwer is, that the peculiar complication and arrangement of the veſſels, from which there ariſes a form obviouſly diſtinguiſhable at ſight from the muſcles, the fat, the bones, the membranes, the veſſels, and in fine from every other part of the human fabric, gives a ſufficiently certain, determinate, and ſtriking notice of it.

The differences of the glands among themſelves, as eſtabliſhed by many authors, are very numerous: it will not be neceſſary to run into the whole diſquiſition; we ſhall only ſelect a few which are more generally eſtabliſhed than the reſt, and of more immediate and real uſe. We ſhall firſt divide them into two general kinds, the ſimple, called alſo conglobate glands, and the conglomerate. See the articles CONGLOBATE and CONGLOMERATE.

The glands differ alſo greatly in regard to their conſiſtence: ſome of them are conſiderably hard and firm, and others extremely ſoft and tender: of the latter kind in particular are the glands ſituated in the articulations of the bones of the ſeveral parts of the body.

They differ alſo very conſiderably in colour. Some of them are of a pale, whitiſh, red, or fleſhy colour; others of a ſtrong, deep red; others yellowiſh, or browniſh, and ſome evidently blackiſh.

Their differences in figure are as conſiderable alſo as thoſe in colour: ſome of them are round, others oval, others oblong, and many others of figures as different as well can be from any one of theſe regular ones: the pancreas, the thyroide, and the thymus, are inſtances of this; ſome of them have obtained their names from their peculiar figure: of this number are the glandula pinealis, the miliares, and others. See the articles PANCREAS, THYROIDE, THYMUS, &c.

The Uſes of the GLANDS are alſo as different as their colours or figures: ſome of them are ſalival, mucoſe, and lymphatic; others are mucilaginous, ſebaceous, and waxy; others lachrymal, pituitary, &c. and from theſe their ſeveral contents or ſecretions, they are termed lachrymal, &c. See the articles SALIVAL, LYMPHATIC, MUCILAGINOUS, &c.

The Situation of the GLANDS is another article in which they differ, and from which many of them have their ſeveral names; ſuch are the parotides, maxillares, linguales, thyroide, palatine, labial, jugular, cervical, axillary, inguinal, lumbary, inteſtinal, meſenteric, renal, &c. See the articles PAROTIDE, MAXILLARY, LINGUAL, &c.

And, finally, the ſize of the glands is a thing in which they differ moſt obviouſly and eſſentially.

Of the GLANDS *in particular*. The particular glands of the body, or ſuch as are truly and properly of this denomination, are, according to Heiſter, as follow; and firſt of the glands of the head.

In the ſinuſes of the dura mater, and out of them, at the ſides, there are found a number of ſmall glands deſcribed by Pacchonius; and there are ſometimes others viſible in the foveæ of the os frontis, and about the diviſions of the veſſels, between the dura mater and the arachnoides. Theſe glands ſeem deſtined for the ſecreting of a fluid to moiſten the dura mater. Other glands of the brain are the pineal gland, and the pituitary gland. See the articles PINEAL, PITUITARY, DURA MATER, and BRAIN.

In the exterior part of the head, that is, out of the cavity of the ſkull, we have the parotids, and maxillary glands, the ſublinguals, the linguals, the labials, the palatine, and the buccinals, which are diſtributed here and there about the membrane of the mouth; and are each deſcribed in their places. In the orbit alſo there is the lachrymal glands; under the eyes are the ſebaceous or

ſeraceous

ſeraceous glands, the tonſils in the fauces, the mucoſe glands in the pituitary membrane of the noſtrils, and the ceruminoſe glands of the ears, each of which are deſcribed under their ſeveral heads. See the articles EYE and EAR.

The principal gland of the neck is the thyroides, beſides which there are alſo found in the neck a great number of leſſer ones, diſtributed here and there among the muſcles and fat. Their figure, their number, and their ſituations, vary in different ſubjects; but in general thoſe in the anterior part of the neck are called jugulars; and thoſe in the hinder part, occipitales and cervicales. The uſe of theſe is hitherto uncertain; it is generally ſuppoſed that they are of ſervice to the lymphatic veſſels, but what ſort of uſe they can be of to them, does not ſo eaſily appear. See the articles THYROIDES, JUGULARES, OCCIPITALES, CERVICALES, and NECK.

Ruyſch and Morgagni have alſo deſcribed and figured glands in the epiglottis: and Morgagni has deſcribed others in the other parts of the larynx, particularly about the arytænoide cartilages, as alſo in the trachea: but theſe are often ſo ſmall, that they are ſcarce diſcoverable in diſſection.

The œſophagus, eſpecially towards its upper part, has a great number of glands; and it is common to find a little aperture or oſculum in the center of each, which has much the appearance of an excretory duct.

In the thorax we meet with the gland thymus; as alſo with the glandulæ bronchiales: theſe laſt are very obſervable glands, ſituated externally in the larger diviſions of the trachea and bronchia. They are of a blackiſh colour; and their uſe, like that of many others of the glands of this part of the body, is yet very little known. It had been long ſuppoſed that they ſerved to ſecrete a liquid which they diſcharged into the bronchia, for the lubricating and moiſtening theſe parts; but Vercellonius will have it, that they ſecrete a fluid whoſe uſe is to be aſſiſtant in the digeſtion of our food, and that they diſcharge it into the œſophagus through certain extremely minute ducts. See the articles THORAX, THYMUS, BRONCHIA, &c.

About the fifth vertebra of the back, there is ſometimes found in the thorax a remarkable gland adhering to the poſterior part of the œſophagus: this is uſually called glandula dorſalis. It is, in different ſubjects, of various ſizes. It is often of the ſize of a kidney-bean; ſometimes of that of an almond, and ſometimes conſiderably larger; in others, it is much leſs than the ſmaller, and ſometimes it is wholly wanting; or at leaſt ſo extremely minute and inconſiderable, that the beſt diſſectors are not able to find it. Sometimes alſo two glands are found in this part in the place of one. Vercellonius is of opinion, that this gland is alſo placed there for the ſecretion of a fluid ſerving to aſſiſt the digeſtion of our food in the ſtomach: but Fantonus, and ſome others, ſuppoſe, that theſe glands diſcharge a fluid of a mucous nature into the cavity of the œſophagus: ſeveral authors affirm, that in dogs theſe glands are found tumid, and inhabited by a number of oblong and ſlender red worms. See DORSUM, VERTEBRA, and OESOPHAGUS.

In the abdomen there are very conſiderable numbers of glands: the largeſt of them is the pancreas; after this in ſize come the glandulæ renales, or capſulæ atrabiliariæ; after theſe the meſeriacs, and the inteſtinals of Brunner and Peyer in the inteſtines. See ABDOMEN, &c.

The glands of the ſtomach are very eaſily diſtinguiſhable in dogs and hogs; but in human ſubjects, it is difficult to find them: many anatomiſts have doubted them. Morgagni, however, diſcovered them ſo fairly in human ſubjects, that there is no doubt left about them.

About the vertebra of the loins, near where the receptaculum chyli is ſituated, and about the os ſacrum, and the diviſions of the iliac veſſels, are many glands of various ſizes and figures: they are commonly called lumbares, ſacræ, and iliacæ, and they have numerous lymphatics entering into them, and diſcharging their contents into the receptaculum chyli. The lumber glands have been ſometimes found ſwelled to the bigneſs of a man's fiſt.

In the concave part of the liver, about the ingreſs of the vena portæ and the neck of the gall-bladder; as alſo about the ſpleen, near the ingreſs of the veſſels, there are frequently found conglobate glands, of about the bigneſs of kidney-beans: theſe are called by authors hepatic glands, cyſtic glands, and by other names formed from the names of the parts they are near; and they ſeem to ſerve the lymphatic veſſels. See the article LIVER.

About the left orifice of the ſtomach, there ſometimes alſo is found, according to Vercellonius, a gland which he ſays is equal to a kidney-bean in ſize; he alſo ſays that it has ducts opening into the cavity of the ſtomach. In hogs this gland is very conſpicuous, but in human ſubjects it is not ſo.

Many authors have told us, that in the omentum, in every part where the fat lies, there are a number of glands whoſe office it is to ſecrete it. Diſſection ſhews us a few about that part where it is joined to the pylorus; and as to the reſt, it is not neceſſary that there ſhould be glands, becauſe there is fat: for that may be, and is, indeed, in great abundance ſecreted immediately from the arteries.

In the gall-bladders of oxen there are often found a number of ſmall glands of a yellow colour, not unlike the ceruminous glands in the auditory paſſage.

In human ſubjects the ſame kind of glands are alſo ſometimes found. The bladder and the ureters have alſo ſometimes a number of ſmall glands, but they are very indeterminate in number and ſize, and are not always indeed found in the ſame place, eſpecially about the ureters. Thoſe about the bladder are uſually ſituated towards the neck of it, and are ſometimes tolerably conſpicuous.

In the parts of generation of man there occur, 1. The glandulæ Cowperi. 2. The glandulæ Littri. And, 3. The odoriferous glands of Tyſon. See PENIS. As to the latter ones, thoſe of them which are ſituated in the interior part of the prepuce, are much more obvious than thoſe about the coronæ penis, where it is very difficult to diſtinguiſh them from the nervous papillæ of the ſame part. 4. We meet with the proſtatæ. 5. The glands of the veſiculæ ſeminales; but theſe are rarely ſeen diſtinct. Terraneus alſo deſcribes ſix ſmall glands in the urethra virilis. See the articles PREPUCE, PROSTATÆ, VESICULÆ SEMINALES, and URETHRA.

In the parts of generation in women, we are to refer to the number of the glands, 1. Thoſe which Morgagni diſcovered in the nymphæ: theſe have a very near alliance with the glandulæ odoriferæ of the penis in men. 2. Authors tell us of the glands in the female as well as the male urethra: but the diſſector will find only little foramina and ducts in the place of them. 3. About the extremity of the urethra, however, in the vagina, there are ſometimes found evident glands, ſituated beneath them: theſe, as well as the glands of the nymphæ, are often very turgid in the time of parturition. 4. The veſicles ſometimes met with near the internal orifice of the uterus, and taken by ſome for a new ovary, are not properly glands, though ſome people have been very poſitive that they were ſuch; having nothing of the habit and peculiar appearance of glands, and being in truth only veſicles. 5. Some have alſo maintained that there are glands in the uterus, by which the menſtrual diſcharges are ſecreted; but this notion ariſes only from the falſe hypotheſis, that where there are no glands, there can be no ſecretion. See the articles VAGINA and UTERUS.

Among the glands which belong to the articulations, and the extremities, we are to mention, firſt, the axillary ones. 2. The inguinal glands; theſe laſt, being ſituated on each ſide in the groin near the crural veſſels, are in various diſeaſes apt to grow tumid, and inflamed. Abſceſſes are often formed in them; but their uſe in the body is not eaſily underſtood. 3. The glands, called from their diſcoverer glandulæ Harveianæ, in the articulations: they are alſo called from the matter they ſecrete glandulæ mucoſæ. Theſe are the ſofteſt of all the glands in the body; they ſecrete a mucous ſoft fluid, which ſerves to lubricate the joints, and render their motions eaſy, and to prevent their growing dry, and cohering together.

About the ſcapula, the flexure of the elbow, the hand, the knee, and the foot, there are alſo found here and

there ſome ſmall glands; as alſo in ſome places between and among the muſcles: but as their number and ſituation, as well as their ſize and figure, are very uncertain and variable, it is not neceſſary to recount them here.

We are, however, yet to ſpeak of the cutaneous glands. Verheyen tells us, that Steno had diſcovered, that there is a gland ſituated under every diſtinct pore of the ſkin, from whence there ariſes a veſſel for the conveyance of the matter of ſweat, which terminates at the ſurface of the cutis: and hence Verheyen, though he does not ſay that he had ever ſeen any of theſe glands himſelf, ventures to give them a place among the parts he deſcribes; and calls them ſubcutaneous glands. The pores of the ſkin are ſo extremely numerous, that if, according to theſe authors, there were a gland belonging to every one of them, the glands muſt be almoſt infinite in number. But in diſſection, when the cutis has been carefully cleared from the fat that is under it, it is certain no ſuch glands are ſeen, either in the ſeparated fat, or on the lower ſurface of the cutis: there are indeed always found little portions of the fat here and there inſinuating themſelves into the little foveolæ, or holes in the cutis; but pieces of fat will be diſtinguiſhed from glands with very little difficulty by an expert anatomiſt. From this, and from innumerable ſearches after theſe glands, it appears, that there are indeed no ſuch glands as thoſe called ſubcutaneous. See the article CUTIS.

GLANDERS, in the manege, a diſeaſe in horſes, conſiſting of a thick, ſlimy, corrupt humour, running from the noſtrils, of a different colour, according to the different degrees of malignity, or as the infection has been of a ſhorter or longer continuance; being white, yellow, green, black, or bloody.

Authors aſcribe this diſeaſe to various cauſes: ſome to infection; others, to a diſorder of the lungs; others, to the ſpleen; ſome to the liver; and others, to the brain. After it has been of ſo long a ſtanding, as that the matter is become of a blackiſh colour, which is uſually in its laſt ſtage, they ſuppoſe it to come from the ſpine; and hence they call it the mourning of the chine.

Kernels and knots are uſually found under the caul in this diſorder; and as theſe grow bigger and more inflamed, ſo the glanders increaſe more.

For the cure of the glanders Mortimer gives the following receipt.

Take a pint of children's chamber lye; two ounces of oil of turpentine; half a pint of white vinegar; four ounces of flower of brimſtone; half a handful of rice; boil this compoſition till it comes to a pint, and give it to the horſe faſting; and let him faſt after it ſix hours from meat, and twelve from water.

GLANDULAR, or GLANDULOUS, among anatomiſts, ſomething abounding with, or partaking of the nature of, glands.

GLANDULE, or GLANDULA, a term uſed by anatomiſts to expreſs a ſmall gland. See GLAND.

GLANS, in anatomy, the anterior extremity of the penis, called by other different names, as the head of the penis, the nut of the penis, and the balanus of the penis. See the article PENIS.

GLANS is alſo uſed to denote the tip or extremity of the clitoris, from its reſemblance both in form and uſe to that of the penis. The principal difference conſiſts in this, that it is not perforated as is the glans of the penis.

GLASS, a kind of factitious, brittle, and tranſparent body, produced by the action of fire upon a fixed ſalt and ſand that readily melts.

When, or by whom, the art of making glaſs was invented is uncertain. Some will have it to have been known before the flood, but without any proof. However, glaſs could not be unknown to the ancients; for a kiln of bricks can hardly be burnt, or a batch of pottery ware made, but ſome of the bricks and ware will be at leaſt ſuperficially turned into glaſs.

Pliny tells us that the diſcovery was owing to the following accident: Some merchants being driven by ſtreſs of weather to the mouth of the river Belus in Syria, were obliged to make a fire on the ground to dreſs their victuals; and there being a great quantity of the plant kali on the ſpot, ſome of the aſhes of this plant were accidentally mixed with the ſand of the place, which produced a vitrification. This hint the Sidonians improved, and brought it into uſe.

Venice, for many years, excelled all Europe in the fineneſs of its glaſſes; but lately the French and Engliſh have excelled the Venetians; ſo that we are no longer ſupplied from abroad.

The manufactured glaſs at preſent in uſe may be divided into three general kinds, white tranſparent glaſs, coloured glaſs, and common green or bottle glaſs. Of the firſt kind, there is a great variety of ſorts, according to the ſeveral purpoſes intended to be ſerved by it, either for making domeſtic utenſils, or lights for incloſed places: and of the ſecond, there is likewiſe a ſtill greater multiplicity of ſpecies, differing in their colour, or other properties, according to the occaſions for which they are wanted: but of the laſt, there is no diſtinguiſhed difference of ſort, except what the accidental manner of preparation and management, practiſed according to the ſkill or art of particular directors of manufactories may occaſion.

From the nature of vitrification, it appears, that all fixed bodies are capable of being the materials of perfect glaſs under ſome circumſtances; but as the means of vitrification are limited with regard to the manufactured glaſs, ſuch bodies only are proper to become the ingredients of the perfect kinds of it, as are eaſily to be procured in due quantity, and admit of being vitrified by the heat of a furnace either alone, or by their commixture with others, which may promote this change in them: and in the caſe of the imperfect ſorts, bodies that are not capable of being vitrified by the means there employed, are alſo taken in as materials, where they are required to give the particular properties wanted in each peculiar ſort. The principal ſubſtances, therefore, that are choſen for the compoſition of manufactured glaſs, are, ſand flints, and other foſſile bodies of a ſtony and earthy texture; metals and ſemi-metals of all kinds previouſly prepared by calcination, or other operations; arſenic and zaffer, which are prepared parts of a foſſile; and all ſalts of a fixed kind.

Among theſe ſubſtances there are ſome, which are ſtrongly reluctant to the vitreous fuſion, and could ſcarcely alone be ever converted to glaſs; at leaſt not by the heat of any furnaces; and yet are ſuch as are moſt capable of giving firmneſs and tenacity to that in which they are admitted; as alſo of being more copiouſly provided at a ſmall expence. There are others, on the contrary, that vitrify in a much leſs heat than that commonly employed in the working of glaſs; and have likewiſe this attendant properly along with their own proneneſs to vitreous fuſion, that they accelerate and produce it in many of thoſe that are otherwiſe more repugnant to it; and cauſe them, by their commixture, to vitrify in a greatly leſs degree of heat than they otherwiſe would.

This property of promoting vitrification is called technically fluxing the bodies on which they ſo act; and on the proper application of this principle to practice lies the main ſtreſs of ſkill in the art of compounding glaſs; as the ſavings in the original coſt of the ingredients, in time and in fuel, as well as the qualities of glaſs produced, depend chiefly on the thorough intelligence in this view of the nature of the bodies proper to become ingredients of it. The next important relation, in which bodies ſtand with reſpect to the compoſition of glaſs, is the effect they may have on its colour by their admixture: in order to deſtroy all kinds of which in ſome caſes, and to produce them in others, ingredients are frequently added, that are not otherwiſe neceſſary; as being no way ſubſervient to the general view. This conſtitutes therefore the other great object of ſkill in the art of making glaſs: for the knowing properly how to take away all colour from the tranſparent white glaſs, and to impart any kind deſired to proper compoſitions on other occaſions, is of the next great moment to the being able, by the moſt cheap and eaſy means, to procure a due vitrification.

According to the above ſpecified intentions, in which

the ſeveral ſubſtances ſerving for the materials of glaſs are uſed, they may be properly diſtinguiſhed into three kinds, as making the body, flux, and colorific matter.

The ſubſtances which have been employed in forming the body of glaſs are ſand, by which is only to be underſtood the white kinds, flints, talc, ſpar, and ſeveral other ſtony foſſils. All theſe vitrify of themſelves too ſlowly to produce perfect glaſs by the degree of heat that can be applied to them when in large maſſes; which makes them therefore require the addition of thoſe other kinds, whoſe fluxing power may remedy this defect in them; while they on the other hand, being of low price, and to be procured in unlimited quantities, and giving that hardneſs, ſtrength, and inſolubility, which cannot be had in any glaſs formed of other ſubſtances without them, are yet eſſential and indiſpenſibly neceſſary ingredients in all kinds of manufactured glaſs.

The ſubſtances which are uſed as fluxing ingredients in glaſs, are red lead, pearl-aſhes, nitre, ſea ſalt, borax, arſenic, and wood-aſhes containing the calcined earth and lixiviate ſalts as produced by incineration. The preſence of ſome of theſe bodies is always equally neceſſary with that of thoſe which form the body in all the compoſitions of manufactured glaſs. But the uſe of them both, with reſpect to choice and proportion, is greatly varied in different works; even where the ſame kind of glaſs is intended to be produced; as the general nature of them has never been hitherto underſtood by the directors of ſuch works; and they have only implicitly followed the beſt receipts they could procure, carefully keeping them a ſecret, when they happened either by communication or their accidental diſcovery to be poſſeſſed of ſuch improvement, as gave them any advantages over their fellow operators.

The ſubſtances which have been applied as colorific matter in manufactured glaſs, are extremely numerous and various; as all the ſpecies of metals and ſemi-metals, with many other mineral and foſſile bodies, have been uſed for the producing ſome colour or other; and make a large field of ſpeculative and practical knowledge. The art of ſtaining glaſs, with all the variety of colours in the greateſt degree of force and brightneſs, is not however of ſo much importance commercially conſidered, as the knowing how to baniſh and exclude, with eaſe and certainty, the colours which of themſelves ariſe in moſt of the compoſitions for glaſs intended to be perfectly tranſparent and colourleſs: for this laſt purpoſe, nitre and magneſia are the principal ſubſtances employed in the manufactories of this country; and extremely well anſwer the end, tho' not without enhancing the expence of the glaſs by the uſe of the firſt; and in a ſmall degree injuring its tranſparency by that of the latter; as may be demonſtrated by principles that are unqueſtionable in themſelves, though wholly unknown to thoſe who are practically concerned in theſe matters.

From theſe three kind of ſubſtances duly combined together by commixture and adequate heat, or in ſome caſes from the two firſt only, all the ſorts of manufactured glaſs at preſent in uſe are formed. The general manner of doing which is to reduce thoſe kinds of bodies that are in groſſer maſſes, to powder; and then, all the ingredients being thoroughly well mixed together by grinding, and put into proper pots, to place them in a furnace where the heat is ſufficient to bring them to a due ſtate of fuſion, in which they are to be continued till the vitrification be completed.

This proper degree of vitrification muſt be diſtinguiſhed by the tranſparent and equal appearance of the matter when a ſmall portion is taken out and ſuffered to cool: except in the caſe of thoſe ſorts where the glaſs is not perfect, with regard to which, a judgment muſt be made from their having attained or wanting that peculiar appearance, which the particular ſort is required to have. It may be proper to ſubjoin, that in all caſes, the vitrification is ſooner and more eaſily made perfect in proportion as the ingredients are reduced to the ſtate of a finer powder, and more intimately commixed.

We have obſerved, that the materials formerly employed to give a body to glaſs are, ſand, flints, talc, ſpar, and ſome other ſtony foſſils; but ſand is, at preſent, the almoſt only kind of ſubſtance which is uſed in this intention in the Britiſh manufactures of glaſs.

The kind of ſand moſt fit for making the white tranſparent kinds of glaſs, is that brought from Lynn in Norfolk, by the name of which place it is diſtinguiſhed: and there is alſo another kind of this, but inferior, brought from Maidſtone in Kent. It is white and ſhining; and, examined by means of a microſcope, appears to be ſmall fragments of rock cryſtal; from which it does not ſeem, by any experiments, to differ in its qualities, and the glaſs formed of it may therefore properly be conſidered as made of cryſtal.

The materials being all prepared and duly mixed, the matter muſt be put into the pots and urged to fuſion, by a heat proportioned to the ſtrength of the flux in the compoſition, and this muſt be continued till the whole maſs become one uniform fluid; and have acquired the qualities neceſſary in that particular kind of glaſs which is intended to be produced. There is an attention to another object, however, required in the mean time, which is, the taking off the ſcum and foulneſs that will ariſe on the glaſs in the action of the ingredients on each other, and the coction of the matter. This is to be done by means of proper ladles; and ſhould be effectually performed before the glaſs be worked; otherwiſe it will be ſo fouled by this ſubſtance, as to be rendered of very little value. This matter is called ſandover; and is ſold to the colourmen, who diſpoſe of it to the potters; and they uſe it in the compoſitions of their glazings.

The exact time for keeping the ſeveral compoſitions of glaſs in fuſion, in order to their perfect vitrification, can by no means be ſettled by rule: for there is ſo much variation in the diſpoſition of different parcels of materials of the ſame kind to vitrify; and likewiſe ſo great an uncertainty with reſpect to the degrees of heat maintainable even in the ſame furnace, that it muſt be left to the judgment of the operator. But where the power of the flux is weaker, as may be gathered from the nature and proportions of the ingredients in the compoſition, or where the heat is leſs intenſe, a greater time will neceſſarily be required, than in the caſe of ſtronger fluxes, and briſker fires. No damage can, however, accrue from allowing a longer fuſion than may be neceſſary to give the glaſs the appearance of being perfect, except the loſs of time and conſumption of fuel: for with reſpect to the white tranſparent glaſs, it is always improved in its hardneſs, and clearneſs, by a larger coction.

In order to examine whether the glaſs have attained to its due ſtate of vitrification, an iron rod, of which the end ſhould be bright, or at leaſt entirely free from ruſt, muſt be dipped in the melted matter: and what adheres to it ſhould be firſt tried, with reſpect to its ductility or readineſs to ſuffer itſelf to be drawn out in long threads; and if this quality be found in it to a ſufficient degree, being ſuffered to cool, it ſhould be carefully inſpected, to form a judgment of its colour and clearneſs. If it be tranſparent, colourleſs, and free from all ſpecks and bubbles, it may be concluded perfect, and fit to be wrought: but if it want theſe marks, more time muſt be given, according to the degree of defectiveneſs: and, after a reaſonable allowance of ſuch time, it muſt be examined again by the ſame means; and if not yet perfect, a further time muſt be given, and then the ſame trial made again.

Working or blowing of Window or Table GLASS. See the article BLOWING *of Glaſs*.

*Caſting or running of large Looking-*GLASS *Plates.* — The furnace G (plate LXXI. *fig.* 1.) is of a very large dimenſion, environed with ſeveral ovens, or annealing furnaces, called carquaſſes, beſides others for making of frit, and calcining old pieces of glaſs. This furnace, before it is fit to run glaſs, coſts three thouſand five hundred pounds. It ſeldom laſts above three years, and even in that time it muſt be refitted every ſix months. It takes ſix months to rebuild it; and three months to refit it. The melting pots are as big as large hogſheads, and contain about 2000 weight of metal. If one of them burſts in the furnace, the loſs of the matter and time amounts to 250 l. The heat of this furnace is ſo intenſe, that a bar of iron laid at the mouth thereof becomes red hot in leſs

leſs than half a minute. The materials in theſe pots are the ſame as deſcribed before; and A is the man breaking the frit for that purpoſe. When the furnace is red hot, theſe materials are put in at three different times, becauſe that helps the fuſion; and in twenty-four hours they are vitrified, refined, ſettled, and fit for caſting. H is the bocca, or mouth of the furnace, K is the ciſtern that conveys the liquid glaſs it receives out of the melting-pots in the furnace to the caſting table. Theſe ciſterns are filled in the furnace, and remain therein ſix hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pully marked I, and placed L, by two men P, P. This carriage has no middle piece; ſo that when it has brought the ciſtern to the caſting table M, they ſlip off the bottom of the ciſtern, and out ruſhes a torrent of flaming matter O, upon the table: this matter is confined to certain dimenſions by the iron rules N, N, N, which are moveable, retain the fluid matter, and determine the width of the glaſs; while a man R, with the roller Q reſting on the edge of the iron rulers, reduceth it as it cools to an equal thickneſs, which is done in the ſpace of a minute. This table is ſupported on a wooden frame, with truſtles for the convenience of moving to the annealing furnace; into which, ſtrewed with ſand, the new plate is ſhoved, where it will harden in about ten days. After this the glaſs needs only be ground, poliſhed, and foliated for uſe.

Grinding and poliſhing of Plate GLASS. Glaſs is made tranſparent by fire, but it receives its luſtre by the ſkill and labour of the grinder and poliſher, the former of whom takes it rough out of the hands of the maker.

In order to grind plate-glaſs, they lay it horizontally upon a flat ſtone table (*fig.* 2.) made of a very fine grained free-ſtone; and for its greater ſecurity they plaſter it down with lime, or ſtucco; for otherwiſe the force of the workmen, or the motion of the wheel, with which they grind it, would move it about.

This ſtone-table is ſupported by a ſtrong frame, A, made of wood, with a ledge quite round its edges, riſing about two inches higher than the glaſs. Upon this glaſs to be ground is laid another rough glaſs not above half ſo big, and ſo looſe as to ſlide upon it; but cemented to a wooden plank, to guard it from the injury it muſt otherwiſe receive from the ſcraping of the wheel, to which this plank is faſtened; and from the weights laid upon it, to promote the grinding or friture of the glaſſes. The whole is covered with a wheel, B, made of hard light wood, about ſix inches in diameter; by pulling off which backwards and forwards alternately, and ſometimes turning it round, the workmen who always ſtand oppoſite to each other, produce a conſtant attrition between the two glaſſes, and bring them to what degree of ſmoothneſs they pleaſe, by firſt pouring in water and coarſe ſand; after that a finer ſort of ſand as the work advanceth, till at laſt they muſt pour in the powder of ſmalt. As the upper or incumbent glaſs poliſhes, and grows ſmoother, it muſt be taken away, and another from time to time put in its place.

This engine is called a mill by the artiſts, and is uſed only in the largeſt ſize glaſſes; for in the grinding of the leſſer glaſſes, they are content to work without a wheel, and to have only four wooden handles faſtened to the four corners of the ſtone, which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glaſs to an exact plainneſs, it is turned over to the care of the poliſher, who with the fine powder of Tripoli-ſtone, or emery, brings it to a perfect evenneſs and luſtre. The inſtrument made uſe of in this branch, is a board, *c*, *c*, furniſhed with a felt, and a ſmall roller, which the workman moves by means of a double handle at both ends. The artiſt in working this roller aſſiſted with a wooden hoop, or ſpring, to the end of which it is fixed; for the ſpring, by conſtantly bringing the roller back to the ſame points, facilitates the action of the workman's arm.

*Burroughs's Machine for grinding and poliſhing Plate-*GLASS. See the article BURROUGHS's *Machine*.

Grinding and poliſhing of Optic GLASSES. See GRINDING and POLISHING.

Painting in GLASS. The ancient manner of painting in glaſs was very ſimple, and conſequently very eaſy; it conſiſted in the mere arrangement of pieces of glaſs of different colours in ſome ſort of ſymmetry, and conſtituted what is now called Moſaic work. See the article MOSAIC.

In proceſs of time they came to attempt more regular deſigns, and alſo to repreſent figures heightened with all their ſhades; yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the ſame manner on glaſſes of the colour of the object they deſigned to paint. For the carnation, they uſed glaſs of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taſte for this ſort of painting improving conſiderably, and the art being found applicable to the adorning of churches, baſiliacs, &c. they found out means of incorporating the colours in the glaſs itſelf, by heating them in the fire to a proper degree, having firſt laid on the colours. The colours uſed in painting or ſtaining of glaſs are very different from thoſe uſed in painting either in water or oil colours. See the article COLOUR.

For black, take ſcales of iron, one ounce; ſcales of copper, one ounce; jet, half an ounce; reduce them to powder, and mix them. For blue, take powder of blue, one pound; ſal nitre, half a pound; mix them and grind them well together. For carnation, take red chalk, eight ounces; iron ſcales and litharge of ſilver, of each two ounces, gum arabic, half an ounce diſſolved in water; grind all together for half an hour very ſtiff; then put it in a glaſs and ſtir it well, and let it ſtand to ſettle fourteen days. For green, take red lead, one pound; ſcales of copper, one pound; and flint, five pounds; divide them into three parts; and add to them as much ſal nitre; put them into a crucible, and melt them with a ſtrong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, take ſilver, an ounce; antimony, half an ounce; melt them in a crucible; then pound the maſs to powder; and grind it on a copper plate; add to it yellow oker, or brick duſt calcined again, fifteen ounces; and grind them well together with water. For purple, take minium, one pound; brown ſtone, one pound; white flint, five pounds; divide them into three parts, and add to them as much ſal nitre as one of theſe parts; calcine, melt, and grind it as you did the green. For red, take jet, four ounces; litharge of ſilver, two ounces; red chalk, one ounce; powder them fine; and mix them. For white, take jet, two parts; white flint, ground on a glaſs very fine, one part; mix them. For yellow, take Spaniſh brown, ten parts; leaf ſilver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be ſeen the moſt beautiful and vivid colours imaginable, which far exceed any of thoſe uſed by the moderns, not ſo much becauſe the ſecret of making thoſe colours is entirely loſt, as that the moderns will not go to the charge of them, nor be at the neceſſary pains, by reaſon that this ſort of painting is not now ſo much in eſteem as formerly. Thoſe beautiful works which were made in the glaſs-houſes were of two kinds.

In ſome the colour was diffuſed through the whole ſubſtance of the glaſs. In others, which were the more common, the colour was only on one ſide, ſcarce penetrating within the ſubſtance above one third of a line; though this was more or leſs according to the nature of the colour; the yellow being always found to enter the deepeſt. Theſe laſt, though not ſo ſtrong and beautiful as the former, were of more advantage to the workmen, by reaſon that on the ſame glaſs, though already coloured, they could ſhew other kind of colours where there was occaſion to embroider draperies, enrich them with foliages, or repreſent other ornaments of gold, ſilver, &c.

In order to this, they made uſe of emery, grinding or wearing down the ſurface of the glaſs, till ſuch time as they were got through the colour to the clear glaſs. This done, they applied the proper colours on the other

ſide of the glaſs. By this means, the new colours were hindered from running and mixing with the former, when they expoſed the glaſſes to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glaſs was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights, and heightenings, or all kinds of colour.

The firſt thing to be done, in order to paint, or ſtain glaſs, in the modern way, is to deſign, and even colour the whole ſubject on paper. Then they chooſe ſuch pieces of glaſs as are clear, even, and ſmooth, and proper to receive the ſeveral parts, and proceed to diſtribute the deſign itſelf, or papers it is drawn on, into pieces ſuitable to thoſe of the glaſs; always taking care that the glaſſes may join in the contours of the figures, and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The diſtribution being made, they mark all the glaſſes as well as papers, that they may be known again: which done, applying every part of the deſign upon the glaſs intended for it, they copy, or transfer, the deſign upon this glaſs with the black colour diluted in gum water, by tracing and following all the lines and ſtrokes as they appear through the glaſs with the point of a pencil.

When theſe ſtrokes are well dried, which will happen in about two days, the work being only in black and white, they give a ſlight waſh over with urine, gum arabic, and a little black; and repeat it ſeveral times, according as the ſhades are deſired to be heightened, with this precaution, never to apply a new waſh till the former is ſufficiently dried.

This done, the lights and riſings are given by rubbing off the colour in the reſpective places with a wooden point or the handle of a pencil.

As to the other colours above-mentioned, they are uſed with gum-water, much as in painting in miniature; taking care to apply them lightly for fear of effacing the out-lines of the deſign; or even, for the greater ſecurity, to apply them on the other ſide; eſpecially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard muſt always be had not to lay colour on colour, or lay on a new lay, till ſuch time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glaſs, and incorporates therewith by the fire; the reſt, and particularly the blue, which is very difficult to uſe, remaining on the ſurface, or at leaſt entering very little. When the painting of all the pieces are finiſhed, they are carried to the furnace, or oven, to anneal, or bake the colours.

The furnace here uſed is ſmall, built of brick, from eighteen to thirty inches ſquare; at ſix inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three ſquare bars of iron, which traverſe the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a ſquare earthen pan, ſix or ſeven inches deep; and five or ſix inches leſs every way than the perimeter of the furnace. On the one ſide hereof is a little aperture, through which to make trials, placed directly oppoſite to that of the furnaces deſtined for the ſame end. In this pan are the pieces of glaſs to be placed in the following manner. Firſt the bottom of the pan is covered with three ſtrata, or layers, of quick lime pulverized; thoſe ſtrata being ſeparated by two others of old broken glaſs, the deſign of which is to ſecure the painted glaſs from the too intenſe heat of the fire. This done, the glaſſes are laid horizontally on the laſt or uppermoſt layer of lime.

The firſt row of glaſs they cover over with a layer of the ſame powder, an inch deep; and over this, they lay another range of glaſſes, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the ſame powder.

The pan being thus prepared, they cover up the furnace with tiles, on a ſquare table of earthen ware, cloſely luted all round, only leaving five little apertures, one at each corner, and another in the middle, to ſerve as chimnies. Things thus diſpoſed, there remains nothing but to give the fire to the work. The fire for the firſt two hours muſt be very moderate, and muſt be increaſed in proportion as the coction advances, for the ſpace of ten or twelve hours; in which time it is uſually completed. At laſt the fire, which at firſt was charcoal, is to be of dry wood, ſo that the flame covers the whole pan, and even iſſues out at the chimnies.

During the laſt hours, they make eſſays, from time to time, by taking out pieces laid for the purpoſe through the little aperture of the furnace and pan, to ſee if the yellow be perfect, and the other colours in good order. When the annealing is thought ſufficient, they proceed with great haſte to extinguiſh the fire, which otherwiſe would ſoon burn the colours, and break the glaſſes.

GLASS *of Lead*, a glaſs made with the addition of a large quantity of lead; of great uſe in the art of making counterfeit gems.

The method of making it is this: Put a large quantity of lead into a potter's kiln; and keep it in a ſtate of fuſion, with a moderate fire, till it is calcined to a very grey, looſe powder: then ſpread it on the kiln, and give it a greater heat, continually ſtirring it, to keep it from gathering into lumps; continue this ſeveral hours, till the powder become of a fair yellow; then take it out, and ſift it fine: this is called calcined lead. Take of this calcined lead fifteen pounds, and cryſtalline or other frit, twelve pounds; mix theſe well together; put them into a pot, and ſet them in the furnace for ten hours; then caſt the whole, which will now be perfectly melted, into water; ſeparate the looſe lead from it; and return the metal into the pot; and after ſtanding in fuſion twelve hours more, it will be fit to work. This glaſs is capable of all the colours of the gems in great perfection.

Log-GLASSES, in the marine, glaſſes that run a half minute and quarter-minute, to meaſure the ſhip's way at the time of heaving the log. See this operation fully explained under the article LOG.

Watch GLASSES, certain glaſſes to meaſure and divide the watches at ſea; they are of four and two hours, and of half an hour. See the article WATCH.

GLAUBER's SALT, a cathartic or purging ſalt, thus made. Take of the cake that remains after the diſtillation of Glauber's ſpirit of ſea-ſalt; diſſolve it in hot water, and filtre the ſolution through paper: then reduce the ſalt into cryſtals. It is given in doſes from half an ounce to an ounce.

GLAUCOMA, in ſurgery, a diſeaſe of the eye, wherein the cryſtalline humour is turned of a bluiſh or greenish colour, and its tranſparency thereby impaired. See CATARACT.

The word is Greek, and derived from γλαυκὸς, a ſea-green, or greyiſh colour.

GLAZIER, an artificer who works in glaſs, and whoſe principal buſineſs is in fitting panes of glaſs to ſaſhes, pictures, &c. and in making lead lights for window frames, and cleaning of ſaſh-windows, &c.

GLAZING, in pottery, a compoſition applied to veſſels of earth, &c. to render them more beautiful, and prevent fluids from penetrating them.

Black GLAZING is made of lead-aſhes, eighteen meaſures; iron-filings, three; copper-aſhes, three; and zaffer, two meaſures. This, when melted, will make a brown black; and, if you want it blacker, add more zaffer to it.

Blue GLAZING is thus prepared: take lead-aſhes, one pound; clear ſand or pebble, two pounds; ſalt, two pounds; white calcined tartar, one pound; Venice, or other glaſs, ſixteen pounds; and zaffer, half a pound; mix them well together, and melt them for ſeveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaſs furnace for a day or two.

Brown GLAZING is made of common glaſs and magneſe, or brown ſtone, of each one part; and lead of glaſs twelve parts.

W The PATENT GLOBES

Fleſh-colour GLAZING is made of twelve parts of lead-aſhes, and one of white glaſs.

Gold-coloured GLAZING. — To make gold-coloured glazing, take of litharge three parts; of ſand or calcined flint, one part; pound and mix theſe very well together, then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver, and make it into a paſte; which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire, then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that, by means of a hair pencil, you may apply it upon the veſſels, or any piece of earthen ware. The veſſels that are painted or covered over with this glazing, muſt be firſt well heated, then put under a muffle, and as ſoon as the glaſs runs, you muſt ſmoak them, and take out the veſſels. Mr. Heinſius of Peterſburgh, who ſent this receipt to the Royal Society, uſes the words *offlare debes fumum*, which is rendered ſmoak them, in the Tranſactions. Phil. Tranſ. N°. 466.

Green GLAZING may be prepared of eight parts of litharge, eight parts of Venice glaſs, four parts of braſs duſt; or of ten parts of litharge, twelve of flint or pebble, and one of æs uſtum, or copper aſhes.

Iron-colour GLAZING is prepared of fifteen parts of lead aſhes, fourteen of white ſand, five of copper aſhes, one of manganeſe, one of zaffer, and one of iron filings.

Liver-coloured GLAZING is prepared of twelve parts of litharge, eight of ſalt, ſix of pebble or flint, and one of manganeſe.

Purple-brown GLAZING conſiſts of lead aſhes, fifteen parts; clear ſand, eighteen parts; manganeſe, one part; white glaſs, fifteen meaſures; and one meaſure of zaffer.

Red GLAZING is made of antimony, two pounds; litharge, three; and ruſt of iron calcined, one; grind them to a fine powder.

Sea-green GLAZING is made of five pounds of lead aſhes, one pound of tin aſhes, three pounds of flint, three quarters of a pound of ſalt, half a pound of tartar, and half a pound of copper duſt.

White GLAZING. A fine white glazing for earthen ware is thus prepared: take two pounds of lead, and one of tin; calcine them to aſhes: of this take two parts, calcined flint or pebble, one part; and ſalt, one part; mix them well together, and melt them into a cake for uſe.

The white glazing for common ware is made of forty pounds of clear ſand, ſeventy-five pounds of litharge or lead aſhes, twenty-ſix pounds of pot-aſhes, and ten pounds of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of fifty pounds of clean ſand, ſeventy of lead aſhes, thirty of wood aſhes, and twelve of ſalt.

Yellow GLAZING is prepared of red-lead, three pints; antimony and tin, of each two pounds. Theſe muſt be melted into a cake, then ground fine; and this operation repeated ſeveral times. Or it may be made of fifteen parts of lead ore, three parts of litharge of ſilver, and fifteen parts of ſand.

Citron-yellow GLAZING is made of ſix parts of red-lead, ſeven parts of fine red brick-duſt, and two parts of antimony.

GLEBE, among miners, ſignifies a piece of earth, wherein is contained ſome mineral ore. See ORE.

GLEBE, in law, the land belonging to a pariſh church, beſides the tithes.

GLEET, in medicine, the flux of a thin limpid humour from the urethra. See GONORRHŒA.

GLENE, γλανη, in anatomy, a ſhallow cavity of any bone, which receives another bone in articulation. It alſo ſignifies the cavity or ſocket of the eye.

GLOBE, in the language of geometers, is a round ſolid body, formed by the rotation of a ſemi-circle about its diameter, remaining fixed until it return to the place again from whence it began to move; whence that point which was before in the middle of the diameter, and was the center of the generating circle, becomes now the center of the globe itſelf, as being equally diſtant from every point in the generated ſurface.

The artificial ſpherical body, from the exact ſimilitude it has to our ball of earth, as has been proved from manifold obſervations, and particularly from the obſervations made of eclipſes, has been choſen by geographers, as the fitteſt and propereſt inſtrument to delineate upon its outward ſurface the external appearance of this our globe; ſo that the terreſtrial globe is an artificial repreſentation of this our terraqueous globe, upon whoſe convex ſuperficies the form of the habitable world is delineated, and all the parts of the earth and ſea are deſcribed in their natural form, order, diſtance, and ſituation. See plate LXXI. *fig.* 2.

And becauſe the celeſtial bodies appear to us as if they were all placed in the ſame concave ſphere, aſtronomers have likewiſe made uſe of the external ſurface of the globe, to lay down the ſtars upon in their juſt and due poſition and diſtance, and according to their ſeveral magnitudes. So that as the terreſtrial globe is an artificial repreſentation of the ſurface of this our terraqueous globe, as it would appear to us if placed at a convenient diſtance without it, and we could either be conveyed round it, or view it revolving about its own axis; ſo the celeſtial globe is alſo an artificial and lively repreſentation of the ſtarry heaven, ſuppoſing ourſelves placed in the center and the globe to be tranſparent, as it appears to us, when placed upon the convex ſurface of the earth; and which, conſidering its infinite ſmallneſs, with regard to the unmeaſurable diſtance of the fixed ſtars, may be conſidered as the center of the univerſe. See *fig.* 3.

And as the geographers, for the ready diſtinction of places, have divided the ſurface of the earth into ſeveral parts, ſuch as Europe, Aſia, &c. and theſe are divided again into empires, kingdoms, &c. ſo the aſtronomers, that they may the better diſtinguiſh the fixed ſtars from one another, have in like manner divided them into ſeveral aſteriſms or conſtellations, each of which contains a ſyſtem of ſeveral ſtars that are ſeen in the heavens near to one another; and have reduced theſe conſtellations into the forms of certain animals, ſuch as bulls, bears, lions, men, &c. or in the image of things known to us, as of a crown, a harp, &c. which were eſteemed by the ancients upon religious and civil accounts, and are ſtill retained by the modern aſtronomers, to avoid that confuſion which would neceſſarily follow, in comparing their obſervations with thoſe that were formerly made.

And as the ancient aſtronomers for theſe reaſons very judiciouſly incloſed almoſt all the fixed ſtars that were known to them, in about forty eight conſtellations, ſo their ſucceſſors with equal right, when, by their diligent and frequent obſervations, they had greatly increaſed the number of ſtars in their catalogue, filled up moſt of the chaſms with new conſtellations of their own, and which are ſtill retained with great advantage to the obſervators.

Hence it appears that globes are not only the moſt proper contrivances for accounting for all the heavenly appearances ariſing from the diurnal and annual motion of the ſun, or the rotation of the earth about her own axis; but the nobleſt inſtrument as well for informing the mind, and giving it the cleareſt and moſt diſtinct idea of the thing propoſed to be done, as for giving ſolutions to all problems reſulting from it; and it is from a contemplation of theſe bodies and their ſeveral appendages, that aſtronomers have diſcovered ſo many excellent methods for the more eaſy and exact ſolution of the ſeveral aſtronomical and geographical propoſitions; whence it muſt be allowed, that to have a perfect knowledge of them is one of the ſureſt and beſt foundations that can be laid, by any one who would underſtand aſtronomy, geography, navigation, and their dependent ſciences.

Now in order to lay down the places of the ſtars upon the globe in their due ſituation and order, as well as to tranſfer the ſeveral diviſions of the earth, and to deſcribe on the terreſtrial globe the irregular terminations of land and ſea, it was abſolutely neceſſary to have ſome fixed or certain points, and conſequently lines, to begin to countor meaſure from; and this put mankind upon contriving thoſe ſeveral circles that are deſcribed upon the ſurface of the globes, which have their names given to them, ſome

according to the uſes for which they are deſigned, and others upon the account of thoſe places that they are ſuppoſed to poſſeſs; which circles the reader ought to be very well acquainted with, and of which he will meet with a full account under the article SPHERE.

We ſhall therefore proceed to give an account of the ſeveral appurtenances belonging to the globes.

1. The horizon is that great broad circle that divides the globe into two equal parts, termed the upper and lower hemiſpheres.

This circle is diſtinguiſhed into two kinds; the one is called the ſenſible or natural horizon, and is that circle which bounds the utmoſt proſpect of our ſight, when we view the heavens round from any part of the ſurface of the earth or ſea; the other is called the true or mathematical horizon, to which all aſtronomical calculations refer, and which obtains only in the mind, and ſuppoſes the eye to be placed in the very center of the earth, beholding half of the entire firmament at one view; which is repreſented by the uppermoſt ſurface of that broad wooden circle E (*fig.* 2.) upon the upper ſurface of the frame in which the globe is fixed, having two notches, the one in the north and the other in the ſouth part of it, for the brazen meridian to ſtand in.

And as the globe is made to ſlide up and down in theſe notches, this circle is of great uſe in determining the times of the riſing and ſetting of the ſun or ſtars, and their continuance above the horizon; in ſhewing us the reaſon of the increaſe and decreaſe of the length of the day and night, &c. in all places upon the earth by inſpection. Upon this broad horizon are deſcribed ſeveral other ſmall circles.

The firſt or innermoſt contains the twelve ſigns of the zodiac, each ſign being equal to thirty degrees. In the ſecond they are diſtinguiſhed by their proper names, marks, or characters. The third contains the days and months of the year, with the times when the principal fixed feaſts or faſts are to be celebrated.

The outermoſt circle contains the points of the compaſs with the names of the winds, as they are called by our ſeamen.

The next great circle B L D is the meridian, and is repreſented by the brazen frame or circle in which the globe is hung by the two wires which repreſent the two poles of the world, or the two extremities of the axis on which the globe hangs; within which it turns, dividing the globe in two equal parts, called the eaſtern and weſtern hemiſpheres, and from its being made of braſs is generally termed the brazen meridian. This circle is divided into four quadrants anſwering to 360 degrees, the entire circumference of every circle, two of which commence at the equator and increaſe towards each pole, in order to ſhew the declination of the ſun or ſtars on the celeſtial globe, and the latitudes of places on the terreſtrial globe; and the other two 90 degrees commence at either pole, and increaſe towards the equator for the more eaſy and ready adjuſting of the globe to the latitude of any particular place; for as the globe hangs in the meridian, and this is made to ſlide eaſily through the notches made in the north and ſouth points of the horizon, it is very eaſy to elevate or depreſs either pole of the globe, ſo as that it ſhall ſtand at any particular elevation.

And as the globe is made to turn within this circle, upon the two extremities of the axis, called the two poles, this brazen meridian may be made to repreſent the meridian of any place upon the terreſtrial globe, or a circle of right aſcenſion, to any point whatſoever upon the celeſtial globe, and is of great uſe in the ſolution of all problems relating to either globe.

The next great circle is the equinoctial, as it is called on the celeſtial globe, or the equator on the terreſtrial, and divides the globe into two equal parts, called the northern and ſouthern hemiſpheres; this circle is of uſe in determining the right aſcenſion of the ſun or ſtars on the celeſtial globe, and the longitudes of places on the terreſtrial.

The next great circle is the ecliptic, divided into twelve ſigns, and each ſign into thirty degrees, dividing the globe into two equal parts, called the northern and ſouthern hemiſpheres, with regard to the latitudes of the fixed ſtars and planets.

The ſun in his annual motion, according to Ptolemy, paſſes through the ecliptic, and if we add to it a broad ſpace of about eight degrees on each ſide, we ſhall have the zodiac, in which are the twelve aſteriſms, the moſt of which having the likeneſs of ſome living creature, was the occaſion of giving it this name; and becauſe the greateſt latitude of any of the planets never amounts to eight degrees, the motion of the moon, as well as of the reſt of the planets, will always be performed in this ſpace.

The quadrant of altitude is a narrow thin plate of pliable braſs, exactly anſwering to one fourth part of the meridian, and divided into 90 degrees, having a notch, nut, and ſcrew at one end, to faſten it to the zenith in the meridian; and being thus fixed and turned round upon a ſmall pivot, it ſupplied the place of an infinite number of vertical circles, and is very uſeful in determining the altitudes and azimuths of the celeſtial bodies, and in finding the times, &c.

The hour circle is a flat ring of braſs A B, ſo contrived that it may be taken off and fixed about either pole of the globe; and when it is ſo faſtened to the brazen meridian, the pole becomes its center, and to that end of the axis there is fixed an index that turns round as the globe itſelf is turned round, and points out upon the horary circle the hour given or required; for this horary circle being the repreſentation of the equator, which is carried about in one day, upon its upper ſurface are inſcribed the twenty-four hours of the natural day, at equal diſtances from one another; the twelfth hour next towards the zenith repreſenting twelve at noon, and the other neareſt the nadir repreſenting twelve at night; and the hours on the eaſtern ſide repreſenting the morning hours, and thoſe on the weſtern ſide repreſenting the afternoon hours; each hour anſwering to or correſponding with fifteen degrees of the great equinoctial, and is placed there for no other reaſon, but to ſave the trouble of reducing the degrees of the equinoctial into time, and the contrary.

The ſemi-circle of poſition, which is rarely or ever affixed to the globe, is a narrow thin plate of braſs, exactly anſwering to one half of the horizon divided into 180 degrees, and uſually affixed to the north and ſouth ends of the horizon or meridian, and is of uſe in making out the cuſps of the twelve houſes, as they are uſually called, in meaſuring the diſtances between any two places upon the ſurface of the earth, or any two ſtars upon the celeſtial globe, and may ſerve for a double quadrant of altitude, &c. And laſtly, if a mariner's compaſs, duly touched with a loadſtone, be fixed upon the pediment or wooden frame which contains the globe, or in ſome part of the broad wooden horizon, ſo that the true meridian of the compaſs may lie exactly parallel to the plane of the brazen meridian; the globes are prepared for any uſe to which they may be applied, and ready for the ſolutions of all problems that can be propoſed relating to them.

Problems more immediately relating to the terreſtrial GLOBE.

1. To find the diſtance between two places upon the globe: lay the quadrant of altitude upon the globe, ſo that the graduated edge may paſs through both the places, and obſerve how many degrees and minutes are between them: or thus, with a pair of compaſſes, ſet one foot upon the place, and open the compaſſes till the other foot ſtands upon the other place, then carry this diſtance to the equator, and ſetting one foot of the compaſſes upon the firſt meridian, obſerve how many degrees and minutes it is, which you may turn into Engliſh miles, by multiplying by 69.5.

2. To find all places that are at a given diſtance from a place given: for example, to find all places that are ten degrees from London; open a pair of compaſſes till they meaſure ten degrees upon the equator, then ſetting one foot upon London, turn the other round, and it will paſs through all the places that are ten degrees from London. By the ſame method we find all places that are at an equal diſtance from any given place: thus ſetting one foot of a pair of compaſſes upon London, and turning the other round through Rome, we ſee all places that are at the ſame diſtance from London that Rome is; as alſo what places are nearer to, or further from, London than Rome is.

3. To find the latitude of any place upon the globe: bring

bring the place to the meridian, and the degree and minute under which it lies ſhew its latitude; thus, bring London to the meridian, as in *fig.* . and it appears to be in 51° 31′ north latitude. If a place lying under the equator be brought to the meridian, the mark over it will be 00, becauſe it has no latitude. See LATITUDE.

4. To find all places which have the ſame latitude with a given place: ſuppoſe the given place be London, turn the globe round, and all places that paſs under the ſame point of the meridian that London doth, have the ſame latitude with London. To find the difference of latitude of two given places of the globe, as London and Paris: find the latitude of each place, and the difference is eaſily known.

5. To find the longitude of any place upon the globe: bring the place to the meridian, and the degree and minute of the equator the meridian then paſſes through is the longitude: thus, if Rome be brought to the meridian, its longitude will appear to be 12° 45′, upon our Engliſh globes, which have the firſt meridian drawn through London.

6. To find all places which have the ſame longitude with a given place, as Naples, it is ſufficient to bring Naples to the meridian; for all places then under the meridian have the ſame longitude with Naples; to find the difference of longitude of two places, find the longitude of each, and the difference is eaſily known.

7. To find a place upon the globe, its longitude and latitude being given: let the place be Aracta, the longitude of which is 44°. 55′, eaſt, from London, and latitude 36°. 0′ north: bring 44°. 55′ of the equator to the meridian, and under the 36°. of north latitude is Aracta, or the place where it ought to be: for this method will ſerve to inſert a place upon the globe, its longitude and latitude being given.

8. To rectify the globe to the latitude of any place: let the place be London, which lies in 51° 31′ north lat. move the braſs meridian in the notches till the north pole of the globe is elevated 51° 31′ above the north ſide of the horizon, that is, till the elevation of the pole is equal to the latitude, as in *fig.* 2.

9. To rectify the globe to the horizon of any place, as London: rectify the globe to the latitude of London, and bring London to the meridian; the horizon of the globe will then repreſent the horizon of London.

10. To find towards what place of the compaſs any place lies from a given place: if it be enquired towards what point of the compaſs Liſbon lies from London, rectify the globe to the horizon of London, ſcrew the center of the quadrant of altitude to the zenith point of the meridian, and turn the other end round till the graduated edge paſſes through Liſbon; then obſerve what point of the horizon in the circle in the winds the graduated edge paſſes through, which in the preſent caſe will be ſouth-weſt by ſouth, we ſay then Liſbon lies ſouth-weſt by ſouth from London.

11. To find the angle of poſition between any place and a given place: if it be enquired what is the angle of poſition of Liſbon and London, that is, what angle a great circle drawn through thoſe two places makes with the meridian of London, do every thing directed in the laſt problem, and obſerve how many degrees of the horizon are contained between the graduated edge of the quadrant altitude and meridian, which in the preſent caſe will be 33° 45′; the angle of poſition of Liſbon with regard to London is then 33° 45′.

12. To rectify the globe to the meridian of the place where we are, which is the ſame thing as to rectify the globe to the ſituation the earth is in every day when it is noon at that place: ſuppoſe the place is London, rectify the globe to the horizon of London, then turn the frame of the globe about till the north and ſouth points of the horizon of the globe are towards the north and ſouth: the ſouth may be known by the ſun at noon; the north by the pole-ſtar any time of the night: the globe may alſo be rectified to the meridian of any place, by a meridian line, or by a magnetic needle in a compaſs-box.

13. To rectify the globe to the preſent ſituation of the earth at any hour of the day: if you be in London, and would bring the globe into the ſituation the earth is in at four in the afternoon; rectify the globe to the meridian of London, and ſince the rotation of the earth carries the meridian and hour circles of London upon the globe coinciding with the like circles upon the earth, the ſituation of the globe will then correſpond to that of the earth; and if it ſtands in the ſun, it will be illuminated as the earth is.

14. The hour of the day being given at one place, as London, to find what hour it is at any other place upon the globe, as Naples: rectify the globe to the horizon of London, ſet the hour index at twelve at noon, turn the globe round till Naples is at the meridian, the index will then ſhew what hour it is at London, when it is noon at Naples: thus, if it points at 11 in the morning, it ſhews that it is 11 in the morning at London, when it is noon at Naples; and conſequently, whatever is the time given at London, the time of the day at Naples is an hour forwarder in the day; as if it be two in the afternoon at London, it is three in the afternoon at Naples, &c.

15. By knowing the time of any particular phænomenon, to find its poſition in the heavens, and where it may be viſible: bring that part of the globe to which the ſun, moon, or planet, will be vertical at the given time, to the zenith; then will ſuch phænomena as are momentary, be viſible to all the inhabitants of the earth that are now above the horizon: and if you rectify the quadrant, and lay it over each particular place, it will ſhew the altitude of it, as alſo the azimuth; oppoſite to which in the heavens is the vertic circle, in which the object will be found.

Thus the middle poſition of an eclipſe, tranſit, or occultation of the heavenly bodies may be nearly determined to any given place upon earth; but for the beginning and end of the ſame, a new operation will be required.

Problems more immediately relating to the Celeſtial GLOBE.

1. To find the right aſcenſion and declination of any ſtar. The given ſtar being found, bring the center of it to the ſouth-part of the meridian; then, right above it, you will find the declination, and in the equinoctial, the right aſcenſion: the former in the meridian, the latter cut by it.

2. To find the latitude and longitude of any ſtar, and the place of any ſtar, and the place of any planet, if marked on the globe: Firſt, bring the ſolſtitial colure to the brazen meridian, that is, to be directly under it: then elevate or depreſs the pole of that hemiſphere, in which the ſtar is found, till the poles of the ecliptic be exactly in the zenith and nadir, that is, till the ecliptic coincide with the horizon; keeping the globe in this poſition, rectify the quadrant of altitude, and move it till its graduated edge paſs or lie juſt over the center of the given ſtar, and there fix it. Then ſee what degree lies over-againſt the ſtar's center on the quadrant, and what portion of the ecliptic, now lying in the horizon, is cut by the quadrant, and the former will be the latitude of the ſaid ſtar, and the latter its longitude from Aries.

3. To find the riſing and ſetting of any ſtar, &c. The globe being rectified, bring the ſtar, whoſe riſing is required, to the eaſt part of the horizon; then the index of the hour circle will ſhew the hour and minute of its riſing; and in like manner, if the globe is turned to the weſt, it will ſhew the ſetting.

N. B. The riſing and ſetting of any ſtar being found in hours and minutes, the one ſubſtracted from the other, that is, the firſt from the laſt, gives the nocturnal arch, or the time of its ſtay above the horizon: but if the ſetting be leſs than the riſing, add twelve hours thereto, and from the whole deduct the riſing, and there will remain the ſum required.

4. To know at any time what ſtars are aſcending or deſcending, move the globe about, all things being rectified as above, to the given hour, and there fix it; and then obſerving what ſtars lie even with the horizon, thoſe on the eaſt ſide are ſaid to be riſing, and thoſe to the weſt ſetting. Thoſe under the meridian are ſaid to be culminating, being then full ſouth; as thoſe on the eaſt ſide of the globe are aſcending, and thoſe on the weſt deſcending, what are below the horizon being inviſible. Laſtly, if you place the quadrant of altitude over the center of any particular ſtar, it will ſhew you its altitude, and at the ſame time gives, upon the horizon, the azimuth required.

5. How to diſtinguiſh one ſtar from another in the heavens, and know them by their names on the globe. The meridian being placed due north and ſouth, and the globe rectified to the time and latitude required, each part of the globe will correſpond with its reſpective conſtellation in the heavens; ſo that if the globe was tranſparent, and the obſerver's eye placed in the center, every artificial ſtar painted upon it would appear concentric with the real one.

To find their amplitude, and their oblique aſcenſion or deſcenſion, obſerve what degree of the equator riſes or ſets with each, or any one of them, and that is the thing required; or if the amplitude be deſired, ſee upon what point of the compaſs they firſt appear, and then that diſtance from the eaſt, or weſt point of the horizon, reduced into degrees, will give the quantity of the amplitude required.

6. To find the hour of the night. The globe being rectified, bring the given ſtar to the quadrant of altitude, and ſee that the known elevation, which in this caſe muſt always be taken by obſervation with an inſtrument, be cut thereby, then will the hour index point to the time required; or if any known ſtar be in the meridian, the hour will be ſhewn, without knowing the altitude by the index only.—In like manner may be found the hour of the day by the ſun, his altitude being given.

7. To know what ſtars are viſible in any latitude, and in what latitude any particular ſtar firſt appears: rectify the globe according to the latitude of the place required, and then, turning it round, you will, according to the ſeaſon of the year, find what conſtellation will be viſible at that time.

If again you bring any particular ſtar to the meridian, and move the globe ſo as to bring the ſaid ſtar to the horizon, you will find, by allowing for the denſity of the atmoſphere in proportion to their ſeveral magnitudes, in what latitude it will firſt become viſible.

N. B. All thoſe ſtars whoſe diſtance from the elevated pole is leſs than the latitude of the place, never ſet to their reſpective inhabitants; as their oppoſite ones, being equally depreſſed, never riſe.

Patent GLOBES, thoſe with Mr. Neale's improvements, for which he obtained his majeſty's letters patent.

The terreſtrial globe, with theſe improvements, is repreſented in plate LXXI. *fig.* 4. the earth being ſuppoſed in that part of its orbit where the north-pole A is at its neareſt approach to the ſun S, which accordingly by the index or ray S R, points to the tropic of Cancer; *b* is a moveable circle, which, ſet to the latitude of a given place, will cauſe the ſemicircle *c* to point out the zenith of the ſaid place; *d* repreſents the ecliptic, *e* the equator, and *f* a ſcrew by which the annual motion may be ſeparated from the diurnal; *g* is a ſemi-circle which always moves at 90 degrees diſtance from the moon, and thereby becomes the lunar horizon for the northern hemiſphere; *h* is an inclined plane on which the ſtem of the moon P O moves, thereby cauſing the moon itſelf to ſhew its ſeveral latitudes, nodes, &c. and by this plane moving the contrary way, in a little more than nineteen of the annual revolutions of the globe, is ſhewn the retrograde motion of the nodes.

This globe is mounted with the horizon *a* fixed vertically, and placed ſo as to move upon its own axis A H, whereby it repreſents the diurnal motion of the earth. Hence if the globe be turned round its own axis, by means of the winch at top, the ray from the ſun will, in this ſituation, deſcribe the tropic of Cancer: the whole arctic circle will be taken into the enlightened hemiſphere, and that of the antarctic circle will be involved in darkneſs. Let us now ſuppoſe the globe turned thirty times about by the winch, the north-pole will then be ſituated as at B, and the index from the ſun will point to the ſign Leo on the ecliptic *d*: after turning the globe thirty times more, the north-pole will be removed to C, and the index advanced to Virgo; and in this manner may the phænomena of the earth's annual motion be traced through all the ſigns of the ecliptic and ſeaſons of the year; the index or pointer deſcribing a ſpiral line, which every day at noon, or turn of the globe, falls at the diſtance of about fifteen minutes from that of the preceding day. When the earth is ſo far advanced in its orbit, that the index S R points to the equator, the reaſon will appear very clear why the days and nights are then equal all the world over; for both poles are now ſeen in the horizon, which, being the boundary of light and darkneſs, biſects all the parallels of latitude, and cauſes an equal diſtribution of day and night throughout the whole earth.

If the rotation of the globe be continued, the obſerver will ſee the north-pole deſcend juſt as many degrees below the horizon, as the pointer has advanced ſouth of the equator; and when it is arrived at the tropic of Capricorn, all that part of the globe within the arctic circle will be involved in continual darkneſs, whilſt that within the antarctic circle enjoys uninterrupted day.

At the diſtance of 90 degrees from the moon, as has been already obſerved, is placed a ſemi-circle, which being fixed on the center of the moon's motion, always moves round with her; thereby ſhewing, throughout her courſe, all thoſe countries in the northern hemiſphere, to which ſhe is at any particular time riſing, thoſe where ſhe is then ſetting, and thoſe to whom ſhe is then due ſouth; as alſo the exact difference of time between the riſing or ſetting of the ſun and moon.

The celeſtial globe (*fig.* 5.) is mounted not quite ſo differently from the common globes, as the terreſtial one; its horizon being as uſual, and the globe moveable to the latitude of any country; only inſtead of thoſe upright pillars to ſupport the horizon, as in common ones, here ſemicircles are fixed on the pedeſtal, and from the pole of the equator a motion is conveyed to the pole of the ecliptic; where two arms or indexes are placed, on which are fixed the artificial ſun and moon. Theſe, as the globe is turned about its axis by the winch W, keep their exact motions over the ſame, by means of the wheel-work at Q, in like manner as thoſe luminaries do in the heavens; ſo that being once ſet right by an ephemeris, they will remain ſo, and thereby ſhew the riſing and ſetting of thoſe luminaries, with the length of the day and night, together with the true cauſe of all the viciſſitudes of the ſeaſons; and how, notwithſtanding their apparent motion from eaſt to weſt, they really move from weſt to eaſt; the moon, in a very little more than twenty-nine days and a half; and the ſun, in a year. See EARTH, SUN, and MOON.

To the center of the ſun two jointed ſtems are occaſionally ſcrewed on, and to theſe are fixed Mercury and Venus; which by the ſaid joints may be ſet to their proper ſtations, and thereby ſeveral entertaining problems may be ſolved.

From what has been ſaid it is evident, that the uſual problems on the common globes, and moſt of thoſe with the orrery, may be ſolved by theſe curious machines.

Problems peculiar to the patent GLOBES.—1. *To rectify theſe globes.* This, on the celeſtial globe, is performed in the ſame manner as on the common globes: but the terreſtrial globe admits of no ſuch rectification; for inſtead of raiſing or lowering the pole of the globe itſelf, according to the latitude of the place, we muſt here rectify a moveable brazen horizon, ſo as that the given place ſhall be in the zenith of the ſaid horizon. 2. *To rectify the ſun and moon according to theſe globes.* Having found the ſun's place in the ecliptic, in the common way, turn the ſun about by its ſtem till it is directly oppoſite to the ſame ſign and degree of the ecliptic upon the globe. The ſame may alſo be done with reſpect to the moon, having firſt found her place by an ephemeris for that day. 3. *To ſhew on theſe globes the cauſe of an eclipſe of the ſun or moon.* This is ſelf-evident on either globe, by turning them by the winch till the two luminaries come in conjunction with, or oppoſition to each other, provided they happen to be in or near the nodes. 4. *To explain the reaſon why they happen no oftener.* This will appear no leſs evident, by ſetting the moon to any conſiderable latitude, and turning the globe till ſhe comes in conjunction with the ſun; for then the pointer from the ſun will be ſeen to paſs either above or below her, according as ſhe is in north or ſouth latitude; ſo that there can be no eclipſe of the ſun, when the moon is not in or near her nodes. 5. *To exhibit a natural repreſentation of the retrograde motion of the moon's nodes.* This is done by only turning the globe with the winch, and obſerving that the place where the moon

moon croſſes the ecliptic, in its motion round the earth, is every time in different places; which are found to be retrograde, or contrary to the order of the ſigns; that is, they move backward through all the ſigns from eaſt to weſt. 6. *The day and hour of a ſolar eclipſe being given, to find all thoſe places on the globe to which the ſame will be viſible.* Turn the globe till the given day comes oppoſite to the ſun, and the place where you are to the pointer; ſet the index to 12, then turn the globe till the index points to the given hour; ſet the moon in conjunction with the ſun; then all the places above the ſolar horizon are thoſe to which the eclipſe will be viſible. 7. *To find the ſame in a lunar eclipſe.* Proceed as in the laſt problem; only inſtead of the moon's being in conjunction, ſhe muſt now be in oppoſition; and inſtead of viewing all the countries on that ſide of the horizon towards the ſun, you muſt ſurvey thoſe on the oppoſite ſide; for they are the countries to which the lunar eclipſe will be viſible. 8. *To exhibit the phaſes of Mercury and Venus.* Set them to any given ſtation within the enlightened hemiſphere of the celeſtial globe; and it may be obſerved, that their different phaſes in thoſe ſeveral ſtations will be in all reſpects analogous to thoſe of our moon. 9. *To demonſtrate, that in a certain latitude, the inhabitants may obſerve the ſun, moon, Mercury, and Venus, all riſing together on a particular day; and yet, on the ſame day, may ſee the moon ſet twelve hours before the ſun, Mercury fourteen hours after the moon, and Venus ſix hours after all three.* Rectify the globe to the latitude of 66 ½; let the moon riſe near the tropic of Capricorn, the ſun at the beginning of Aries, Mercury about fifteen degrees in Aries, and Venus about eighteen degrees in Taurus, with five or ſix degrees of north latitude; then turn the globe about, and you will find by the index the difference of time ſought for. 10. *To find the height of the diurnal arch of the luminaries and planets aforeſaid, on any given day.* The globe being rectified, ſcrew the quadrant of altitude to the zenith of the place, which bring to the meridian; then turn about the globe to the given day, and the degree of the quadrant, each reſpectively paſs over, is the height of their arches ſought. 10. *To ſhew why neither Mercury nor Venus can be ſeen on the meridian of London at midnight, as all the other planets at certain times are.* Set theſe two planets to their greateſt elongation or diſtance from the ſun; and by turning the globe about the impoſſibility of the thing will be evident.

GLOBULAR, in general, an appellation given to things of a roundiſh figure, like that of a globe.

GLOBULAR *Projection.* See MAP.

GLOBULE, a diminutive of globe, frequently uſed by phyſicians in ſpeaking of the red ſpherical particles of the blood. See BLOOD.

GLORIA PATRI, among eccleſiaſtical writers. See DOXOLOGY.

GLORIOSA, ſuperb lilly, in botany, a genus of plants, the flower of which conſiſts of ſix oblongo-lanceolated, undulated, and very long petals, reflex nearly to the baſe; the fruit is an oval pellucid capſule, containing three cells, and numerous globoſe ſeeds, diſpoſed in a double ſeries.

GLOSS, in matters of literature, denotes an expoſition or explication of the text of any author, whether in the ſame language, or any other; in which ſenſe it differs little from commentary. See COMMENTARY.

GLOSS, among artificers, the luſtre or brightneſs ſet upon cloth, ſilk, and the like. See CLOTH, SILK, &c.

GLOSSARY, *Gloſſarium*, a ſort of dictionary, explaining the obſcure and antiquated terms in ſome old author; ſuch are Du Cange's Latin and Greek Gloſſaries, Spelman's Gloſſary, and Kennet's Gloſſary at the end of his Parochial Antiquities.

GLOSSOCOMON, in ſurgery, an inſtrument, or ſort of caſe, contrived by the ancient ſurgeons, for containing a fractured leg or thigh.

GLOSSOCOMON, in mechanics, the name by which Hiero calls a machine, compoſed of ſeveral dented wheels with pinions, and uſed for raiſing great weights.

GLOSSOPETRA, in natural hiſtory, a genus of extraneous foſſils, ſo called from their having been ſuppoſed the tongues of ſerpents turned to ſtone, though they are really the teeth of ſharks, and are daily found in the mouths of thoſe fiſhes, wherever taken.

GLOTTIS, in anatomy, the mouth or aperture of the larynx, through which the air aſcends and deſcends in reſpiring. It is of an elliptic figure, and furniſhed with cartilages and muſcles, by means of which it is occaſionally dilated or ſtraitened, ſo as to give that wonderful variety of notes, of which the voice is capable, in ſpeaking and ſinging. See the article LARYNX.

GLOW-WORM, the Engliſh name of an inſect, called by zoologiſts cicindela. See the article CICINDELA.

GLUE, among artificers, a tenacious viſcid matter, which ſerves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uſes they are deſigned for, as the common glue, glove-glue, and parchment glue; whereof the two laſt are more properly called ſize. See SIZE.

The common or ſtrong glue is chiefly uſed by carpenters, joiners, cabinet-makers, &c. and the beſt kind is that made in England, in ſquare pieces of a ruddy brown colour; and, next to this, the Flanders glue. It is made of the ſkins of animals, as oxen, cows, calves, ſheep, &c. and the older the creature is, the better is the glue made of its hide. Indeed, whole ſkins are but rarely uſed for this purpoſe, but only the ſhavings, parings, or ſcraps of them; or the feet, ſinews, &c. That made of whole ſkins, however, is undoubtedly the beſt; as that made of ſinews is the very worſt.

The Method of making GLUE. In making glue of parings, they firſt ſteep them two or three days in water; then waſhing them well out, they boil them to the conſiſtence of a thick jelly; which they paſs, while hot, through ozier-baſkets, to ſeparate the impurities from it, and then let ſtand ſome time, to purify it further: when all the filth and ordures are ſettled to the bottom of the veſſel, they melt and boil it a ſecond time. They next pour it into flat frames or moulds, whence it is taken out pretty hard and ſolid, and cut into ſquare pieces or cakes. They afterwards dry it, in the wind, in a ſort of coarſe net; and at laſt ſtring it, to finiſh its drying. The glue made of ſinews, feet, &c. is managed after the ſame manner; only with this difference, that they bone and ſcour the feet, and do not lay them to ſteep.

The beſt glue is that which is oldeſt; and the ſureſt way to try its goodneſs, is to lay a piece to ſteep three or four days, and if it ſwell conſiderably without melting, and when taken out reſumes its former drineſs, it is excellent.

A glue that will hold againſt fire or water, may be made thus: mix a handful of quick-lime with four ounces of linſeed-oil; boil them to a good thickneſs, then ſpread it on tin-plates in the ſhade, and it will become exceeding hard, but may be eaſily diſſolved over a fire, as glue, and will effect the buſineſs to admiration.

Method of preparing and uſing GLUE. Set a quart of water on the fire, then put in about half a pound of good glue, and boil them gently together till the glue be entirely diſſolved and of a due conſiſtence. When glue is to be uſed, it muſt be made thoroughly hot; after which, with a bruſh dipped in it, beſmear the faces of the joints as quick as poſſible; then clapping them together, ſlide or rub them lengthwiſe one upon another, two or three times, to ſettle them cloſe; and ſo let them ſtand till they are dry and firm.

Fiſh-GLUE, a name ſometimes given to ichthyocolla. See ICHTHYOCOLLA.

GLUME, *Gluma*, among botaniſts, a kind of cup, conſiſting of two or three membranous valves, which are often pellucid at their edges. This ſort of cup belongs to the graſſes.

GLUTÆUS, in anatomy, the name of three muſcles, which form the buttocks, and from their ſize are called maximus, medius, and minimus. They all ariſe in the external ſurface of the ilium, iſchium, and os ſacrum: the termination of the firſt, or greateſt, is about four fingers-breadth from the great trochanter, and the terminations of the two others are in this trochanter.

GLYCINE, ſcarlet-pea, in botany, a genus of plants, with a papilionaceous flower, and an oblong bilo-

cular pod, containing a number of kidney ſhaped ſeeds, of a ſcarlet colour, ſpotted with black.

GLYCONIAN VERSE, in ancient poetry, conſiſts of three feet, whereof the firſt is a ſpondee, the ſecond a choriambus, and the laſt a pyrrhichius; or the firſt may be a ſpondee, and the other two dactyls.

GLYCYRRHIZA, liquorice, in botany, a genus of plants, with a papilionaceous flower, conſiſting of four petals; the fruit is an oblong, compreſſed, and uniloçular pod, containing a few kidney-ſhaped ſeeds.

GLYPH, in ſculpture and architecture, denotes any canal or cavity, uſed as an ornament.

GLYSTER, or CLYSTER, among phyſicians. See CLYSTER.

GNAPHALIUM, cudweed, in botany, a genus of plants, with numerous hermaphrodite flowers on its diſc, and a few female ones on the verge; there is no pericarpium; the ſeeds, which are oblong, ſingle, and crowned with down, being contained in the cup.

GNAT, in zoology, an inſect of the fly-kind, called by authors culex. See CULEX.

GNOME is often uſed in a ſynonymous ſenſe with apophthegm. See APOPHTHEGM.

GNOMES, *Gnomi*, certain inviſible people, who, according to the Cabbaliſts, inhabit the inner parts of the earth. They are ſuppoſed ſmall in ſtature, and the guardians of quarries, mines, &c. See the article CABBALISTS.

GNOMON, in dialling, is the ſtyle or pin of a dial, whoſe ſhadow ſerves to point out the hour.

The word is Greek, and derived from γνωμων, which imports ſomewhat that makes known; becauſe the ſtyle indicates the hour.

The gnomon of every dial is ſuppoſed to repreſent the axis of the world, and therefore the two ends, or extremities thereof, muſt anſwer to the north and ſouth poles.

GNOMON, in geometry. If a parallelogram be divided into four leſſer ones by two right lines drawn reſpectively parallel to the ſides thereof, and one of theſe parallelograms be retrenched, or taken away; the remaining three will form a gnomon.

GNOMON, in aſtronomy, a pillar, &c. erected to find meridian altitudes of the ſun and ſtars by its ſhadow.

The method of finding the ſun's meridian altitude by the help of a gnomon was much uſed by the ancients. It muſt be obſerved, that the greater the height of the ſun is, the ſhorter is the ſhadow of a gnomon, and the contrary. In making obſervations for determining the meridian altitudes of the ſun and ſtars, it was uſual to ſet down what proportion the length of the ſhadow bore to the height of the pillar; that is, the height of the pillar being divided into a certain number of equal parts, to ſay how many of theſe parts the length of the ſhadow amounted to at the equinoxes or ſolſtices. The moſt ancient obſervation of this kind, that we meet with, is that made by Pytheas, in the time of Alexander the Great, at Marſeilles, where he found the height of the gnomon was to the meridian ſhadow, at the ſummer ſolſtice, as $213\frac{1}{3}$ to 600; the ſame as Gaſſendus found it to be, by an obſervation made at the ſame place, almoſt 2000 years after, in the year 1636.

A very exact method whereby to obſerve the meridian altitude of the ſun is as follows.—Make a circular perforation in a braſs plate, to tranſmit enough of the ſun's rays to exhibit his image on the floor: fix this plate parallel to the horizon in a high place proper for obſervation: then let fall a plumb-line, whereby to meaſure the height of the perforation above the floor. Take care the floor be perfectly level, and exactly horizontal; and let it be whitened over, to exhibit the ſun more diſtinctly: draw a meridian line thereon, paſſing through the foot of the gnomon, that is, through the point where the center of the plumb-line marks the floor: note the extreme points of the ſun's diameter on the meridian line K and I (plate LXXI. *fig.* 6.) and from each ſubtract a right-line equal to the ſemi-diameter of the aperture, viz. K H on one ſide, and I L on the other: then will H L be the image of the ſun's diameter, which, biſected in B, gives the point on which the rays fall from the center of the ſun.

Now having given the right-line A B, and the altitude of the gnomon, with the angle A, which is right; the angle A B G, or the apparent altitude of the ſun's center, is eaſily found: for aſſuming one of the given ſides A B for radius; A G will be the tangent of the oppoſite angle B. Then ſay, as one leg A B: is to the other A G:: ſo is the whole ſine: to the tangent of the angle B.

GNOMONICS, *Gnomonica*, the art of dialling, or of drawing ſun and moon dials, on any given plane. See the article DIAL.

GNOSTICS, in church-hiſtory, chriſtian heretics ſo called, it being a name which almoſt all the ancient heretics affected to take, to expreſs that new knowledge and extraordinary light to which they made pretenſions; the word gnoſtic ſignifying a learned, or enlightened perſon.

St. Epiphanius aſcribes the origin of the Gnoſtics to Simon Magus, and ſays that they acknowledged two principles, a good and a bad. They ſuppoſed there were eight different heavens, each of which was governed by its particular prince: the prince of the ſeventh heaven, whom they named Sabaoth, created the heavens and the earth, the ſix heavens below him, and a great number of angels. In the eighth heaven they placed their Barbelo, or Barbero, whom they ſometimes called the father and ſometimes the mother of the univerſe. All the Gnoſtics diſtinguiſhed the creator of the univerſe from God, who made himſelf known to men by his Son, whom they acknowledged to be the Chriſt. They denied that the Word was made fleſh; and aſſerted that Jeſus Chriſt was not born of the Virgin Mary, that he had a body only in appearance, and that he did not ſuffer in reality. They neither believed a reſurrection, nor a judgment to come; but imagined that thoſe who had not been inſtructed in their maxims, would return into the world, and paſs into the bodies of hogs and other of the like animals. They had ſeveral apocryphal books, as the Goſpel of St. Philip, the Revelations of Adam, the Goſpel of Perfection, &c.

GOAT, *Capra*, in zoology, a quadruped of the order of the pecora. See the article CAPRA.

GOAT's BEARD, *Tragopogon*, in botany. See the article TRAGOPOGON.

GOAT's EYE, *Ægias*, among ancient phyſicians. See ÆGIAS.

GOAT-SUCKER, *Caprimulgus*, in ornithology, a ſpecies of hirundo. See HIRUNDO.

GOAT's-THORN, the ſame with tragacanth.

GOBELINS, a celebrated manufactory for tapeſtry, eſtabliſhed by Mr. Colbert, at Paris, in 1667. See TAPESTRY.

GOBONE, or GOBONY, in heraldry, the ſame with componed. See COMPONED.

GOD, *Deus*, the Supreme Being, the firſt cauſe or creator of the univerſe, and the only true object of religious worſhip.

The Hebrews called him Jehovah; which name they never pronounced, but uſed inſtead of it the words Adonai, or Elohim. See the articles ADONAI, ELOHIM, and JEHOVAH.

God, ſays Sir Iſaac Newton, is a relative term, and has reſpect to ſervants. It denotes, indeed, an eternal, infinite, abſolutely perfect being: but ſuch a being without dominion, would not be God. The word God frequently ſignifies lord, but every lord is not God. The dominion of a ſpiritual being, or lord, conſtitutes God; true dominion, true God; the ſupreme, ſupreme; pretended, pretended. From ſuch true dominion it follows that the true God is living, intelligent, and powerful; and from his other perfections, that he is ſupreme, or ſupremely perfect. He is eternal and infinite, omnipotent and omniſcient; that is, he endures from eternity to eternity, and is preſent from infinity to infinity. He governs all things that exiſt, and knows all things that are to be known. He is not eternity or infinity, but eternal and infinite. He is not duration and ſpace, but he endures and is preſent: he endures always, and is preſent every where; and by exiſting always and every where, conſtitutes the very things we call duration and ſpace, eternity and infinity. He is omnipreſent, not only virtually, but ſub-

ſubſtantially; for power without ſubſtance cannot ſubſiſt. All things are contained and move in him, but without any mutual paſſion, that is, he ſuffers nothing from the motions of bodies, nor do they undergo any reſiſtance from his omnipreſence.

It is confeſſed, that God exiſts neceſſarily; and by the ſame neceſſity he exiſts always and every where. Hence alſo he muſt be perfectly ſimilar; all eye, all ear, all brain, all arm, all perfection, intelligence, and action; but after a manner not at all corporeal, not at all like men; after a manner altogether unknown to us. He is deſtitute of all body, and bodily ſhape, and therefore cannot be ſeen, heard, or touched; nor ought to be worſhipped under the repreſentation of any thing corporeal. We know him only by his properties, or attributes, by the moſt wiſe and excellent ſtructure of things, and by final cauſes: but we adore and worſhip him only on account of his dominion: for God, ſetting aſide dominion, providence, and final cauſes, is nothing elſe but fate and nature.

The plain argument, ſays Mr. Maclaurin, for the exiſtence of the Deity, obvious to all, and carrying irreſiſtible conviction with it, is from the evident contrivance and fitneſs of things for one another, which we meet with throughout all parts of the univerſe. There is no need of nice or ſubtile reaſonings in this matter; a manifeſt contrivance immediately ſuggeſts a contriver. It ſtrikes us like a ſenſation; and artful reaſonings againſt it may puzzle us, but it is without ſhaking our belief. No perſon, for example, that knows the principles of optics and the ſtructure of the eye, can believe that it was formed without ſkill in that ſcience; or that the ear was formed without the knowledge of ſounds; or that the male and female in animals were not formed for each other, and for continuing the ſpecies. All our accounts of nature are full of inſtances of this kind. The admirable and beautiful ſtructure of things for final cauſes, exalt our idea of the contriver: the unity of deſign ſhews him to be one. The great motions in the ſyſtem, performed with the ſame facility as the leaſt, ſuggeſt his Almighty power, which gave motion to the earth and the celeſtial bodies with equal eaſe as to the minuteſt particles. The ſubtilty of the motions and actions in the internal parts of bodies, ſhews that his influence penetrates the inmoſt receſſes of things, and that he is equally active and preſent every where. The ſimplicity of the laws that prevail in the world, the excellent diſpoſition of things, in order to obtain the beſt ends, and the beauty which adorns the works of nature, far ſuperior to any thing in art, ſuggeſt his conſummate wiſdom. The uſefulneſs of the whole ſcheme, ſo well contrived for the intelligent beings that enjoy it, with the internal diſpoſition and moral ſtructure of thoſe beings themſelves, ſhew his unbounded goodneſs. Theſe are the arguments which are ſufficiently open to the views and capacities of the unlearned; while, at the ſame time, they acquire new ſtrength and luſtre from the diſcoveries of the learned. The Deity's acting and interpoſing in the univerſe, ſhew that he governs, as well as formed it; and the depth of his counſels, even in conducting the material univerſe, of which a great part ſurpaſſes our knowledge, keep up an inward veneration and awe of this great Being, and diſpoſe us to receive what may be otherwiſe revealed to us, concerning him. It has been juſtly obſerved that ſome of the laws of nature now known to us, muſt have eſcaped us, if we had wanted the ſenſe of ſeeing. It may be in his power to beſtow upon us other ſenſes, of which we have at preſent no idea; without which it may be impoſſible for us to know all his works, or to have more adequate ideas of himſelf. In our preſent ſtate, we know enough to be ſatisfied of our dependency upon him, and of the duty we owe to him, the Lord and diſpoſer of all things. He is not the object of ſenſe; his eſſence, and indeed that of all other ſubſtances, is beyond the reach of all our diſcoveries; but his attributes clearly appear in his admirable works. We know, that the higheſt conceptions we are able to form of them, are ſtill beneath his real perfections; but his power and dominion over us, and our duty towards him, are manifeſt.

With reſpect to Chriſtians it will be ſufficient to mention, that they were very early divided in opinion, with regard to the nature and eſſence of the Supreme Being; a great part worſhipping three perſons in the unity of the godhead, while others abſolutely rejected a trinity of perſons, and aſſerted the unity of the Divine nature, both with reſpect to perſon and ſubſtance. See ARIAN and TRINITARIAN.

GODDESS, a heathen deity of the female ſex.

GOD-FATHERS and GOD-MOTHERS, perſons who undertake to anſwer for the future conduct of infants at their baptiſm.

This cuſtom is of great antiquity in the Chriſtian church, and was, in all probability, inſtituted to prevent children from being brought up in idolatry, in caſe their parents ſhould die before they arrived at years of diſcretion.

GOLD, *Aurum*, the ſol and rex metallorum of the chemiſts, is a yellow metal ſcarce at all elaſtic or ſonorous, very ſoft and flexible, the moſt ductile of all metallic bodies. Dr. Halley took one grain of gilt ſilver, of which only one forty-eighth part was gold: this grain was drawn into a wire two ells in length, which examined by a microſcope, appeared every where covered with the gold: a piece of the wire being put into aqua-fortis, the ſilver was eaten out, and a tube of gold remained, which notwithſtanding its extreme thinneſs, was ſtill opake.

Gold is of all natural bodies the moſt ponderous: hence it ſinks into quickſilver, whilſt all other ſubſtances, platina excepted, ſwim on the ſurface. It is upwards of nineteen times heavier than an equal bulk of water: a Paris cubic foot is reckoned to weigh 1368 pounds. From its greater denſity it becomes ſenſibly hotter than other bodies when laid along with them in hot water.

Gold melts in a red heat, much ſooner than copper or iron; though much later than lead or tin. It is of all metals the moſt fixed, or permanent in the fire: an ounce has been kept for two months together, in a glaſs-houſe furnace, which of all furnaces gives the moſt vehement heat, without ſuffering the leaſt diminution of its weight. Homberg relates, that in the focus of Tſchirnhaus's large burning-glaſs, it loſt its fixity; that it ſmoked, diminiſhed in volume, changed into a red earth, and at laſt even vitrified: but as the gold had been placed on a piece of charcoal, the vitreous matter probably proceeded from the aſhes of the coal. Mr. Geoffroy often aſſured me, whilſt we were making experiments together with the ſame burning lens, that no ſuch vitrification had been obſerved, when any thing beſides charcoal was uſed for the ſupport.

Gold diſſolves in a mixture of the nitrous and marine acids, called, from its action on this rex metallorum, aqua-regia: either of theſe acids ſingly have no effect upon it; nor is it acted on by the vitriolic. Boerhaave ſays that ſea-ſalt or ſal-gem are the only menſtrua of gold; and that both theſe ſalts diſſolve it, whether applied in the form of a lixivium or ſpirit: experience affords no foundation for this aſſertion. The ſolution in aqua-regis is of a gold yellow colour, and ſtains the ſkin, wherever it touches, of a fine purpliſh red, which is not eaſily got off.

Singular and unalterable as the properties of gold appear to be, they are eaſily maſtered by chemiſtry. A ſingle grain of tin will deſtroy the ductility of a thouſand grains of gold; rendering the moſt malleable gold not only incapable of being extended, but of bearing the hammer at all. In Kunckel's *Laboratorium Chymicum*, there are proceſſes by which gold may be ſublimed and diſtilled over the helm; and ſurely what ſublimes or diſtils has loſt its fixity. Mercury-ſublimate and ſal-ammoniac volatilize. There is a certain common and well known ſubject, plentifully made uſe of by every body, which robs gold of its luſtre, its colour, and its malleability, and renders it white and brittle: but this ſubſtance, as it might give riſe to abuſes, I forbear to name. Gold melted repeatedly with borax becomes paler and paler on every fuſion; and there are ſundry other ſubſtances, as butter of antimony, zinc, and the ſmoky ſpirit of tin, from which it ſuffers notable alterations. After all theſe changes, however, it is ſtill reducible to its original ſtate; the brittle, the white, the ſublimed, the diſtilled gold, may all be reſtored to the purity

purity and properties of the gold at firſt. The chemiſts have long laboured in the deſtruction of this metal, and allow it to be eaſier to make gold than to deſtroy it; tho' it does not appear that either of theſe problems is entirely beyond the reach of art: for a little gold has in divers experiments been produced; and gold was deſtroyed in the preſence of Mr. Boyle.

Aqua-regia, the proper menſtruum of gold, is commonly prepared by diſſolving one part of ſal-ammoniac in four of aqua-fortis or ſpirit of nitre. Kunckel directs a commodious method of obtaining the exact proportions neceſſary for the ſolution. The gold, either in form of leaves, or granulated, or flatted into thin plates, then made red-hot and cut in ſmall pieces, is to be put into a ſuitable quantity of aqua-fortis, a gentle heat applied, and ſome powdered ſal-ammoniac added gradually, by little and little at a time, till the whole of the gold is diſſolved.

The largeſt quantities of gold are met with in the Spaniſh Weſt-Indies: there are mines of it alſo in ſome parts of Europe, particularly in Hungary and Tranſylvania. It is either imbedded in flinty or other ſtones, or intermingled among the looſe earth; always in its metallic form, though the particles are commonly very ſmall and often indiſtinguiſhable. It is never found in the ſtate of a true ore, unleſs when blended with a large proportion of other metals: the gold ore of Rammelſberg, in Goſlar, holds only a few grains on an hundred weight. Some gold is alſo met with in ſundry rivers, as the Tagus, the Ganges, the Rhine, the Saale, the Niger, the Danube, and many others, commonly in fine duſt, often in flat moleculæ, ſometimes ſuſpended by the water in inviſible atoms, which ſettle upon ſtanding, and are diſtinguiſhed by the name of river or waſh-gold: theſe golden particles doubtleſs proceed from ſome mines or veins of gold; from which the metal has been waſhed out, and carried down by the ſtream. Some have pretended to find perfect gold in vegetables, particularly in the vine-tree; but on examining thoſe gold-like ſpecks or granules, by fire, by quickſilver, or other trials, they ſoon diſcover themſelves to be no gold.

Gold coins and utenſils are not made of pure gold, but have always an alloy of ſilver, or copper, or both together, by which the gold is rendered firmer, harder, and more ſonorous. When gold is perfectly pure, it is called gold of twenty-four carats; the meaning of which is, that in an ounce of the metal all the twenty-four ſcruples are pure gold. If only twenty-three ſcruples are fine gold, and the other ſcruple a baſer metal, it is called gold of twenty-three carats; and in general, the number of carats by which the fineneſs is expreſſed, denotes the number of ſcruples of fine gold in an ounce or twenty-four ſcruples of the mixed. The ancients ſuppoſed the gold of different countries to differ in quality; the Armenian to be the beſt, the Hungarian next to it, and the Rheniſh the worſt. But gold, when perfectly pure, is always one and the ſame, wherever it is to be found; no other differences being obſerved in it than what proceed from an admixture of ſome other metal.

There are different methods of ſeparating gold from admixtures of other metals. If only a baſe metal is mixed with gold, they may be ſeparated by teſting or cupellation with lead; the baſe metal vitrifying with the lead, whilſt the gold remains unhurt.

Silver, which reſiſts the deſtructive power of lead equally with gold itſelf, is ſeparated by acid menſtrua. For this purpoſe, we muſt firſt examine, whether the mixture contains moſt gold, or moſt ſilver: if the gold is found to prevail, the metal is to be flatted into plates, or granulated, and put into a proportionable quantity of aqua-regis, which diſſolves the gold, and leaves the ſilver in the form of powder at the bottom: the ſilver, waſhed and dried, may be melted into a maſs, with the addition of a little tallow, and ſome nitre or borax; and the gold may be recovered from the liquor by precipitation. If on the other hand, the quantity of ſilver is much greater than that of the gold, aqua-fortis is made uſe of, which diſſolves the ſilver, and leaves the gold behind, in form of a black maſs or powder to be waſhed and melted with borax. If the proportions of the two metals are nearly equal, the mixture is melted with ſo much freſh ſilver as will make the whole quantity of ſilver at leaſt three times greater than that of the gold: if the quantity of ſilver is much leſs than this, the beſt aqua-fortis will not be able to extract it from the gold: if much greater, the ſolution or extraction will go on the faſter, but the gold will remain in form of powder, ſome particles of which may be in danger of being loſt: if it is juſt thrice the weight of the gold, the gold retains the form of the original plates: from the gold making one fourth of the compound, the proceſs is commonly called quartation. This method of parting the two metals is more commodious and effectual than that by aqua-regis; aqua-fortis diſſolving the ſilver much ſooner than aqua-regis does the gold; and the former taking up none of the gold along with the ſilver, whereas the latter almoſt always diſſolves a part of the ſilver along with the gold, eſpecially if the aqua-regis is made with an under-proportion of marine acid.

Gold is likewiſe purified from ſilver by acids applied in the form of vapour free from phlegm. Thus applied, they extract ſmall proportions of ſilver as well as large ones; the gold being unable to defend that metal againſt the fumes, as it does againſt the acid in its liquid ſtate. The marine vapours alſo, in this method of application, corrode the ſilver as effectually as the nitrous: the only difference is, that when corroded by the nitrous, ſuch part as may remain in the pores of the gold is eaſily diſſolved and waſhed out by water, whereas with the marine, it forms a concrete not diſſoluble in water.—The method of performing the proceſs is this. Nitre, or common ſalt, (not both at once, for the vapour ariſing from the mixture would diſſolve the gold as well as the ſilver) is mixed with an equal quantity of calcined vitriol, by which its acid is extricated in the fire; and twice its weight of powdered bricks, to prevent the matter from melting and adhering to the ſurface of the metal. The gold impregnated with ſilver, is flatted into plates; cleanſed by ignition from any external unctuoſity that might impede the action of the acid; then ſtratified and every where ſurrounded with the mixture in a crucible or cementing-pot; the veſſel cloſely covered and luted; the fire gradually raiſed to a ſlight red heat, and kept up for twelve, ſixteen, or twenty hours. It is often neceſſary to repeat the cementation; a part of the ſilver being apt to eſcape the action of the fumes, eſpecially when the plates are of conſiderable thickneſs: the metal, after one cementation, muſt be melted and laminated afreſh, before it is committed to another. Theſe kinds of operations were formerly often practiſed; but have now in great meaſure given place to more advantageous and effectual methods of ſeparation. The mixture with ſea-ſalt is commonly called the regal cement, gold being the only metallic body, platina excepted, that is capable of reſiſting it.

The reſiſtance of gold to aqua-fortis affords a ready method of diſtinguiſhing that metal from compoſitions reſembling it in colour. If a line be drawn with the maſs upon any ſmooth ſtone that does not diſſolve in acids, a drop of aqua-fortis will take off the mark left by any of the baſe metals, whilſt that made by gold remains untouched.

If gold contains copper, lead, or other imperfect metallic bodies, along with ſilver, it is purified firſt from the baſe metal by the teſt or cupel, and then ſeparated from the ſilver by quartation.—It is purified alſo from all the metals by fuſion with antimony, which abſorbs or ſcorifies all but gold. Tin is moſt commodiouſly ſeparated by injecting corroſive ſublimate upon the gold in fuſion. Mercury is diſſipated from it by bare ignition.

Gold is cleanſed, from external impurities, by heating it red-hot, and waſhing it with weak aqua-fortis, brine of ſea-ſalt, with tartar, &c. When pale, the colour is heightened, by melting it with copper, and afterwards ſeparating the copper; or by a mixture of verdigriſe and ſal-ammoniac with vitriol or nitre. Some boil the pale gold in a ſolution of theſe ſalts made in vinegar; others moiſten the ſalts with vinegar into the conſiſtence of a paſte, which is ſpread upon the gold, and the metal laid upon burning coals till the mixture is burnt off. The ſprinkling of the ſalts in powder upon the moiſtened gold, practiſed by ſome, does not anſwer ſo well. It is ſaid that a mixture of gold with one third, or even with half its weight of ſilver, acquires, on cementation with verdigriſe,

digriſe, the colour of pure gold. The ſilver however is eaſily diſcovered on the touchſtone, by means of aqua-fortis: if a line be drawn with the compound metal, a little aqua-fortis, applied upon the part, will eat out the ſilver; and the remaining gold will appear ſpecked and diſunited. *Neumann's Chemiſtry.*

GOLD-WIRE, a cylindrical ingot of ſilver, ſuperficially gilt, or covered with gold at the fire, and afterwards drawn ſucceſſively through a great number of little, round holes, of a wire-drawing iron, each leſs than the other, till it be ſometimes no bigger than a hair of the head. See the article WIRE.

It may be obſerved, that before the wire be reduced to this exceſſive fineneſs, it is drawn through above an hundred and forty different holes, and that each time they draw it, it is rubbed afreſh over with new wax, both to facilitate its paſſage, and to prevent the ſilver's appearing through it.

GOLD-WIRE *flatted*, is the former wire flatted between two rollers of poliſhed ſteel, to fit it to be ſpun on a ſtick, or to be uſed flat, as it is without ſpinning, in certain ſtuffs, laces, embroideries, &c. See the article STUFF, &c.

GOLD-THREAD, or SPUN GOLD, is a flatted gold, wrapped or laid over a thread of ſilk, by twiſting it with a wheel and iron bobins.

Manner of forming GOLD-WIRE *and* GOLD THREAD, *both round and flat.* Firſt, an ingot of ſilver, of twenty-four pounds, is forged into a cylinder, of about an inch in diameter: then it is drawn through eight or ten holes, of a large, coarſe wire-drawing iron, both to finiſh the roundneſs and to reduce it to about three-fourths of its former diameter. This done, they file it carefully all over to take off any filth remaining on the forge; then they cut it in the middle; and thus make two equal ingots thereof, each about twenty-ſix inches long, which they draw through ſeveral new holes, to take off any inequalities the file may have left, and to render it as ſmooth and equable as poſſible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking ſome gold leaves, each about four inches ſquare, and weighing twelve grains, they join four, eight, twelve, or ſixteen of theſe, as the wire is intended to be more or leſs gilt; and when they are ſo joined, as only to form a ſingle leaf, they rub the ingots reeking hot with a burniſher. Theſe leaves being thus prepared, they apply over the whole ſurface of the ingot, to the number of ſix, over each other, burniſhing or rubbing them well down with the blood-ſtone, to cloſe and ſmoothe them. When gilt, the ingots are laid anew in a coal fire; and when raiſed to a certain degree of heat, they go over them a ſecond time with the blood-ſtone, both to ſolder the gold more perfectly, and to finiſh the poliſhing. The gilding finiſhed, it remains to draw the ingot into wire.

In order to this, they paſs it through twenty holes of a moderate drawing iron, by which it is brought to the thickneſs of the tag of a lace: from this time the ingot loſes its name, and commences gold wire. Twenty holes more of a leſſer iron leaves it ſmall enough for the leaſt iron; the fineſt holes of which laſt ſcarce exceeding the hair of the head, finiſh the work.

To diſpoſe the wire to be ſpun on ſilk, they paſs it between two rollers of a little mill: theſe rollers are of nicely poliſhed ſteel, and about three inches in diameter. They are ſet very cloſe to each other, and turned by means of a handle faſtened to one of them, which gives motion to the other. The gold wire in paſſing between the two, is rendered quite flat, but without loſing any thing of its gilding, it is rendered ſo exceedingly thin and flexible, that it is eaſily ſpun on ſilk thread, by means of a hand wheel, and ſo wound on a ſpool or bobin.

GOLD-LEAF, or BEATEN GOLD, is gold beaten with a hammer into exceeding thin leaves, ſo that it is computed, that an ounce may be beaten into ſixteen hundred leaves, each three inches ſquare, in which ſtate it takes up more than 159052 times its former ſurface.

This gold they beat on a block of black marble, about a foot ſquare, and uſually raiſed three feet high: they make uſe of three ſorts of hammers, formed like mallets, of poliſhed iron: the firſt, which weighs three or four pounds, ſerves to chaſe, or drive: the ſecond, of eleven or twelve pounds, to cloſe; and the third, which weighs fourteen or fifteen pounds, to ſtretch and finiſh. They alſo make uſe of four moulds of different ſizes, viz. two of vellom, the ſmalleſt whereof conſiſts of forty or fifty leaves, and the larger of two hundred: the other two, conſiſting each of five hundred leaves, are made of bullocks guts well ſcoured, and prepared.

Method of preparing and beating GOLD. They firſt melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickneſs of a ſheet of paper; which done, they cut the plate into little pieces about an inch ſquare, and lay them in the firſt or ſmalleſt mould to begin to ſtretch them: after they have been hammered here a while with the ſmalleſt hammer, they cut each of them into four; and put them into the ſecond mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould, out of which they are taken, divided into four, as before, and laid in the laſt, or finiſhing mould, where they are beaten to the degree of thinneſs required.

The leaves thus finiſhed, they take them out of the mould, and diſpoſe them into little paper books, prepared with a little red bole for the gold to ſtick to; each book ordinarily contains twenty-five gold leaves. There are two ſizes of theſe books; twenty-five leaves of the ſmalleſt only weigh five or ſix grains, and the ſame number of the largeſt, nine or ten grains.

It muſt be obſerved, that gold is beaten more or leſs, according to the kind or quality of the work it is intended for; that for the gold wire-drawers to gild their ingots, is left much thicker than that for gilding the frames of pictures, &c. withal. See GILDING.

GOLD-FINCH, in ornithology, the Engliſh name of a ſpecies of fringilla, with the wings variegated with black, yellow, and white.

GOLD-SIZE. See the article SIZE.

GOLD-SMITH, or as ſome chooſe to expreſs it, ſilver-ſmith, an artiſt who makes veſſels, utenſils, and ornaments in gold and ſilver.

Shell-GOLD, that uſed by the illuminers, and wherewithal we write gold letters. It is made of the pareings of leaf-gold; and even of the leaves themſelves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuſe ſome time in aqua-fortis, they put it in ſhells, where it ſticks. To uſe it they dilute it with gum-water, or ſoap-water.

GOLDEN, ſomething that has a relation to gold, or conſiſts of gold, is valuable, or the like; as,

GOLDEN-BULL. See the article BULL.

GOLDEN-CALF, in Jewiſh antiquity, a figure which the Iſraelites caſt in gold, and ſet up in the wilderneſs to worſhip during Moſes's abſence in the mount, and which that legiſlator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of; as in Exod. xxxii.

GOLDEN-FLEECE, in the ancient mythology, the ſkin, or fleece, of the ram upon which Phryxus and Hella are ſuppoſed to have ſwam over the ſea to Colchis; which being ſacrificed to Jupiter, its fleece was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monſtrous dragon that never ſlept; but was at laſt taken and carried away by Jaſon, and the Argonauts.

GOLDEN-NUMBER, in chronology, a number ſhewing what year of the moon's cycle any given year is. See CYCLE *of the Moon.*

GOLDEN-RULE, in arithmetic, is alſo called the rule of three, and the rule of proportion. See PROPORTION and RULE OF THREE.

GOLPS, in heraldry, are roundles of a purple tincture, called by the French *torteaux*, adding their peculiar colours.

GOMPHOSIS, γόμφωσις, in anatomy, a ſpecies of articulation, wherein one bone is ſet in the other, like a nail or peg; as the teeth within the jaws.

GOMPHRENA, the purple everlaſting flower, in botany, a genus of plants, the flower of which is divided into five parts, and erect: the petals are ſubulated and permanent: the fruit is a thin, roundiſh cruſt, with one

cell, in which are contained a ſingle, large, roundiſh ſeed, with an oblique end. It is a native of both Eaſt and Weſt-Indies; and the flower is uſually of a beautiful purple colour.

GONDOLA, a ſort of barge curiouſly ornamented, and navigated on the canals of Venice. See the article BARGE.

GONORRHOEA, in medicine, an involuntary efflux of the ſeminal juices, and ſome other recrementitious matter.

Authors take notice of three ſpecies of gonorrhœas; the firſt is a ſimple gonorrhœa, or perpetual efflux of the ſeminal juices, without any virulence: the ſecond is a venereal, or virulent gonorrhœa, ſo called, though improperly, from its ſimilitude to the preceding: the third is an involuntary efflux of a viſcid white, or whitiſh fluid from the urethra, in conſequence of a venereal gonorrhœa ill cured, or too frequently repeated.

The firſt ſpecies of this diſorder ariſes from a want of a due tone in the ſolid parts, and by a preternatural relaxation of the veſſels containing the ſeed, and of the parts adjacent to them. See GLEET.

This gonorrhœa is either mild or benign, or of a malignant kind. The latter conſiſts in a diſcharge of matter of various colours, accompanied with heat and exulceration; and in ſcorbutic, or cacochymic patients, as alſo thoſe afflicted with the ſtone, this diſorder is generally attended with a pain in diſcharging the urine, which in ſuch patients is of an acrimonious quality; but in a gonorrhœa of a mild or a benign kind, a whitiſh liquor all of one colour, is diſcharged without pain, heat, or exulceration; and frequently proceeds from a redundance of the ſeminal fluid, ariſing from high living in an unmarried ſtate, or its acrimony in cacochymic, ſcorbutic, or arthritic patients, as well as from the weakneſs of, and want of due tone in, the ſeminal veſſels.

The cure of a benign gonorrhœa is highly difficult; nor can any other reaſon be aſſigned for this diſorder, than that there is a preternatural efflux of impure humours from all parts of the body to thoſe parts infected, which are already too much weakened, and have their tone deſtroyed. Beſides, the parts ſubſervient to generation, which are in this diſorder affected, conſiſt entirely of nerves and nervous coats; and it is not without the greateſt difficulty that the energy of medicines penetrates to them. In the cure, the following intentions are to be purſued. Firſt, the redundance of impure ſerum, if there are any ſuch in the body, is, by means of proper laxatives, to be evacuated and derived from the parts affected. Then the too much relaxed and flaccid parts are to be ſtrengthened by proper corroborating medicines, both of the external and internal kind. The former of theſe intentions is anſwered by ſuch laxatives as operate in a double manner, ſuch as the pilulæ balſamicæ of Becher, which are not only purgative, but highly corroborating. To anſwer the other intention, the following powder muſt be uſed. Take of cuttle-bone, one ounce; of red coral, amber, the ſpecies of hyacinth, and the bark of Caſcarilla, each two drams; make into a powder, one dram of which is to be taken every morning and evening in a decoction of barley, prepared with ſome almonds. At the ſame time the following epithem may be applied to the region of the pubes and perinæum, eſpecially during the night-time. Take of herbs, baum, mint, and baſil; of the leaves of red roſes, and balauſtins, each one handful; of pomegranate-bark, cloves, nutmegs, cardamoms, and maſtich, each half an ounce; mix together, and put into a ſmall bag to be boiled in red French wine. Theſe meaſures are to be ſeconded by an accurate regimen, being chiefly ſuch as is preſcribed below for the virulent gonorrhœa. In the cure of a malignant gonorrhœa, regard is to be had to the conſtitution of the patient: when he is hot, and of a delicate conſtitution, he ought, eſpecially in the beginning of the diſtemper, to abſtain from hot ſubſtances, purgatives, ſudorifics, diuretics, &c. The following preparation may be frequently exhibited in this diſorder. Take of mint, three handfuls; of Venice turpentine, one ounce; of Peruvian balſam, half an ounce: diſtil with three pints of Rheniſh wine. The doſe is from one to two ounces: and the following may be uſed as a ſucceſdaneum. Take of roſe-water, and rectified ſpirit of wine, each half a pint; and of the balſam of life, fifty drops. Mix all together.

A virulent gonorrhœa, or clap, being the ſecond ſpecies of this diſorder, proceeds from impure coition with an infected perſon.

This diſtemper begins, and makes its progreſs, in the following manner.

The patient, ſooner or later, according as the perſon with whom he has had converſation, was more or leſs infected, and according to his conſtitution, by which he may be more or leſs diſpoſed to receive the infection, is firſt ſeized with an unuſual pain in the genitals; and a kind of ſenſation like a rotation of his teſticles. Afterwards, if the prepuce conſtantly covers his glands, there appears an eruption, or puſtule, which, by its ſize, colour, and figure, reſembles a ſpot of the meaſles. Preſently after appears a weeping matter like ſemen, which daily changes colour, and becomes more purulent, and more yellow, till at length, if the diſorder be highly virulent, it aſſumes a greeniſh hue, or appears like a thin ſanious matter, mixed with blood. The puſtule at length becomes an ulcer, called a ſhanker. See SHANKER.

Thoſe whoſe glans is uncovered, ſeldom have ſuch a puſtule, and are leſs liable to imbibe the infection. The running brings on a heat, or ſmarting in making water, which is moſt violent when it is over, for then it ſeems to burn the whole duct of the urethra.

Another ſymptom is the cordee, or contraction of the frænum, by which the penis is bent downwards. There is likewiſe, when the penis is erected, great pain, as if compreſſed tranſverſely with a ſtrong hand. This chiefly happens in the night, when the patient is warm in bed: ſometimes the urethra being eaten, and excoriated with long running of acrimonious pus, nature breeds a ſoft ſpungy fleſh, to ſupply the defect, which daily increaſing, forms caruncles, or carnoſities ſo far as to plug up the urinary paſſage, and ſtop up the urine. However, the little adjoining ulcers continue to pour forth a kind of an ichor. It alſo happens, through ſome violent motion, or the ill-timed uſe of aſtringents, that the ſanies, which ſhould be carried off by the gonorrhœa, is tranſlated to the ſcrotum, and cauſes one or both of the teſticles to ſwell, and inflame with intolerable pain: the running at the ſame time decreaſing, while the ſcalding of the urine is as great as ever.

To theſe ſymptoms may be added the phimoſis, and the paraphimoſis. There are alſo ſometimes watery bladders, called cryſtallines, and at length buboes of the glands in the groin. See PHIMOSIS, PARAPHIMOSIS, BUBO, and POX.

Women are not ſo ſubject to ſuch a variety of ſymptoms as men; their chief complaint being a difficulty of urine, and a running; however, they are liable to ſhankers and venereal warts, as well within as on the outward parts of the labia pudendi; as alſo to buboes in the groin: as for the coarctation of the ſphincter vaginæ, paſſing as it were the external orifice, this is not a phimoſis, though by ſome improperly ſo called.

This diſorder proceeding from an infection of a malignant gonorrhœa, or the lues venerea, is firſt conveyed to the genitals, and afterwards through the pores to the lymph, or ſeminal liquor; the due craſis and natural mixture of which it deſtroys, by inducing partly a cauſtic and corroding, and partly a putrid ſtate thereof; hence ariſe the pains, the heats, the tumours, the inflammations, and the exulcerations of the genitals: for at firſt the glans only is infected whilſt in coition, the poiſon inſinuating itſelf into the pores; after which, it ſoon proceeds to the glands of the urethra, then to the proſtate, and afterwards to the veſiculæ ſeminales. The regimen, during the time of the cure, according to Boerhaave, requires the patient to abſtain from all oily food; and he muſt alſo avoid every thing, which by its acrimonious quality ſtimulates to venery; ſuch as ſpices, bulbous roots, fleſh, eggs, fiſh, and fermented liquors: for as the inflation of the penis retards the cure, it is of the utmoſt conſequence to be avoided; as are alſo every thing elſe that inflames the fancy, or provokes to venery, as amorous dalliance with women, &c. Water and whey are the beſt drinks; and ſeeds and ſummer fruits the beſt aliment. All poſſible care muſt be taken that cold never reach

reach the penis, and that it be kept always moiſt, leſt the pores contracting repel the flux of matter. An emollient and ſomewhat antiſeptic cataplaſm will be beneficial. In the cure, Sydenham's method of purging the patient till the ſymptoms were abated is now juſtly laid aſide. Turner's laſt method, which he made uſe of himſelf, is as follows: Take two drachms of quickſilver; one drachm of gum guaiacum; and beat them, together with a little ſpirit of lemon, till the globules of the mercury diſappear: afterwards add half a drachm of the pills of colocynth with aloes: beat it into a maſs; of which make up twenty-four pills. Two of theſe pills containing half a ſcruple of the mercury, may be taken night and morning; or according to the operation, one only for a week or ten days, unleſs the patient complains of his gums, or a ſore mouth; for then the mercury muſt be left out.

If the cordee does not remit, a ſcruple of ſal prunella may be taken, with as much fine ſugar between whiles, in a draught of the following apozem: Take of mercurial water two pounds; of the ſolution of gum arabic, and ſyrup of marſh-mallows, of each one ounce; make it into an apozem, or decoction. The mercurial water is common river-water, in two quarts of which four ounces of quickſilver have been boiled to a quart. The patient may drink of the apozem through the whole courſe.

And now, as there is occaſion, the pills are continued for a week, or ten days more, but at night only; and in the morning is given the quantity of a nutmeg of the following electuary: Take virgin-honey, an ounce and a half; balſam of capivi, ſix drachms; powder of the root of jalap, and ſal prunella, of each one drachm, which make into an electuary. The patient muſt drink a draught of the apozem as well after the electuary as after the pill.

There is no danger of the running being ſtopt while his body is kept open by theſe means; but when the quantity grows leſs, and the colour whiter, and feels more tenacious, the pill is laid aſide, and the electuary kept to ſome days longer, night and morning. If it purges too much, the jalap is left out, and the rhubarb ſubſtituted inſtead thereof. When it proves tedious, boiled turpentine is given by way of farther agglutinating, and drying the gleet.

When the cordee and dyſury are very ſtubborn, or the running more virulent than ordinary, the genitals are to be ſmeared every night quite up to the groin, with the weaker blue ointment, and the pill without the quickſilver is given early in the morning in a large doſe, or a draught of the infuſion of ſenna. This method will ſucceed in three weeks, or a month's time, if the patient is governable.

In the place of mercurials given internally, Aſtruc directs the uſe of crude quickſilver, as in the common unction, to be rubbed upon the parts, as about the body of the penis, eſpecially under the urethra, to the perinæum, and ſo up to the pubes and teſticles, by which the mercury, inſinuating itſelf through the pores into the lymphatic veſſels, is inſtantly conveyed into the glandules, and ſubdues the poiſon lodged therein, taking away all the ſymptoms without any diſturbance to the primæ viæ, the ſtomach and guts.

If there is no diſcharge from the penis of any virulent matter, it is called the gonorrhœa ſicca, or dry clap; the ſymptoms of which are a dyſury, or difficulty of making water, and after, from the increaſe of the inflammation and tumefaction, an iſchury, or total ſuppreſſion of urine.

In the cure of the dry clap, Aſtruc adviſes plentiful bleeding in the beginning, to take off the tenſion, and to abate the inflammation; as alſo emollient decoctions of mallows, linſeed, &c. in milk, to foment the parts: but perhaps it might be better to make a poultice of theſe ingredients, after Boerhaave's method, to lay to the parts affected; or, which is beſt of all, to uſe them one after the other.

Aſtruc adviſes alſo lenient clyſters, cooling emulſions, and ptiſans, with ſal prunella and anodynes, between whiles. During the continuance of the inflammation, no mercurials muſt be uſed, and if the ſymptoms increaſe, threatening an abſceſs in the perinæum, it is to be forwarded as much as poſſible, by ſuppurative poultices, and the matter diſcharged.

When the gonorrhœa has continued a long while, or long enough for the poiſonous matter to make its way into the blood; or by aſtringents given unſeaſonably it cannot make its exit; then the patient is infected with the pox.

The third ſpecies of this diſorder requires the very ſame treatment with the ſimple and virulent: but here the leaſt time muſt not be loſt; the affected part muſt be kept in a conſtant ſtate of laxity, by the moſt emollient applications; and the contagious matter muſt with all poſſible expedition be drawn out: for the whole cure depends upon the total diſcharge of the infectious matter, together with the pus, which it has introduced; and if this taſk is not performed, a pox is greatly to be apprehended. Wherefore, if this diſeaſe continues but for a little time, recourſe muſt be had to all the ſeverities of a ſalivation. For though ſalivating does not at all cure either of the two former kinds of gonorrhœa, this ſpecies of the diſeaſe, having its ſeat in the glandulæ Cowperianæ of the urethra, ſo that the pus diſcharges itſelf by their excretory duct into the urinary duct, is much more ſuſceptible of the power of mercury.

GOOD, in general, whatever is apt to cauſe or increaſe pleaſure, or diminiſh pain in us; or, which amounts to the ſame, whatever is able to procure, or preſerve to us the poſſeſſion of agreeable ſenſations, and remove thoſe of an oppoſite nature.

Metaphyſical GOOD, the ſame with perfection. See PERFECTION.

Moral GOOD denotes the right conduct of the ſeveral ſenſes and paſſions, or their juſt proportion and accommodation to their reſpective objects and relations.

GOOD BEHAVIOUR, in law, an exact carriage and behaviour to the king and his people.

GOOGINGS, in ſhip-building, certain plates of iron bolted to the ſtern-poſt of a ſhip, to receive and keep ſteady the rudder.

There are four or five of them on the ſtern-poſt, having a large hole in each, into which certain ſpindles, called pintles, are introduced, upon which the rudder reſts, and turns as upon an axis. See the article RUDDER.

GOOSE, *Anſer*, in ornithology, a well-known bird of the anas-kind, with the back of a greyiſh brown colour, the belly and edges of the wing-feathers white.

Geeſe are fowls of great profit, both for food, for their feathers, and for their greaſe. For the gathering of their feathers, ſome authors adviſe their being pulled twice a year, viz. in March and Auguſt; yet this is certainly an unprofitable as well as a cruel practice; for the gooſe on being incapable of flight, eaſily falls a prey to the fox, and other ravenous creatures, and by uncloathing her, you occaſion her getting cold, which ſuddenly kills her. 'Tis therefore, moſt adviſeable to ſtay till moulting time, or till you kill her, and then all her feathers may be made uſe of at pleaſure.

GOOSE-BERRY, *Groſſularia*, or *Ribes*, in botany. See the article RIBES.

The beſt way of raiſing theſe uſeful buſhes is by cuttings, obſerving always to take the handſomeſt ſhoots, and that from branches that bear moſt fruit. Theſe are to be planted in February.

There are a great many ſorts of gooſe-berry, among which the white Holland kind is the faireſt, and beſt bearer of all others; the berries being large, tranſparent, and well taſted. The Engliſh yellow gooſe-berry is known every where, and fitteſt for culinary uſes while green. The hedge-hog gooſe-berry is large, well-taſted, and extremely hairy. There is alſo a ſort of green gooſe-berry, that is a very pleaſant fruit.

Gooſe-berries taken in ſeaſon, produce a delicious wine, very proper for ſummer repaſts. Alſo, if thoroughly preſſed, with an addition of water, and well fermented, they yield in diſtillation the beſt brandy of any of our fruits, and little inferior to French brandy.

GOOSE-NECK, among ſailors, a ſort of hook fixed in the inner end of a boom, or pole, to extend the bottom of ſome of the ſails of a ſhip, particularly the main boom of a brig or ſloop, and the lower-ſtudding-ſail booms of ſhips and larger veſſels. See the article BOOM.

The

The gooſe neck is hooked in a ring or eye-bolt of iron, and may be occaſionally unhooked at pleaſure.

GOOSE-WINGS *of a Sail*, the clues, or lower corners, of a ſhip's main-ſail or fore ſail, when the middle part is tied up or furled to the yard.

The gooſe-wings are only uſed in a great ſtorm to ſcud under, when the ſail at large, or even reefed, would be too much for the ſhip to carry at ſuch a time.

GOR-COCK, a bird, otherwiſe called a moor-cock. See MOOR-COCK.

GORDIAN KNOT, in antiquity, a knot made in the leathers or harneſs of the chariot of Gordias, king of Phrygia, ſo very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he who untied this knot, ſhould be maſter of Aſia. Alexander having undertaken it, was unable to accompliſh it, when fearing leſt his not untying it ſhould be deemed an ill augury, and prove a check in the way of his conqueſts, he cut it aſunder with his ſword, and thus either accompliſhed or eluded the oracle.

GORE, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure conſiſting of two arch lines drawn one from the ſiniſter chief, and the other from the ſiniſter baſe, both meeting in an acute angle in the middle of the feſs point.

GORE, in law, ſignifies a narrow ſlip of ground.

GORGE, *Gula*, in architecture, the narroweſt part of the Tuſcan and Doric capitals, lying between the aſtragal, above the ſhaft of the pillar and the annulets. See TUSCAN and DORIC.

It is alſo uſed for a concave moulding, larger, but not ſo deep as a ſcotia, which ſerves for compartments, &c. See the article COMPARTMENT.

GORGE, in fortification, the entrance of the platform of any work.

In all the out-works, the gorge is the interval betwixt the wings on the ſide of the great ditch, as the gorge of a ravelin, half-moon, &c. Theſe, it is to be obſerved, are all deſtitute of parapets; becauſe, if there were any, the beſiegers, having taken poſſeſſion of the work, might uſe it to defend themſelves from the ſhot of the place; which is the reaſon that they are only fortified with paliſadoes, to prevent a ſurprize.

The gorge of a baſtion is nothing elſe but the prolongation of the curtins from their angle with the flanks, to the center of the baſtion where they meet. When the baſtion is flat, the gorge is a right line, which terminates the diſtance between the two flanks. See the articles BASTION and FORTIFICATION.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a ſwan, &c. and in that caſe it is ſaid, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is alſo uſed when the gorge, or neck of a peacock, ſwan, or the like bird, is of a different colour or metal from the reſt.

GORGED, among farriers, &c. ſignifies the ſame as ſwelled; in which ſenſe they ſay, the legs of a horſe are gorged; the paſtern joint is gorged; you muſt walk him out to diſgorge his ſhoulder.

GORGERIN, in architecture, the ſame with gorge. See the article GORGE.

GORGONS, in antiquity, a warlike female nation of Lybia, in Africa, who had frequent quarrels with another nation of the ſame ſex, called Amazons.

GOSHAWK, the Engliſh name of the yellow-legged falcon, with a brown back, and a white variegated breaſt.

GOSPEL, the hiſtory of the life, actions, death, reſurrection, aſcenſion, and doctrine of Jeſus Chriſt.

The word is Saxon, and of the ſame import with the Latin term *evangelium*, or the Greek ευαγγελιον, which ſignifies glad tidings, or good news; the hiſtory of our bleſſed Saviour being the beſt news ever publiſhed to mankind.

This hiſtory is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John; who from thence are called evangeliſts. The Chriſtian church never acknowledged any more than theſe four goſpels as canonical; notwithſtanding which, ſeveral apocryphal goſpels are handed down to us, and others are entirely loſt.

The ancient fathers endeavoured to find out divers myſteries in there being but four genuine canonical goſpels. St. Jerom, in particular, ſays, that as there are four parts of the world, and four principal winds, it was alſo proper there ſhould be four goſpels in the church, as four columns to ſupport it, and four breathings of life to render it immortal. They thought they found the figure of the four evangeliſts in the beginning of the prophecy of Ezekiel, and in the ninth chapter of the Revelations, where mention is made of four living creatures, the firſt having the face of a man; the ſecond of a lion; the third of an ox; and the fourth of an eagle; and for this reaſon the evangeliſts are uſually painted with theſe ſymbols.

GOSSYPIUM, cotton, in botany. See the article COTTON.

GOTHIC, in general, whatever has any relation to the Goths: thus, we ſay, Gothic cuſtoms, Gothic architecture, &c. See the article ARCHITECTURE.

Gothic architecture is far removed from the manner and proportions of the antique; having its ornaments wild and chimerical, and its profiles incorrect: however, it is frequently found very ſtrong, and appears very rich and pompous, as may be ſeen in ſeveral of our Engliſh cathedrals. This manner of building was, originally, very heavy and coarſe; but is ſince run into the oppoſite extreme, being ſlender, rich, and delicate to a fault. In the Gothic architecture we ſee high vaults raiſed on ſlender pillars; and every thing crowded with windows, roſes, croſſes, figures, &c.

GOVERNMENT, in general, is the polity of a ſtate, or an orderly power conſtituted for the public good.

GOVERNMENT is alſo a poſt or office which gives a perſon the power or right to govern or rule over a place, a city or province, either ſupremely or by deputation.

GOVERNMENT is alſo uſed for the city, country, or place to which the power of governing is extended.

GOVERNMENT, in grammar, a part of conſtruction uſually called regimen.

GOUGE, an inſtrument or tool uſed by divers artificers; being a ſort of round hollow chiſſel, for cutting holes, channels, grooves, &c. either in wood or ſtone. See the article JOINERY.

GOURD, *Cucurbita*, in botany. See the article CUCURBITA.

GOUT, *Arthritis*, in medicine, as defined by Boerhaave, a very painful diſeaſe, whoſe ſeat is in the joints and ligaments of the feet, and whoſe principal times of invaſion are the ſpring and autumn.

The curative intention, according to Wintringham, requires, firſt, that the primæ viæ be ſet free from a load of indigeſted crudities, and the viſcera be reſtored to their priſtine vigour; ſecondly, that the fluid ſtagnating in and ſtuffing up the ſmaller veſſels, may be expelled the body, and a free paſſage through the contracted veſſels be reſtored.

The firſt intention may be anſwered by vomits and gentle cathartics repeated as occaſion requires; by bitters, aromatics, antiſcorbutic medicines; by alkaline fixed ſalts, taken in ſmall quantities for a long time; by aliments and drinks that are nouriſhing, light, eaſy of digeſtion, quickly aſſimilated, and taken in due quantity; by powerful exerciſe often repeated, and long continued; and eſpecially by riding in a dry, ſerene, pure air; by frictions; by motion of the affected parts; by going to ſleep at early hours.

The ſecond intention may be anſwered partly by the preceding, as well as by procuring gentle ſweats; by bathing in natural and artificial baths; by ſweating in a bagnio; or by the uſe of volatile ſalts, and copious drinking of attenuating liquors, actually hot, in the morning while in bed, in order to procure a ſweat; as alſo by mercurial purges, taking a large quantity of diluents after them; by frictions of the whole body, eſpecially the parts affected, with hot, dry linen-cloths, till a redneſs appear; by cold baths; and the like.

To abate the exceſſive pain in the part affected, Boerhaave ſays, that if there be an abſolute neceſſity, opiates may

may be given internally, and the patient may drink plentifully of hot whey, or any other liquor of the like nature. Externally emollients and anodynes may be uſed, laid on pretty hot; or the part affected may be beat with nettles; or it may be anointed with terebinthinated balſam of ſulphur; or tow may be burnt thereon.

GOUT-WORT, in botany, a term ſometimes uſed for angelica. See ANGELICA.

GOUTY-LAND, among farmers, denotes a mooriſh, cold, and black ſoil, abounding with ſprings.

In Staffordſhire this ſort of land is ordered much in the ſame manner as heathy land, only that it is uſually burnt deeper. It bears little but oats, white oats upon the gouty, and black oats upon the black cold land.

The turf of theſe grounds burnt, and carried upon rye or barley-lands, is eſteemed a better improvement than dung. See the article HEATHY LAND.

GRACE, *Gratia*, among divines, ſignifies any unmerited gift which God beſtows on mankind.

Divines diſtinguiſh grace into habitual and actual: the firſt reſides ſtatedly in us, is fixed in the ſoul, and remains till it is expunged by ſome grievous wilful ſin. This is alſo called juſtifying grace, as it makes us appear innocent and righteous in the ſight of God; and ſanctifying grace, as it makes us holy and devoted to God. Actual grace is that which God gives us for the ſpecial performance of ſome particular good thing, as to convert us, to enable us to reſiſt a particular temptation, &c.

Grace is alſo divided into natural and ſupernatural: the natural including the gifts of being, life, of rational faculties, and immortal ſoul, &c. and the ſupernatural is conſidered as a gift conferred on intelligent beings in order to their ſalvation.

Act of GRACE, an act of parliament for a general and free pardon, and for ſetting at liberty inſolvent debtors.

Days of GRACE, in commerce. See DAY.

GRACES, in heathen mythology, three goddeſſes, whoſe names were Aglia, Thalia, and Euphroſyne; that is, ſhining, flouriſhing, and gay; or according to ſome authors, Paſithea, Euphroſyne, and Ægiale. Some make them the daughters of Jupiter and Eurynome, or Eunomia, the daughter of Oceanus; but the moſt common opinion is, that they were the daughters of Bacchus and Venus.

They are ſometimes repreſented dreſſed, but more frequently naked, to ſhew, perhaps, that whatever is truly graceful, is ſo in itſelf, without the aid of exterior ornaments. They preſided over mutual kindneſs and acknowledgment; beſtowed liberality, eloquence, and wiſdom, together with a good grace, gaiety of diſpoſition, and eaſineſs of manners.

GRACILIS, in anatomy, a muſcle of the leg, ſo called from its ſlenderneſs: it ariſes from the ſynchondroſis of the os pubis.

GRADATION, in general, the aſcending ſtep by ſtep, or in a regular and uniform manner.

GRADATION, in architecture, a flight of ſteps, particularly aſcending from the cloiſter to the choir in churches.

It alſo denotes an artful diſpoſition of ſeveral parts, as were by ſteps and degrees, after the manner of an amphitheatre; ſo that thoſe placed before, are rather ſerviceable than the contrary, to thoſe behind.

GRADATION, in painting, a gradual and inſenſible change of colour, by the diminution of the teints and ſhades.

GRADATION, in rhetoric, the ſame with climax. See the article CLIMAX.

GRAFT, or GRAFF, in gardening, a cion or ſhoot of a tree inſerted into another, ſo as to make it yield fruit of the ſame nature with that of the tree from whence the graft was taken.

In the choice of grafts, the following directions ſhould be carefully obſerved: 1ſt. That they are ſhoots of the former year. 2dly. That they are taken from healthy fruitful trees. And, 3dly. That you prefer thoſe grafts which are taken from the lateral or horizontal branches, to thoſe taken from the perpendicular ſhoots. Theſe grafts ſhould be cut off from the trees before the buds begin to ſwell, which is generally three weeks or a month before the ſeaſon for grafting; therefore when they are cut off, they ſhould be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying: if a ſmall joint of the former year's wood be cut off with the cion, it will preſerve it the better; and when it is grafted, this may be cut off; for the grafts muſt be cut to a proper length before they are inſerted into the ſtocks; but till then, the ſhoots ſhould remain their full length, as they were taken from the tree, which will preſerve them better from ſtriking. If theſe grafts are to be carried to a conſiderable diſtance, it will be proper to put their cut ends into a lump of clay, and to wrap them up in moſs, which will preſerve them freſh for a month or longer: but theſe ſhould be cut off earlier from the trees, than thoſe which are to be grafted near the place where the trees are growing. For the choice of ſtocks for grafting, ſee the article STOCK.

GRAFTING, or ENGRAFTING, is the taking a ſhoot from one tree, and inſerting it into another, in ſuch a manner that both may unite and form one tree.

The reaſon for grafting is, that as all good fruits have been accidentally obtained from ſeeds, ſo theſe when ſown will often degenerate, and produce ſuch fruit as are not worth cultivating: but when the ſhoots, cions, or grafts, are taken from ſuch trees as yield good fruit, theſe will never vary from their kind, whatever be the ſtock, or tree, on which they are grafted.

The moſt proper ſeaſon for grafting is in the ſpring, juſt before the riſing of the ſap, or at leaſt before it riſes in any great quantity: but the weather muſt be neither froſty nor wet; nor ſhould the wind blow very bleak or ſtrong when this operation is performed: for on theſe circumſtances, and upon the exact joining of the inner bark of the cion with the inner bark of the ſtock, ſo that the ſap which flows between the bark and the wood may be communicated from the one to the other, the ſucceſs of grafting chiefly depends.

The implements neceſſary for grafting are, a fine ſmall hand-ſaw to cut off the heads of large ſtocks; a good ſtrong knife with a thick back to make cleſts in the ſtocks; a ſharp pen-knife to cut the grafts; a grafting chiſſel, and a ſmall mallet to pare away the wood; baſs, or woollen yarn to tie the grafts with; and a quantity of clay, or cement, properly prepared, to lay over the inciſions, in order to prevent their bleeding, and keep out the air.

The method of preparing the clay intended for this purpoſe, is to mix thoroughly together a quantity of ſtrong, fat loom, ſome new ſtone-horſe dung broken into ſmall bits, a little tanners hair, or ſtraw, cut very ſmall, with a little ſalt, and as much water as will make the whole of the conſiſtence of pretty ſtiff mortar.

The cement or compoſition which ſome have of late uſed, and which has been found to anſwer the deſign of keeping out the air better than the above clay, is made of turpentine, bees wax, and roſin, melted together. This compoſition, when of a proper conſiſtence, is laid about a quarter of an inch thick, upon the cut part of the ſtock round the graft; and has this farther advantage over the clay, that there is no danger of its being hurt by froſt; for cold hardens it; and when the heat of ſummer comes on, by which time it is no longer wanted on the tree, it will melt and fall off without any trouble.

Among the ſeveral methods of grafting hitherto known, the following are moſt approved, and generally practiſed.

Cleft-GRAFTING, called alſo STOCK, or SLIT-GRAFTING.—This is uſed chiefly for middle ſized ſtocks, from one to two inches in diameter. The ſeaſon for it is in the months of February and March; and the method, as now practiſed, is thus.

The head of the ſtock being ſawn, or cut off, with a ſlope, ſmooth and clean; a perpendicular cleft is made therein, about two inches deep, with a ſtrong knife, or chiſſel, from the top of the ſlope, as near to the pith as may be without touching it. In this cleft, the grafting chiſſel, or a wedge, is put to keep it open. The graft, or cion, is prepared by cutting it aſlope, in form of a wedge, to ſuit the cleft; only leaving a ſmall ſhoulder on each ſide; and when cut, it is to be placed exactly in the cleft, ſo as that the inner bark of the cion may aptly, and cloſely, join to the inner part of the bark, or rind of the

ſtock; in the dextrous performance of which, the chief part of the art of grafting conſiſts. That ſide of the cion, which is to be placed outward, at the part where it is cut wedge-wiſe and inſerted into the cleft of the ſtock, ſhould be much thicker than the other ſide, the better to facilitate the exact joining of its rind to that of the ſtock; for if theſe two do not unite, the graft will not ſucceed. The rind of the ſtock choſen for this way of grafting ſhould therefore not be too thick; becauſe it will then be the leſs manageable. If the cleft pinch too tight, a ſmall wedge may be left in it to bear the ſtreſs. As ſoon as the graft is properly fixed, the cleft ſhould be cloſely covered over with clay, or, which ſome think better, with moſs, or the freſh bark of a tree bound on with ozier.

When this method, which is the moſt ancient, and moſt common, manner of grafting, is uſed to ſtocks that are not ſtrong, a ligature of baſs ſhould be made around the ſtock, to prevent the opening of its ſlit; and the whole ſhould then be clayed over, or covered with the cement before deſcribed, to hinder the air from penetrating into the ſlit, ſo as to deſtroy the graft, only two eyes of which ſhould here be left above the clay, for ſhooting.

The ſtraighteſt and ſmootheſt part of the ſtock ſhould always be preferred for grafting, in whatever way this operation is performed.

GRAFTING *in the Rind*, or SHOULDER-GRAFTING, likewiſe called *ſlicing* and *packing*, to diſtinguiſh it from *grafting in the bark*, which will next be ſpoken of, is performed in the following manner, about the latter end of March, or the beginning of April, on more ſlender ſtocks than thoſe which are commonly uſed for cleft-grafting.

The top of the ſtock is cut off in a ſmooth, ſtraight place: then the cion, or graft, is prepared by cutting it on one ſide from the joint, or ſeam, down ſlope-wiſe, making the ſlope about an inch, or an inch and an half long; and obſerving it is bent, ſo that the cion may ſtand nearly upright when it is fixed to the ſtock. At the top of the ſlope, a ſhoulder is made, whereby it is to reſt on the crown of the ſtock. The whole ſlope muſt be plain and ſmooth, that it may lie even to the ſide of the ſtock. The length of the cion uſed here may be about four inches from the ſhoulder, for a ſtandard tree; but for a dwarf, or wall tree, it may be ſix inches. When the cion is prepared, the outſide of its ſloped end, from the ſhoulder downward, is applied to the weſt, or ſouth-weſt ſide of the ſtock, and its length and breadth meaſured thereon; which done, the bark of the ſtock (but not any of its wood) is cut away to thoſe dimenſions, that the cut part of the cion may be fitted in as exactly as poſſible. In doing this, regard muſt be had to the bigneſs of the ſtock, and the thickneſs of its bark, in order to proportion thereto the length and breadth of the cut part of the cion; otherwiſe the paſſages of the ſap in the ſtock and cion will not meet, and the cion will then of courſe periſh. When the cut part of the cion is exactly fitted to, and laid on that of the ſtock, they are bound together with woollen yarn, and covered with clay an inch above, and as far below, the head of the ſtock; working it round the cion, till it become ſharp at top, that the rain may run down it.

This method has ſeveral advantages over the former. Among theſe are, that the wound heals up ſooner, and that, in the mean time, it is in leſs danger from the weather; that it does leſs injury to the ſtocks and grafts, by avoiding all ſevere ſplittings and pinchings; that the bark is more eaſily placed in the paſſage of the ſap here, than in the cleft; that the graft thrives and ſhoots with greater vigour, and bears ſooner in this way than in that; and that it is practicable on ſmaller ſtocks than the other, which muſt have a good body, and conſiſtence, before they can bear cleaving.

GRAFTING *in the Bark* is performed thus. Prepare the ſtock and cion as for grafting in the rind, both as to time and manner; but, inſtead of cutting out the bark of the ſtock, ſlit it down, on the ſouth-weſt ſide, from the top, almoſt as long as the ſloped part of the cion, and at the top of the ſlit looſen the bark, with the point of your knife. Then thruſt an inſtrument, made of very hard wood, ivory, ſilver, or the like, and formed at the end like the ſlope-end of the cion, but much leſs, down, between the bark and wood, to make room for the cion; which being put in, the bark is to be ſo managed, as that it may cloſe exactly to the ſtock and edges of the cion, and the whole is then to be bound up, and covered as before.

Whip-GRAFTING, or *Tongue*-GRAFTING, is proper for ſmall ſtocks, from an inch diameter to a quarter of an inch, or even leſs. Mr. Worlidge, Mr. London, Mr. Miller, and others, ſpeak of it as the moſt effectual way of any, and that which is moſt in uſe, becauſe the cion covers the ſtock much ſooner in this method than in any other; for here the cion and the ſtock muſt always be of the ſame thickneſs. There are three ways of performing it, and all of them may be practiſed ſomewhat later than either of the foregoing.

The firſt is, to ſlope the cion off a full inch, or more; then to do the ſame to the ſtock; and afterwards to tie the one to the other, with baſs or yarn, ſo as to join them cloſely at every part, but particularly at the rind; and then to cover the joint carefully with well tempered clay. The baſs uſed for this, or for any other binding, ſhould be taken from a ſound mat, and be ſoaked in water for ſome hours, to increaſe its ſtrength, and render it the more pliable.

The ſecond way is, to make a ſhoulder in the graft, and, the head of the ſtock being cut off and ſmoothed, to join it as in grafting in the rind.

The third method, which is an improvement of the laſt, is properly named tipping or tonguing. This is done by cutting the ſtock off ſlanting, as before, and leaving at its upper ſide a thin piece, or tongue, as it is called, of the wood, pared away like the lower end of a cion. The cion is then ſloped, and tongued, in the ſame manner as the ſtock, and a ſlit is made in each of them, downward in the ſtock, and upward in the graft, on the ſide oppoſite to the tongue, ſo that each may receive the tongue of the other. The cion is then joined to the ſtock, as cloſely as can be, particularly at the bark; a ligature is made round them with baſs or woollen yarn, and the engrafted part is well covered with clay or cement.

Side-GRAFTING. In this, the cion is prepared as in whip-grafting; but the head of the ſtock is not cut off at the time of performing the operation. Inſtead of that, ſo much of the bark as the cion will cover is pared off from the weſt-ſide of the ſtock; then both the cion and the ſtock are ſlit in the laſt mentioned manner of whip-grafting, and they are bound together, and cloſed up with clay. At the year's end, the top of the ſtock is cut off at the grafted place, ſlopewiſe; and the wound is covered with clay or cement.

Scutcheon-GRAFTING is another method of grafting in the rind, by ſlitting the bark of the ſtock in form of the capital letter T, looſening it with the point of a knife, and inſerting a cion prepared as above. This is practiſed in June, July, and Auguſt; eſpecially if bark does not part eaſily from the ſtock; and in caſe of failure, it is properly ſupplied by cleft-grafting, in the enſuing month of February or March.

Crown-GRAFTING is only practiſed in the larger trees, which are capable of receiving a number of grafts, and are too big to be cloven: for theſe, the head or main branches, being cut off horizontally, four or more grafts are placed round the ſtock, between the bark and the rind, ſomewhat in the manner of a crown. The moſt proper time for performing this is about the latter end of March, or the beginning of April. After the intended number of cions are inſerted, which is done exactly in the ſame manner as that already delivered for grafting in the rind, the whole crown of the ſtock is well clayed over, and only two eyes of each cion are left uncovered; theſe being ſufficient for their ſhooting.

This method of grafting was more practiſed formerly than it is at preſent; many people having been diſcouraged by the ill ſucceſs that has frequently attended the cions, which have been blown out of the ſtock, by ſtrong winds, after they had made large ſhoots, and even after they had grown there five or ſix years. But this accident

may be prevented, by tying the cions to ſtakes faſtened to the tree, till they are ſo firmly fixed, as to have almoſt covered the ſtock.

Root-GRAFTING is a modern invention, the deſign of which is ſomewhat different from that of any of the former methods; this being for the propagation, or multiplication, of plants already fitted to produce their fruit.

To perform this, take a graft, or ſprig, of a young tree, which you intend to propagate, and a ſmall piece of the root of another tree of the ſame kind, or of a like genus, and whip-graft them together; obſerving that the but-ends of the graft and root be well united, and that the rind of the root join cloſely to that of the graft. Theſe may, afterwards, be planted out at pleaſure, and the piece of root will collect the nutritive juices, and feed the graft, as the ſtock does the other way.

This method of propagation is very eaſy and expeditious; roots being more plentiful than ſtocks: by this means the pieces of roots of one crab-ſtock, for example, or of one apple-ſtock, will ſerve for twenty or thirty apple grafts; and the like of other trees. It is alſo an excellent way for raiſing of tender trees, which will hardly bear being grafted in the ſtock. Add, that trees thus graſted bear ſooner, and are more eaſily dwarfed, than thoſe done any other way.

The only objection againſt this method is, that the young tree grows but ſlowly at firſt, which is occaſioned by the ſmallneſs of the root that feeds the graft; for in all trees the head muſt follow the increaſe of the roots, from whence it hath its nouriſhment.

Reiterated GRAFTING, or GRAFTING *by a double*, or *triple Inciſion*, is another method mentioned by Agricola, whoſe work, though chimerical enough in many reſpects, contains, notwithſtanding, ſeveral good things. To perform this, firſt graft a good cion on a ſtock, and cut it away to one half, or a third part; then fix to that remaining part of the cion, another graft, of a better kind; and to that a third; for the oftener the tree is grafted, the finer fruit it produces.

By this method, the author above-mentioned aſſures us, that he produced muſcat pears, which were admirable; making, at firſt, uſe of a ſtock grafted with a pound-pear, on which he grafted a ſummer bon-chretien; and when the branch of this laſt had ſhot, he grafted on it a cion of a bergamo, which he alſo cut, and grafted on it a cion of a muſcat pear.

GRAFTING *of Branches* is alſo commended by Agricola, as a very certain and profitable operation: beſt practiſed on large, full-grown, and even old trees.

To do this, half or more of the branches muſt be lopped off, and grafts of three or four years old be applied to them; taking care to have ſtakes, or other things, to ſupport them againſt the wind, &c.

He adds, that by this method, you will have, perhaps the ſame year, or at leaſt the ſecond or third, ſuch a quantity of fruit, as the youngeſt and ſoundeſt tree would hardly produce.

GRAFTING *by Approach*, called alſo *Inarching*, and *Ablactation*, is uſed only when the tree intended to be grafted, and that from which the graft is to be taken, ſtand ſo near, or can be brought ſo near to each other, that they may be joined together. The method of performing it is thus: The branch to be inarched is fitted to that part of the ſtock where it is to be joined; the rind, and part of the wood, of one ſide of that branch, is then pared away, very ſmooth and even for the length of three inches; and afterwards the other branch, which is to ſerve for the ſtock to which the graft is to be united, is ſerved in the ſame manner, ſo that the two may join cloſely and equally together, that the ſap veſſels may meet. A little tongue is then cut upwards in the graft, and a ſlit is made in the ſtock, to receive it; ſo that when they are joined, the tongue prevents their ſlipping, and the graft is the more cloſely united to the ſtock. When they are thus placed exactly together, they muſt be tied with baſs, worſted, or ſome other ſoft thing; and the place of junction muſt be well covered over with grafting clay, to prevent the air from drying the wound, and the wet from rotting the ſtock. A ſtake muſt alſo be fixed in the ground, and both the ſtock and the graft muſt be tied thereto to prevent their being diſplaced by the wind. When they have remained in this ſtate four months, they will be ſufficiently united, and the graft may then be cut off from the mother tree; obſerving to ſlope it cloſe to the ſtock. It is of great ſervice to the graft then to lay a freſh coat of clay all round the grafted or joined part. This operation ſhould be performed in April or May, that the graft may be perfectly united to the ſtock, before the enſuing winter. It is chiefly practiſed upon oranges, mirtles, jaſmines, firs, pines, and ſome other trees, which do not ſucceed well in the common way of grafting or budding. But, though orange-trees are here mentioned among the reſt, this practice is not to be adviſed for them, or for any other trees, if they are intended to grow large; for that they hardly ever do in this method; and accordingly it is ſeldom uſed but for the curioſity of having a young plant with fruit upon it, in a year or two from its having been raiſed from the ſeed. This is, indeed, effected by inarching a bearing branch into a young ſtock; but the plant ſo treated ſeldom lives long.

The walnut, fig, and mulberry, will alſo take by this method of grafting, though neither of them will ſucceed in any other way: but ſtill, they, like all other trees that are thus managed, will remain weak, and ſtinted in their growth, beſides the ſhortening of their otherwiſe uſual time of duration.

All grafts, particularly of young cions, are ſubject to be injured by birds; but that may be prevented by binding ſome ſmall buſhes about the tops of the ſtocks.

The binding of the grafts, whether it be of baſs or yarn, ſhould be looſened at leaſt, if it be not entirely taken off, at Midſummer, or thereabouts; leſt its then too great tightneſs (as the ſtock will have increaſed in bulk, and the binding perhaps have been ſwelled, and conſequently ſhrunk, by the weather) ſhould injure the plant.

Eſcutcheon GRAFTING. See INOCULATION.

GRAIN, a general name for all ſorts of corn, as wheat, barley, &c.

GRAIN is alſo the name of a ſmall weight, the twentieth part of a ſcruple in apothecaries weight, and the twenty-fourth of a penny-weight troy. See the article WEIGHT.

GRAIN alſo denotes the component particles of ſtones and metals, the veins of wood, &c. Hence croſs-grained, or againſt the grain, is contrary to the fibres of wood, &c.

GRAINING-BOARD, among curriers, an inſtrument called alſo a pummel, uſed to give a grain to their leather. See the article CURRYING.

GRAMEN, graſs, in botany. See the article GRASS.

GRAMEN JUNCEUM, a name uſed by Moriſon for a ſpecies of plantain.

GRAMINEOUS CROWN, in antiquity, the ſame with the obſidional one. See the article CROWN.

GRAMMAR, γραμματικη, the art of ſpeaking and writing any language with propriety.

GRAMMAR is alſo uſed for a book containing the rules of this art, methodically digeſted; of which there are multitudes indeed, but few good ones.

GRAMMARIAN, one that is ſkilled in, or teaches grammar.

GRAMMATICAL, in general, ſomething belonging to grammar. See the article GRAMMAR.

GRANADIER, a ſoldier armed with a ſword, a firelock, a bayonet, and a pouch full of hand-granadoes. They wear high caps, are generally the talleſt and briſkeſt fellows, and are always the firſt upon all attacks.

Every battalion of foot has generally a company of granadiers belonging to it, or elſe four or five granadiers belong to each company of the battalion; which, on occaſion, are drawn out, and form a company of themſelves. Theſe always take the right of the battalion.

Horſe-GRANADIERS, called by the French *grenadiers volans*, or flying-grenadiers, are ſuch as are mounted on horſeback, and fight on foot: their exerciſe is the ſame with the other granadiers.

GRANADILLA, paſſion-flower, a plant called by Linnæus paſſiflora. See the article PASSIFLORA.

GRANADO, a hollow ball or ſhell, of iron or other metal, about two inches and a half in diameter; which being filled with fine powder, is ſet on fire by means of a ſmall fuſee faſtened to the touch-hole, made of the ſame compoſition as that of a bomb: as ſoon as the fire enters the ſhell, it burſts into many pieces, much to the damage of all that ſtand near. See the article BOMB.

Thuanus obſerves, that the firſt time granadoes were uſed, was at the ſiege of Wachtendonck, a town near Gueldres; and that the inventor was an inhabitant of Venlo, who, in making an experiment thereof, occaſioned two-thirds of that city to be burnt, the fire being kindled by the fall of a granado.

GRANARY, a building to lay or ſtore corn in, eſpecially that deſigned to be kept a conſiderable time.

Experimental philoſophy has proved that the air is the great ſource of corruption; keep out that, and all is kept out; and the moſt corruptible ſubſtances, ſuch as meal, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air-pump.

They have, near Grand Cairo, a magazine or granary, defended with good walls, and called Joſeph's granaries. It is not probable that they are quite ſo old as the days of that patriarch, but they abundantly prove the utility of ſuch ſtore-houſes, by the vaſt quantities of grain annually preſerved in them.

Many parts of Africa abound with granaries of this kind.

They are ſo many deep pits made in the ſolid rock; the deſcent into them is but juſt large enough for a man to go down into them by, but they grow larger as ſoon as the perſon is in, and are uſually ſquare, from thirty to forty feet in diameter. In theſe the great men of the country preſerve their corn; they firſt ſtrew over the floor with ſtraw, then they lay on the corn; ſtill, as the heap riſes, placing a thin bed of ſtraw between the corn and the ſides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a ſort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickneſs of ſand, and over this raiſe a ridge of earth, well beat together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine.

The corn thus ſtored up always keeps three, four, or more years very good; and, not unfrequently, the proprietor being taken off by the ſeverity of the eaſtern governments, under which they live, the magazine is forgotten, and ſome accident diſcovering it many years afterwards, the corn is almoſt always found perfectly good in it. All the care they take, in regard to the corn, is to expoſe it two or three days to the ſun's heat, to dry it thoroughly, before they carry it into the magazine.

In the dutchy of Lithuania and in the Ukraine, the people always preſerve their corn in the ſame manner in wells or pits made in dry places; but in theſe countries great care is to be taken in the opening theſe ſtore-rooms; for if people deſcend into them before they have had ſufficient communication with the freſh air, they are often killed by the damps; this, however, is eaſily guarded againſt. By theſe, and numerous other inſtances of the practice of other countries, it appears evident, that the advantage of theſe ſubterranean granaries over all others is very great.

Though theſe are to be recommended before all others, yet the common granaries may, with proper care, be rendered greatly more uſeful than they are at preſent. The grand caution neceſſary to this purpoſe is to guard againſt the too great humidity, which there always is in places where there is a great number of doors and windows. A too free acceſs of the external air is alſo to be carefully guarded againſt; for this brings in with it the eggs of a vaſt number of different inſects, which prey upon and deſtroy the corn. A third caution is, when the corn is the produce of the country, where it is preſerved, not to fill the place with the crop of one place only, but to mix the harveſts of two as different provinces as may be, the one dry, the other moiſt, or otherwiſe differing as much as may be; thus the contrary qualities of the one will prevent the deſtruction of the other. Theſe are the three great rules to prevent the corrupting of corn; but when the miſchief is once begun, it will prove very difficult to ſtop it: all the care that can be employed, ſhould therefore be taken in regard to theſe.

The two great cautions to be obſerved in the erecting of granaries are to make them ſufficiently ſtrong, and to expoſe them to the moſt drying winds. The ordering of the corn in many parts of England is thus: to ſeparate it from duſt and other impurities after it is threſhed, they toſs it with ſhovels from one end to the other of a long and large room; the lighter ſubſtances fall down in the middle of the room, and the corn only is carried from ſide to ſide, or end to end of it. After this, they ſcreen the corn, and, then bringing it into the granaries, it is ſpread about half a foot thick, and turned from time to time about twice in a week; once a week they alſo repeat the ſcreening it. This ſort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the ſeaſon be damp, and now and then ſcreen it again. After about five or ſix months, they raiſe it to five or ſix feet thickneſs in the heaps, and then they turn it once or twice in a month, and ſcreen it now and then. When it has lain two years, or more, they turn it once in two months, and ſcreen it once a quarter, and, how long ſoever it is kept, the oftener the turning and ſcreening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every ſide the heap of corn, and other empty ſpaces, into which they turn and toſs the corn, as often as they find occaſion. In Kent they make two ſquare holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and ſo up again, to turn and air it the better. Their ſcreens are made with two partitions, to ſeparate the duſt from the corn which falls into a bag; and when ſufficiently full, this is thrown away, the pure and good corn remaining behind.

Corn has by theſe means been kept in our granaries thirty years; and it is obſerved, that the longer it is kept, the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the ſuperfluous humidity only evaporating in the keeping. At Zurich, in Switzerland, they keep corn eighty years or longer, by the ſame ſorts of methods.

The public granaries at Dantzick are ſeven, eight, or nine ſtories high, having a funnel in the midſt of every floor to let down the corn from one to another. They are built ſo ſecurely, that though every way ſurrounded with water, the corn contracts no damp, and the veſſels have the convenience of coming up to the walls for their lading. The Ruſſians preſerve their corn in ſubterranean granaries of the figure of a ſugar-loaf, wide below, and narrow at top: the ſides are well plaiſtered, and the top covered with ſtones. They are very careful to have the corn well dried before it is laid into theſe ſtore-houſes, and often dry it by means of ovens; the ſummer dry weather being too ſhort to effect it ſufficiently.

GRAND, a term borrowed from the French, implying the ſame with great.

GRAND-JURY, the jury who find bills of indictment at the ſeſſions, &c. of the peace.

GRANGE, a houſe or farm furniſhed with granaries and barns for holding corn, ſtables for horſes, ſtalls for cattle, &c.

GRANIFEROUS *Pods*, among botaniſts, are ſuch as contain ſmall ſeeds reſembling grain.

The word is compounded of the Latin, *granum*, grain, and *fero*, to bear.

GRANITE, *Granita*, in natural hiſtory, a diſtinct genus of ſtones, compoſed of ſeparate and very large concretions, rudely compacted together, of great hardneſs, and capable of receiving a very beautiful poliſh.

GRANIVOROUS, in natural hiſtory, an epithet given to animals that feed on corn or ſeed.

The word is compounded of the Latin, *granum*, grain, and *vora*, to devour.

GRANULATION, in metallurgy, the action of reducing

ducing metals to ſmall particles in order to promote their fuſion and mixture with other bodies.

GRAPES, the fruit of the vine. See the article VINE.

GRAPHOMETER, among ſurveyors, an inſtrument for taking angles, and generally called a ſemi-circle. See SEMI-CIRCLE.

GRAPPLING, in the ſea language, a ſort of ſmall anchor with four or five flukes or arms, commonly uſed to ride a boat. See the article ANCHOR.

Fire-GRAPPLING, an inſtrument nearly reſembling the above, only that it is fitted with ſtrong barbs in the room of flukes; and is fixed at the yard-arms of a fire-ſhip to grapple her adverſary, and ſet her on fire.

GRASS, *Gramen*, in botany, a general name for moſt of the herbaceous plants uſed in feeding cattle.

The beſt ſeaſon for ſowing graſs ſeed is the latter end of Auguſt, and the beginning of September, that the graſs may be well rooted before the froſt ſet in, which is apt to turn the plants out of the ground, when they are not well rooted. This ſeed ſhould be ſown in moiſt weather, or when there is a proſpect of ſhowers, which will ſoon bring the graſs up; for, the earth being at that ſeaſon warm, the moiſture will cauſe the ſeed to vegetate in a few days: but, where this cannot be performed in autumn, the ſeeds may be ſown in the ſpring; towards the middle of March will be a good time, if the ſeaſon proves favourable.

The land on which graſs ſeed is intended to be ſown, ſhould be well plowed, and cleared from the roots of noxious weeds, ſuch as couch graſs, fern, ruſhes, heath, gorſe, broom, reſt-harrow, &c. which, if left in the ground, will ſoon get the better of the graſs, and over-run the land. Therefore, in ſuch places where either of theſe weeds abound, it will be a good method to plow up the ſurface in April, and let it lie ſome time to dry; then lay it in ſmall heaps, and burn it. The aſhes ſo produced, when ſpread on the land, will be a good manure for it. The method of burning the land is particularly uſeful; eſpecially, if it is a cold ſtiff ſoil; but where couch graſs, fern, or reſt-harrow, is in plenty, whoſe roots run far under ground, the land muſt be plowed two or three times pretty deep in dry weather, and the roots carefully harrowed off each plowing; which is the moſt ſure method to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome underground drains to carry off the wet; which, if detained too long on the ground, will render the graſs ſour. The method of making theſe drains is preſcribed under the article LAND, which ſee.

Before the ſeed is ſown, the ſurface of the ground ſhould be made level and fine, otherwiſe the ſeed will be buried unequal. The quantity of graſs-ſeed for an acre of land is uſually three buſhels, if the ſeed is clean, otherwiſe there muſt be a much greater quantity allowed; when the ſeed is ſown, it muſt be gently harrowed in, and the ground rolled with a wooden roller; which will make the ſurface even, and prevent the ſeeds being blown in patches. When the graſs comes up, if there ſhould be any bare ſpots, where the ſeed has not grown, they may be ſown again, and the ground rolled, which will fix the ſeeds; and the firſt kindly ſhowers will bring up the graſs, and make it very thick.

Some people mix clover and rye graſs together, allowing ten pounds of clover, and one buſhel of rye graſs, to an acre: but this is only to be done where the land is deſigned to remain but three or four years in paſture, becauſe neither of theſe kinds are of long duration; ſo that, where the land is deſigned to be laid down for many years, it will be proper to ſow with the graſs-ſeed ſome white trefoil, or Dutch clover; which is an abiding plant, and ſpreads cloſe on the ſurface of the ground, ſending forth roots at every joint; and makes the cloſeſt ſward of any, and is the ſweeteſt feed for cattle: ſo that, whenever land is laid down to paſture, there ſhould always be ſix or eight pounds of this ſeed ſown upon each acre.

The following ſpring, if there ſhould be any thiſtles, ragwort, or ſuch other troubleſome weeds, come up among the graſs, they ſhould carefully be cut up with a ſpaddle before they grow large; and this ſhould be repeated two or three times in the ſummer, which will effectually deſtroy them; for, if theſe plants are ſuffered to ripen their ſeeds, they will be blown all over the ground; their ſeeds having down adhering to them, which aſſiſts their tranſportation; ſo that they are often carried by the wind to a great diſtance, and thereby become very troubleſome weeds to the graſs. For want of this care, how many paſtures may be ſeen almoſt over-run with theſe weeds, eſpecially the ragwort; when a ſmall expence, if applied in time, would have intirely extirpated them! for a man may go over ſeveral acres of land in one day with a ſpaddle, and cut up the weeds juſt below the ſurface of the ground, turning their roots upwards; which if done in dry weather, they will ſoon decay; but this muſt always be performed before the plants come to have their ſeeds formed; becauſe after that many ſorts will live long enough to nouriſh their ſeeds after they are cut, ſo as to ripen them: and there will be a ſupply of weeds for ſome years after, which cannot be extirpated without a much greater expence.

The proper management of paſture land is the leaſt underſtood of any part of agriculture: the farmers never have attended to this, being more inclined to the plough; though the profit attending that has not of late years been ſo great as to encourage them in that part of huſbandry: but theſe people never think of laying down land for paſture, to continue longer than three years; at the end of which time they plow it up again, to ſow it with grain.

Their uſual method is to ſow rye graſs and trefoil with barley, when they intend to lay down the ground; or ſometimes ſow only clover with the barley; nor is it poſſible to convince theſe people of their error in ſowing corn with this graſs; which they affirm to be uſeful in ſhading the graſs; not conſidering how much the corn draws away the nouriſhment from the graſs: but it is in vain to write to theſe people, who are not to be convinced, either by argument or experiment; ſo much are they led by cuſtom, as not to be led or driven out of their own methods; but, as their practice of huſbandry has greatly leſſened the circumſtances of the farmers, ſo that the lands are daily falling into the hands of the owners, therefore, this part of huſbandry ſhould by them be principally attended to, as it may be carried on with a much leſs expence: for paſture land requires but few hands to manage; whereas the ſowing of corn is attended with great expence, and the profit is very precarious: but, when this is attended with ſucceſs, and the grain at a moderate price, if the whole labour is to be paid for, there will be little coming to the owner for rent, when the balance is fairly ſtated; but in this moſt gentlemen deceive themſelves, and often ſuppoſe they gain by farming, when, perhaps, the whole rent of the land is loſt: therefore, to avoid the trouble which attends this ſort of huſbandry, it will be the beſt method to turn as much of their land into paſture, as they can; which, by grazing and feeding of ſheep, will be attended with little expence, and a ſure profit.

As to graſs plats and green walks, they are made, for the moſt part, not by ſowing graſs-ſeed, but by laying turfs: and indeed the turfs from a fine common or down, are much preferable to ſown graſs: but if walks or plats are to be made by ſowing, the beſt way is to procure the ſeed from thoſe paſtures where the graſs is naturally fine and clear, or elſe the trouble of keeping it from ſpiry or benty graſs will be very great, and it will ſcarce ever look handſome.

In order to ſow graſs-walks, the ground muſt be firſt dug; and when it has been firſt dreſſed and laid even, it muſt be very carefully raked over, and all the clods and ſtones taken off, and then covered over an inch thick with good mould. This being done, the ſeed is to be ſown pretty thick, that it may come up cloſe and ſhort; it muſt then be raked over again, to cover the ſeed, that if the weather ſhould happen to be windy, it may not be blown away. It ought alſo to be obſerved, that where graſs is ſown in gardens, either for lawns or walks, there ſhould always be a good quantity of the white trefoil or Dutch clover ſown with it; for this will make a fine turf much ſooner than any other ſown graſs, and will continue a better verdure than any other of the graſs-tribe.

In order to keep graſs-plats or walks handſome, and in good order, you may ſow in autumn freſh ſeed over any places that are not well filled, or where the graſs is dead: but nothing improves graſs ſo much, as mowing and conſtant rolling.

When turf is laid in gardens, it is a general practice to cover the ſurface of the ground under the turf, either with ſand or very poor earth: the deſign of this is to keep the graſs fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not ſo for ſuch land as is but middling, or poor; for when this is practiſed in ſuch places, the graſs will ſoon wear out and decay in patches.

When turf is taken from a common or down, ſuch ought to be choſen as is free from weeds: and when it is deſigned to remain for years without renewing, a dreſſing ſhould be laid upon it every other year, either of very rotten dung, aſhes, or where it can be eaſily procured, very rotten tan; but theſe dreſſings ſhould be laid on early in the winter, that the rain may waſh them into the ground, otherwiſe they will occaſion the graſs to burn, when the warmth of the ſummer begins. Where graſs is ſo dreſſed, and kept well rolled and mowed, it may be kept very beautiful for many years: but where it is not dreſſed, or fed with ſheep, it will rarely continue handſome more than eight or ten years.

GRASSHOPPER, in zoology, a ſpecies of the gryllus, frequent in paſtures. See GRYLLUS.

GRATINGS, in ſhip-building, certain hatches or covers laid over the hatchways of a ſhip, and croſſed with battens of wood, ſo as to let the light down between the decks of a ſhip. See HATCHES.

GRAVE, in muſic, is applied to a ſound of a low or deep tone.

GRAVE *Accent*, in grammar, is a mark placed in this manner [`] over ſome vowel, and implies that the voice ſhould be lowered in pronouncing that ſyllable.

GRAVEL, in natural hiſtory, is a congeries of ſmall pebbles, which being mixed with a ſtiff loam, makes laſting and elegant walks in our gardens.

Opinions with regard to the choice of gravel, are various; ſome are for having it as white as poſſible, and in order to render it the more ſo cauſe the walks to be often rolled with ſtone rollers, which add a whiteneſs to the ſurface. But this renders them very troubleſome to the eyes, by reflecting too ſtrongly the rays of light: ſuch gravel therefore as will lie ſmooth and reflect the leaſt, ſhould be preferred. Again, ſome ſcreen the gravel too fine, but this is an error; for if it be caſt into a round heap, and the great ſtones only are raked off, it will be the better. There are many kinds of gravel which do not bind, and by this means cauſe a continual trouble of rolling, to little or no purpoſe; as for ſuch, if the gravel be looſe or ſandy, you ſhould take one load of ſtrong loam and two of gravel, and ſo caſt them well together.

The month of March is the propereſt time for laying gravel; for it is not prudent to do it ſooner, or to lay walks in any of the winter-months before that time. In making theſe walks, great regard muſt be had to the level of the ground, ſo as to lay the walks with eaſy deſcents toward the low parts of the ground, that the wet may be eaſily drained off: but when the ground is level, it will be proper to have ſink-ſtones laid by the ſides of the walk, and at convenient diſtances, to let off the wet; and when the ground is naturally dry, the drains from the ſink-ſtones may be contrived ſo as to convey the water into ſeſſpools, from which the water will ſoak away in a ſhort time: but in wet lands there ſhould be underground drains, to convey the water off, either into ponds, ditches, or the neareſt place proper to receive it.

Some are apt to lay gravel walks too round; but this is an error, becauſe they are not ſo good to walk upon; and beſides, it makes them look narrow; one inch is enough in a crown of five feet; and it will be ſufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each ſide: if fifteen feet, three inches; if twenty feet, four inches; and ſo in proportion.

For the depth of gravel-walks, ſix or eight inches may do well enough; and a foot in thickneſs will be ſufficient for any; but then there ſhould always be a depth of rubbiſh laid under the gravel, eſpecially if the ground be wet.

Some turn up gravel walks into ridges in December, in order to kill the weeds: but this is very wrong, ſince it never anſwers the end, and therefore if conſtantly rolling them after rain and froſt will not effectually kill the weeds and moſs, you ſhould turn the walks in March, and lay them down at the ſame time.

In order to deſtroy worms that ſpoil the beauty of gravel or graſs walks, ſome recommend the watering them with water made very bitter by ſteeping walnut-tree leaves in it; but if in the firſt laying of the walks there be a good bed of lime rubbiſh laid at the bottom, it will prove the moſt effectual method to keep out the worms, for they never harbour near lime.

GRAVEL, in medicine, a very painful diſtemper ariſing from a gritty matter concreting into ſmall ſtones in the kidnies and bladder. See the article STONE.

GRAVELLING, an accident that often happens to a horſe in travelling, occaſioned by ſmall gravel-ſtones getting between the hoof and the ſhoe, where they feſter and fret the part.

It is cured by taking off the ſhoe, picking out all the gravel, waſhing the part affected, and then pouring hot upon it a compoſition of ſheep's tallow and bay ſalt melted together.

GRAVELLY *Land*, that which abounds with gravel and ſand.

The beſt manure of theſe lands is marl, or any ſtiff clay that will diſſolve with the froſt, cow dung, chalk, mud, and half rotten ſtraw from the dung-hill.

GRAVER, the name of a tool by which all the lines, ſcratches, and ſhades, are engraved on copper, &c.

There are three ſorts of gravers, round-pointed, ſquare-pointed, and lozenge-pointed. The round are beſt for ſcratching; the ſquare pointed for cutting the larger ſtrokes; and the lozenge pointed for the moſt delicate ſtrokes: but a graver of a middle form between the ſquare and lozenge-pointed will make the ſtrokes or hatches appear with more life and vigour. See ENGRAVING.

GRAVING, among ſeamen, the act of cleaning a ſhip's bottom. See CAREEN and DOCK, where this operation is particularly explained.

GRAVITATION, in philoſophy, the preſſure which one body exerts upon another by reaſon of its gravity. See the article ATTRACTION.

GRAVITY, the natural tendency which all bodies have towards a center. See ATTRACTION.

GRAVITY, in mechanics, the tendency of bodies towards the center of the earth. Gravity is of two kinds, abſolute and relative, or ſpecific.

Abſolute GRAVITY is the whole force with which a body tends downwards, or towards the center of the earth, and is always equal to the quantity of matter the body contains, without any regard to its bulk; ſo that the abſolute gravity of a pound of wood is equal to that of a pound of iron.

Relative or *Specific* GRAVITY is the exceſs of gravity in one body above that of another of equal dimenſions, and is always proportionable to the quantity of matter under that dimenſion. Thus a cubic inch of iron is heavier than a cubic inch of wood; for the iron being more denſe than the wood, contains a greater quantity of matter under the ſame bulk.

For the method of finding the ſpecific gravities of bodies, ſee the article *Hydroſtatical* BALANCE.

GRAVITY *of the Air*. See AIR and ATMOSPHERE.

GRAY, or GREY, in horſemanſhip. See the article GREY.

GREASE, in farriery, a ſwelling and gourdineſs of the legs of a horſe.

This diſeaſe is generally the effects of a faulty blood, and happens moſtly to horſes of a groſs conſtitution; ſometimes it is owing to careleſſneſs in the perſons that look after them, for want of keeping their limbs clean and dry; but for the moſt part horſes that run late in the winter at graſs are the moſt ſubject to it; their blood by that means growing poor and dropſical, expoſes them firſt to ſwell in their limbs, and then to eruptions, which diſcharge a fœtid ſtinking matter reſembling melted glue, and when it turns ſharp and corroſive, it becomes very trou-

troubleſome. Sometimes the greaſe breaks out only behind, ſometimes before; and when the conſtitution is very bad, it will break out in all the four limbs at the ſame time.

When the heels are very much ſwelled and full of hard ſcabs, it is neceſſary to begin the cure with poultices, which may be made with either turneps or rye-flower, turpentine, and hogs lard, mixed with ſpirit of wine or red wine-lees; and when the horſe comes to move his limbs with leſs ſtiffneſs, it will be proper to purge him, which, in ſome caſes, muſt be repeated five or ſix times before you can obtain the deſired effect. Where there are pretty large ſwellings in the limbs, diuretics that work powerfully by urine, often ſucceed better than purges.

Molten GREASE, a diſtemper incident to very fat horſes from over-riding, or any violent exerciſe.

It is known by the horſe's voiding a greaſy matter with his dung; though this ſymptom ſometimes attends fat horſes that ſtand much in the ſtable, and have but very little exerciſe, on their catching the leaſt cold. But when a horſe's greaſe is really melted, it is always accompanied with a fever, heat, reſtleſſneſs, ſtarting tremors or tremblings, great inward ſickneſs, ſhortneſs of breath, and ſometimes with the ſymptoms of a pleuriſy.

In order to cure this diſeaſe, it is neceſſary to bleed plentifully in order to empty the veſſels; and ſeveral rowels or iſſues ſhould be cut in different parts of his body. Glyſters are alſo of great ſervice, and ought to be rather of the emollient kind, than purgative, as they are principally intended to cool the inteſtines; all the other internals ought likewiſe to be cleanſing, attenuating, and opening.

GREAT, a term of compariſon, applied to things of large or extraordinary dimenſions, &c.

GREAT *Circles of the Sphere*, are ſuch as divide the ſphere into two equal parts or hemiſpheres, in contradiſtinction to the leſſer circles, which cut the ſphere into unequal parts. See SPHERE.

GREAT *Circle Sailing*. See the article SAILING.

GREECE, the preſent Rumelia, and the ancient Hellas, one of the moſt famous republics of antiquity, is ſituated between 36 and 44 degrees of north latitude; and between 20 and 26 degrees of eaſt longitude. It is in general a very healthy and fruitful country, extending from the Adriatic ſea to the Archipelago.

GREEK, or GRECIAN, ſomething relating to ancient Greece.

GREEK *Bible*. See the article BIBLE.

GREEK *Church*, that part of the Chriſtian church eſtabliſhed in Greece and other parts of Turkey.

GREEK *Language*, the language ſpoken by the ancient Greeks, and ſtill preſerved in the writings of Plato, Ariſtotle, Demoſthenes, Thucydides, Xenophon, Homer, Heſiod, &c.

The Greek language was that of a people who had a taſte for the arts and ſciences, which they happily cultivated; and hence it abounds with very ſignificative terms, which are often borrowed by the moderns, and applied to any new diſcovery, inſtrument, machine, &c.

GREEK *Orders*, in architecture, are the Doric, Ionic, and Corinthian; the other two, namely, the Tuſcan and Compoſite, being called the Latin orders.

GREEN, one of the original colours of the rays of light. See the article COLOUR.

GREEN, among painters and dyers, is a colour produced by a mixture of yellow and blue, which will be either deeper or lighter in proportion to the quantity of yellow uſed in the compoſition.

GREEN-CLOTH, a board or court of juſtice, held in the compting-houſe of the king's houſhold, compoſed of the lord-ſteward, and the officers under him, who ſit daily, and take cognizance of matters of juſtice within the verge of the court, which extends about two hundred yards every way from the laſt gate of the palace where his majeſty reſides.

GREEN-FINCH, in ornithology, the Engliſh name of the greeniſh fringilla, having its wings and tail variegated with yellow. It is a very common bird with us, and ſomething larger than the chaffinch.

GREENHOUSE, a conſervatory, or houſe erected in a garden, for preſerving ſuch tender and exotic plants as cannot bear the cold of our winters, if expoſed to the open air.

The following deſcription of a green-houſe is taken from Mr. Miller's Gardener's Dictionary, as the conſervatory given by that ingenious gardener is very well adapted to this climate.

The length of theſe houſes muſt be proportioned to the number of plants they are intended to contain; but their depth ſhould never be greater than their height in the clear; which, in ſmall or middling houſes, may be ſixteen or eighteen feet, and in large ones from twenty to twenty four. The windows in front ſhould extend from about one foot and a half above the pavement, to within the ſame diſtance of the ceiling, which will admit of a corniche round the building, over the heads of the windows. In a ſmall green-houſe the ſaſhes ſhould not be leſs than four or five feet broad; and in a large one, they ought not to exceed ſeven and a half; the ſhutters of which ought to fall back cloſe to the piers on the inſide, that, when open, they may not prevent any of the rays of light from reaching the plants. The piers between theſe windows, ſupporting the building, ſhould be as narrow as poſſible; for which reaſon they ſhould be either of ſtone or well-burnt brick. If they are of ſtone, they ought not to exceed two feet and a half in front, and ſhould be ſloped off backward to about eighteen inches broad; by which means the rays of the ſun will not be obſtructed by the corners of the piers, as they would be if they were ſquare: but if they are built of brick, it will be proper to make them near three feet in front, otherwiſe they will be too weak to ſupport the building: theſe I would alſo adviſe to be ſloped off in the manner directed for the ſtone.

At the back of the green-houſe, there may be erected an houſe for tools, and many other purpoſes; which will be extremely uſeful, and alſo prevent froſt from entering the houſe that way; ſo that the wall between theſe need not be more than two bricks and an half in thickneſs; whereas, were it quite expoſed behind, it ſhould be at leaſt three bricks in thickneſs; and by this contrivance, if you are willing to make an handſome building, and to have a noble room over the green-houſe, you may make the room over the tool-houſe, and carry up the ſtair-caſe in the back, ſo as not to be ſeen in the green-houſe; and hereby you may have a room twenty-five or thirty feet in width, and of a proportionable length: and, under this ſtair caſe, there ſhould be a private door into the green-houſe, at which the gardener may enter in hard froſty weather, when it will not be ſafe to open any of the glaſſes in the front. The floor of the green-houſe, which ſhould be laid either with marble, ſtone, or broad tiles, according to the fancy of the owner, muſt be raiſed two feet above the ſurface of the ground whereon the houſe is placed; which, in dry ground, will be ſufficient: but if the ſituation be moiſt and ſpongy, and thereby ſubject to damps, it ſhould be raiſed at leaſt three feet above the ſurface: and if the whole is arched with low brick arches under the floor, it will be of great ſervice in preventing the damps riſing in winter, which are often very hurtful to the plants, eſpecially in great thaws, when the air is often too cold to be admitted into the houſe, to take off the damps. Under the floor, about two feet from the front, I would adviſe a flue of about ten inches in width, and two feet deep, to be carried the whole length of the houſe, which may be returned along the back part, and be carried up in proper funnels adjoining to the tool-houſe, by which the ſmoke may paſs off. The fire-place may be contrived at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool-houſe, ſo that it may be quite hid from the ſight, and be in the dry; and the fuel be laid in the ſame place, whereby it will always be ready for uſe.

I ſuppoſe many people will be ſurpriſed to ſee me direct the making flues under a green-houſe, which has been diſuſed ſo long, and by moſt people thought of ill conſequence; as indeed they have often proved, when under the direction of unſkilful managers, who have thought it neceſſary, whenever the weather was cold, to make fires therein. But however injurious flues have been under ſuch management, yet, when ſkilfully managed,

naged, they are of very great ſervice: for, though perhaps it may happen that there will be no neceſſity to make any fires in them for two or three years together, as, when the winters prove mild, there will not, yet, in very hard winters, they will be extremely uſeful to keep out the froſt; which cannot be effected any other way, but with great trouble and difficulty.

Withinſide of the windows, in front of the green-houſe, you ſhould have good ſtrong ſhutters, which ſhould be made with hinges, to fold back, that they may fall back quite cloſe to the piers, that the rays of the ſun may not be obſtructed thereby. Theſe ſhutters need not to be above an inch and an half thick, or little more; which, if made to join cloſe, will be ſufficient to keep out our common froſt: and, when the weather is ſo cold as to endanger the freezing in the houſe, it is but making a fire in your flue, which will effectually prevent it: and without this conveniency it will be very troubleſome, as I have often ſeen, where perſons have been obliged to nail mats before their windows, or to ſtuff the hollow ſpace between the ſhutters and the glaſs with ſtraw; which, when done, is commonly ſuffered to remain till the froſt goes away; which, if it ſhould continue very long, the keeping the green-houſe cloſely ſhut up will prove very injurious to the plants: and as it frequently happens, that we have an hour or two of ſunſhine in the middle of the day, in continued froſts, which is of great ſervice to plants, when they can enjoy the rays thereof through the glaſſes; ſo, when there is nothing more to do than to open the ſhutters, which may be performed in a very ſhort time, and as ſoon ſhut again when the ſun is clouded, the plants may have the benefit thereof, whenever it appears; whereas, where there is ſo much trouble to uncover, and as much to cover again, it would take up the whole time in uncovering and ſhutting them up, and thereby the advantage of the ſun's influence be loſt. Beſides, where there is ſo much trouble required to keep out the froſt, it will be a great chance if it be not neglected by the gardener: for, if he be not as fond of preſerving his plants, and as much in love with them, as his maſter, this labour will be thought too great by him; and, if he takes the pains to cover the glaſſes up with mats, &c. he will not care to take them away again, until the weather alters; ſo that the plants will be ſhut up cloſe during the whole continuance of the froſt.

There are ſome people who commonly make uſe of pots filled with charcoal to ſet in their green-houſe in very ſevere froſts; but this is very dangerous to the perſons who attend theſe fires; and I have often known they have been almoſt ſuffocated therewith; and at the ſame time they are very injurious to the plants: nor is the trouble of tending upon theſe ſmall; and the many hazards, to which the uſe of theſe fires is liable, have juſtly brought them into diſuſe with all ſkilful perſons; and as the contrivance of flues, and of the fires, are but ſmall charges, they are much to be preferred to any other method for warming the air of the houſe.

The back part of the houſe ſhould be either laid over with ſtucco, or plaſtered with mortar, and white-waſhed; for otherwiſe the air in ſevere froſt will penetrate through the walls, eſpecially when the froſt is attended with a ſtrong wind; which is often the caſe in the moſt ſevere winters. There are ſome perſons who are at the expence of wainſcoting their green-houſes; but, when this is done, it is proper to plaſter with lime and hair behind the wainſcot, to keep out the cold; and, when they are lined with wainſcot, they ſhould be painted white, as ſhould the ceiling, and every part withinſide of the houſe: for this reflects the rays of light in much greater quantity than any other colour, and is of ſignal ſervice to plants, eſpecially in the winter, when the houſe is pretty much cloſed, and but a ſmall ſhare of light is admitted through the windows: for, at ſuch times, I have obſerved, that in ſome green-houſes which have been painted black, or of a dark colour, the plants have caſt moſt of their leaves.

Where green-houſes are built in ſuch places as will not admit of rooms over them, or the perſon is unwilling to be at the expence of ſuch building, there muſt be care taken to keep out the froſt from entering through the roof. To prevent which, it will be very proper to have a thickneſs of reeds, heath, or furz, laid between the ceiling and the tiles: in the doing of which, there muſt be care taken in framing the joiſts, ſo as to ſupport theſe, that their weight may not lie upon the ceiling, which might endanger it: for theſe ſhould be laid a foot thick at leaſt, and as ſmooth as poſſible, and faſtened down well with laths, to prevent their riſing; and then cover it over with a coat of lime and hair, which will keep out the air, and alſo prevent mice, and other vermin, from harbouring in them; which, if left uncovered, they would certainly do. For want of this precaution, there are many green-houſes built, which will not keep out the froſt in hard winters; and this is many times attributed to the glaſſes in front admitting the cold, when the fault is in the roof: for where there is only the covering, either of tiles or ſlates, and the ceiling, every ſevere froſt will penetrate through them.

In this green-houſe you ſhould have treſſels, which may be moved out and into the houſe; upon which you ſhould fix rows of planks, ſo as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants will be ſo ſituated as not to interfere with each other. The loweſt row of plants, which ſhould be the forwardeſt towards the windows, ſhould be placed about four feet therefrom, that there may be a convenient breadth left next the glaſſes to walk in front: and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner, that the heads of the ſecond rows ſhould be entirely advanced above the firſt, the ſtems only being hid thereby; and, at the backſide of the houſe, there ſhould be allowed a ſpace of at leaſt five feet, for the conveniency of watering the plants; as alſo to admit of a current of air round them, that the damps, occaſioned by the perſpiration of the plants, may be the better diſſipated, which, by being pent in too cloſely, often occaſions a mouldineſs upon the tender ſhoots and leaves; and when the houſe is cloſe ſhut up, this ſtagnating rancid vapour is often very deſtructive to the plants: for which reaſon alſo you ſhould never croud them too cloſe to each other, nor ſhould you ever place ſedums, euphorbiums, torch thiſtles, and other tender ſucculent plants, amongſt oranges, myrtles, and other ever-green-trees; for, by an experiment which I made anno 1729, I found that a ſedum, placed in a green-houſe among ſuch trees, almoſt daily increaſed its weight, although there was no water given to it the whole time; which increaſe of weight was owing to the moiſture imbibed from the air, which, being replete with the rancid vapours perſpired from the other plants, occaſioned the leaves to grow pale, and in a ſhort time they decayed, and dropped off; which I have often obſerved has been the caſe with many other ſucculent plants, when placed in thoſe houſes which were filled with many ſorts of ever-green trees, that required to be frequently watered.

Therefore, to avoid the inconvenience which attends the placing of plants of very different natures in the ſame houſe, it will be very proper to have two wings added to the main green-houſe; which, if placed in the manner expreſſed in the annexed plan, will greatly add to the beauty of the building, and alſo collect a greater ſhare of heat. In this plan, the green-houſe is placed exactly fronting the ſouth; and one of the wings faces the ſouth-eaſt, and the other the ſouth-weſt; ſo that, from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it is conſtantly reflected from one part to the other; and the cold winds are alſo kept off from the front of the main green-houſe hereby: and, in the area of this place, you may contrive to place many of the moſt tender exotic plants, which will bear to be expoſed in the ſummer ſeaſon: and in the ſpring, before the weather will permit you to ſet out the plants, the beds and borders of this area may be full of anemonies, ranunculus's, early tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground, by the time you carry out the plants; which will render this place very agreeable during the ſpring ſeaſon that the flowers are blown; and here you may walk and divert yourſelf in a fine day, when, perhaps, the air in moſt other parts of the garden will be too cold for perſons not much uſed thereto, to take pleaſure in being out of the houſe.

5 JA 59

In the center of this area may be contrived a ſmall baſon for water, which will be very convenient for watering of plants, and add much to the beauty of the place: beſides, the water, being thus ſituated, will be ſoftened by the heat, which will be reflected from the glaſſes upon it; whereby it will be rendered much better than raw cold water for theſe tender plants.

The two wings of the building ſhould be contrived ſo as to maintain plants of different degrees of hardneſs; which muſt be effected by the ſituation and the extent of the fire-place, and the manner of conducting the flues; a particular account of which will be exhibited under the article STOVES. But I would here obſerve, that the wing facing the ſouth-eaſt ſhould always be preferred for the warmeſt ſtove; its ſituation being ſuch, as that the ſun, upon its firſt appearance in the morning, ſhines directly upon the glaſſes; which is of great ſervice in warming the air of the houſe, and adding life to the plants, after having been ſhut up during the long nights in the winter ſeaſon. Theſe wings being, in the draught annexed, allowed ſixty feet in length, may be divided in the middle by partitions of glaſs, with glaſs doors to paſs from one to the other. To each of theſe there ſhould be a fire-place, with flues carried up againſt the back wall, thro' which the ſmoke ſhould be made to paſs, as many times the length of the houſe, as the height will admit of the number of flues; for the longer the ſmoke is in paſſing, the more heat will be given to the houſe, with a leſs quantity of fuel; which is an article worth conſideration, eſpecially where fuel is dear. By this contrivance, you may keep ſuch plants as require the ſame degree of heat in one part of the houſe, and theſe will thrive in a much leſs warmth in the other part; but this will be more fully explained under the article STOVES.

The other wing of the houſe, facing the ſouth-weſt, may alſo be divided in the ſame manner, and flues carried through both parts, which may be uſed according to the ſeaſons, or the particular ſorts of plants which are placed therein; ſo that here will be four diviſions in the wings, each of which may be kept up to a different degree of warmth: which, together with the green-houſe, will be ſufficient to maintain plants from all the ſeveral countries of the world; and, without having theſe ſeveral degrees of warmth, it will be impoſſible to preſerve the various kinds of plants from the ſeveral parts of Africa and America, which are annually introduced into the Engliſh gardens; for when plants from very different countries are placed in the ſame houſe, ſome are deſtroyed for want of heat, while others are forced and ſpoiled by too much of it; and this is often the caſe in many places, where there are large collections of plants.

In the building theſe wings, if there are not ſheds running behind them their whole length, the walls ſhould not be leſs than two bricks thick; and if they are more, it will be better; becauſe, where the walls are thin, and expoſed to the open air, the cold will penetrate them; and when the fires are made, the heat will come out thro' the walls; ſo that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the houſe. The back part of theſe houſes, having ſloping roofs, which are covered either with tiles or ſlates, ſhould alſo be lined with reeds, &c. under the covering, as is before directed for the green-houſe; which will keep out the cold air, and ſave a great expence of fuel; for the cloſer and better theſe houſes are built, and the glaſſes of the ſlope, as alſo in front, well guarded by ſhutters or reeds in a hard froſt, the leſs fuel will be required to warm the houſes; ſo that the firſt expence of building theſe houſes properly will be the cheapeſt, when the after expence of fires is taken into conſideration.

The ſloping glaſſes of theſe houſes ſhould be made to ſlide, and take off; ſo that they may be drawn down more or leſs, in warm weather, to admit air to the plants; and the upright glaſſes in front may be ſo contrived, as that every other may open as doors upon hinges; and the alternate glaſſes may be divided into two: the upper part of each ſhould be contrived ſo as to be drawn down like ſaſhes; ſo that either of theſe may be uſed to admit air, in a greater or leſs quantity, according as there may be occaſion.

But, beſides the conſervatories here mentioned, it will be proper to have a deep hot bed frame, ſuch as is commonly uſed to raiſe large annuals in the ſpring; into which may be ſet pots of ſuch plants as come from Carolina, Virginia, &c. while the plants are too ſmall to plant in the open air; as alſo may other ſorts from Spain, &c. which require only to be ſcreened from the violence of the froſts, and ſhould have as much free air as poſſible in mild weather; which can be no better effected than in one of theſe frames, where the glaſſes may be taken off every day when the weather will permit, and put on every night; and in hard froſts, the glaſs may be covered with mats, ſtraw, peaſe haulm, or the like, ſo as to prevent the froſt from entering the pots to freeze the roots of the plants, which is what will, many times, utterly deſtroy them; though a ſlight froſt pinching the leaves or ſhoots very ſeldom does them much harm: if theſe are ſunk a foot or more below the ſurface of the ground, they will be the better, provided the ground is dry; otherwiſe they muſt be wholly above ground: the ſides of this frame ſhould be built with brick, with a curb of wood laid round on the top of the wall, into which the gutters, on which the glaſſes ſlide, may be laid: the back wall of this frame may be four feet high, and the front one foot and an half; the width about ſix feet, and the length in proportion to the number of plants.

Explanation of plate LXXII. *fig.* 3, 4, 5, 6, repreſenting a plan, elevation, &c. of a green-houſe.

A; *fig.* 6, the ground plan of a green-houſe.

B B, the ground plan of the two ſtoves.

C C C, the ſheds behind the green-houſe.

D D, the paſſage of communication between the green-houſe and ſtoves, where the ſtairs are placed which lead to the rooms over the green houſe.

E E, *fig.* 3, 4, ſection of the flues in the back of the ſtoves.

F, *fig.* 5, the elevation of the green-houſe.

GREGARIOUS, an epithet applied to ſuch animals as live together in flocks or herds.

GREGORIAN *Calendar*. See the article CALENDAR.

GREGORIAN *Year*. See YEAR.

GREWT, among miners, implies earth of a different colour from the reſt, found on the banks of rivers as they are ſearching for mines.

GREY, or GRAY, a mixed colour compounded of black and white. See COLOUR.

GRIFFON, in heraldry, an imaginary animal, ſuppoſed by the ancients to be half eagle and half lion.

GRINDING, *Trituratio*, the reducing hard ſubſtances to fine powders, by means of mills, rubbing them in a mortar, or with a muller on a marble.

GRIPE, in huſbandry, a ſmall ditch cut acroſs a meadow or ploughed land, in order to drain it.

GRIPES, among ſailors, certain ropes hooked to the decks of a ſhip, and drawn tight over the boats, to ſecure and prevent them from being ſhaken by the agitation of a ſhip at ſea.

GRIPING, in the ſea language, the inclination of a ſhip to run to the windward of her courſe, when ſhe ſteers with a wind on either quarter.

This is partly occaſioned by the ſhock of the waves which ſtrike her on the weather-quarter, but chiefly by the arrangement of the ſails, which diſpoſe her at ſuch a time to edge continually to windward. See the article QUARTER.

GRIST, in country affairs, implies corn already ground or ready for grinding.

GROAT, an Engliſh money of account, equal to four-pence.

GROGRAM, among manufacturers, a kind of ſtuff compoſed of ſilk and mohair.

GROIN, *Pubes*, in anatomy; ſee PUBES.

GROOM, a name applied to ſeveral ſuperior officers belonging to the king's houſhold.

GROOM is more particularly uſed for a ſervant appointed to attend horſes in the ſtable.

GROMMET, among ſailors, a ſort of wreath or ring of rope to faſten a ſail to any ſtay, upon which it is drawn along at the time of hoiſting and lowering it, by

the help of theſe grommets, as a curtain is extended or drawn together along its rod by the aſſiſtance of rings.

GROOVE, among miners, the ſhaft or pit ſunk into the earth, whether in the vein or not.

GROOVE, among joiners, implies the channel made by their plough in the edge of a moulding, &c.

GROSS-WEIGHT, among merchants, ſignifies the whole weight of any commodity, including the duſt, droſs, and bag, cheſt, &c. in which it is contained.

GROSSULARIA, the gooſeberry and currant-buſhes. See RIBES and GOOSEBERRY.

GROTESQUE, ſomething whimſical, extravagant, and monſtrous.

GROTTO, in natural hiſtory, a large deep cavern in ſome rock or mountain.

GROTTO is alſo uſed for a ſmall artificial edifice made in a garden, in imitation of a natural grotto.

The outſides of theſe grottos are uſually adorned with ruſtic architecture, and their inſide with ſhell-work, coral, &c. and alſo furniſhed with various fountains, and other ornaments.

The following is recommended as a good cement for grotto-work. Take two parts of white roſin, melt it clear, add to it four parts of bees-wax; when melted together, add ſome flower of the ſtone you deſign to cement, two or three parts, or ſo much as will give the cement the colour of the ſtone; to this add one part of the flower of ſulphur: firſt incorporate all together over a gentle fire, and afterwards knead it with your hands in warm water. With this faſten the ſtones, ſhells, &c. after they are well dried, and warmed before the fire.

Artificial and red corals, for the embelliſhment of grottos, may be made in the following manner: Take two drams of the fineſt vermilion; and when you have ſtirred them well together, and choſen your twigs and branches, which muſt be peeled and dried, take a pencil and paint the branches all over, whilſt the compoſition is warm; afterwards ſhape them in imitation of natural coral. This done, hold the branches over a gentle coal fire, till all is ſmooth and even, as if poliſhed.

In the ſame manner white coral may be prepared with white lead, and black coral with lamp-black.

A grotto may be built with a little expence of glaſs, cinders, pebbles, pieces of large flints, ſhells, moſs, ſtones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above deſcribed cement.

GROVE, in gardening, a ſmall wood impervious to the rays of the ſun.

Groves are the greateſt ornaments to a garden; nor can a garden be complete which has not one or more of theſe. In ſmall gardens there is ſcarce room to admit of groves of any extent; yet, in theſe, there ſhould be at leaſt one contrived, which ſhould be as large as the ground will allow it: and, where theſe are ſmall, there is more ſkill required in the diſpoſition, to give them the appearance of being larger than they really are.

Groves are of two ſorts, viz. open and cloſe groves; open groves are ſuch as have large ſhady trees, which ſtand at ſuch diſtances, as that their branches may approach ſo near each other, as to prevent the rays of the ſun from penetrating through them: but as ſuch trees are a long time in growing to a proper ſize for affording a ſhade; ſo, where new groves are placed, the trees muſt be placed cloſer together, in order to have ſhade as ſoon as poſſible; but, in planting of theſe groves, it is much the beſt way to diſpoſe all the trees irregularly, which will give them a greater magnificence, and alſo form a ſhade ſooner, than when the trees are planted in lines; for, when the ſun ſhines between the rows of trees, as it muſt do ſome part of the day in ſummer, the walks between them will be expoſed to the heat, at ſuch times, until the branches of theſe trees meet; whereas, in the irregular plantations, the trees intervene, and obſtruct the direct rays of the ſun.

When a perſon, who is to lay out a garden, is ſo happy as to meet with large full grown trees upon the ſpot, they ſhould remain inviolate, if poſſible; for it will be better to put up with many inconveniencies, than to deſtroy theſe, which will require an age to retrieve; ſo that nothing but that of offending the habitation, by being ſo near as to occaſion great damps, ſhould tempt the cutting of them down.

Moſt of the groves which have been planted either in England, or thoſe celebrated gardens in France, are only a few regular lines of trees; many of which join to the habitation, or lead to ſome building, or other object: but theſe do not appear ſo grand, as thoſe which have been made in woods, where the trees have grown accidentally, and at irregular diſtances; where the trees have large ſpreading heads, and are left at ſuch diſtance as to permit the graſs to grow under them, then they afford the greateſt pleaſure; for nothing is more noble, than fine ſpreading trees, with large ſtems, growing through graſs, eſpecially if the graſs is well kept, and has a good verdure; beſide, moſt of theſe planted groves have generally a gravel walk, made in a ſtraight line between them; which greatly offends the ſight of perſons who have a true taſte: therefore, whenever a gravel walk is abſolutely neceſſary to be carried through theſe groves, it will be much better to twiſt it about, according as the trees naturally ſtand, than to attempt regularity: but dry walks under large trees are not ſo uſeful, as in open places; becauſe the dropping of the trees will render theſe walks uſeleſs, after rain, for a conſiderable time.

Cloſe groves have frequently large trees ſtanding in them; but the ground is filled under theſe with ſhrubs, or under-wood; ſo that the walks which are made in them are private, and ſcreened from winds; whereby they are rendered agreeable for walking, at ſuch times when the air is too violent or cold for walking in the more expoſed parts of the garden.

Theſe are often contrived ſo as to bound the open groves, and frequently to hide the walls, or other incloſures, of the garden: and when they are properly laid out, with dry walks winding through them, and on the ſides of theſe ſweet-ſmelling ſhrubs and flowers irregularly planted, they have a charming effect: for here a perſon may walk in private, ſheltered from the inclemency of cold or violent winds, and enjoy the greateſt ſweets of the vegetable kingdom: therefore, where it can be admitted, if they are continued round the whole incloſure of the garden, there will be a much greater extent of walk: and theſe ſhrubs will appear the beſt boundary where there are not fine proſpects to be gained.

Theſe cloſe groves are by the French termed boſquets, from the Italian word boſquetto, which ſignifies a little wood: and in moſt of the French gardens there are many of them planted; but theſe are reduced to regular figures, as ovals, triangles, ſquares, and ſtars: but theſe have neither the beauty or uſe which thoſe have that are made irregularly, and whoſe walks are not ſhut on each ſide by hedges, which prevents the eye from ſeeing the quarters; and theſe want the fragrancy of the ſhrubs and flowers, which are the great delight of theſe private walks; add to this, the keeping of the hedges in good order is attended with a great expence; which is a capital thing to be conſidered in the making of gardens. *Miller's Gard. Dict.*

GROUND, in agriculture; ſee EARTH and SOIL.

GROUND, in painting, the ſurface upon which the figures and other objects are repreſented.

The ground is properly underſtood of ſuch parts of the piece as have nothing painted on them, but retain the original colours upon which the other colours are applied to make the repreſentations.

A building is ſaid to ſerve as a ground to a figure, when the figure is painted on the building.

The ground behind a picture in miniature is commonly blue or crimſon, imitating a curtain of ſattin or velvet; if it be to be blue, it ſhould be laid on as follows: waſh bice till it is very pure and clear, and temper a quantity in a ſhell ſufficient for your ground, letting it be thoroughly moiſt and well bound with gum. Then with a ſmall pencil lay on the ſame colour about the pourfile, that is, the ambient ſuperficies of the picture; having done this, take a large pencil, and waſh over the whole ground you deſign to cover with a blue, ſomewhat thin and wateriſh, and then with a pretty large pencil, full of colour and flowing, lay over with a thick and ſubſtantial colour what you had before only waſhed over; in the doing

doing of this you muſt be very quick, keeping the colour you have laid on moiſt, and not ſuffering any part to dry till you have covered the whole.

If you would have your ground a crimſon like ſattin, then trace out where and in what places you will have thoſe ſtrong and hard lights and reflections to fall, which are ſeen in ſattin or velvet, with Indian lake; there lay your lights with a lake that is thin and wateriſh, and while it is yet wet, lay the deepening and hard ſtrong ſhadows with a ſtronger and darker colour of lake thick ground, cloſe by the other lights. The beſt way for imitation, is to have a piece of ſattin before you to imitate.

GROUND, in etching; ſee the article ETCHING.

GROUND-ANGLING, a method of angling without a float, only with a plumb of lead, or rather a bullet, becauſe it will roll on the ground.

GROUND-IVY, hedera terreſtris, in botany; ſee HEDERA TERRESTRIS.

GROUND-PINE, in botany; ſee CHAMEPITYS.

GROUND-TACKLE, among ſailors, all ſorts of ropes which belong to the anchors, or for mooring a ſhip, as cables, hawſers, tow-lines, warps, buoy ropes, &c.

GROUND-WORK, among builders; ſee FOUNDATION.

GROUNDING, in the ſea-language, a ſhip is ſaid to ground when ſhe ſtrikes and reſts upon the ground.

GROUNDSEL, in botany; ſee ERYERON.

GROUP, in painting and ſculpture, an aſſemblage of two or more figures, of men, beaſts, fruits, &c. which have ſome apparent reſemblance to one another.

It is neceſſary in a good piece of painting, that all the figures be divided into groups: this has ſomewhat in it of the nature of ſymphony or concert of voices; for as in the one the voices muſt ſuſtain each other, in order to fill the ear with an agreeable harmony from the whole; ſo in groups, if the parts or figures be not well diſpoſed, ſomething will be found diſagreeable.

There are two kinds of groups, or two manners of conſidering them, with reſpect to the deſign, and to the clair-obſcure. The firſt of theſe is common both to works of painting and ſculpture; but the latter is peculiar to painting.

Groups, with reſpect to the deſign, are combinations of ſeveral figures, which bear a relation to each other, either upon account of the action, or of their proximity, or of the effect they produce. Theſe we conceive as repreſenting ſo many different ſubjects, or at leaſt ſo many diſtinct parts or members of one great ſubject. Thus, in architecture, we ſay a group of columns, when we ſpeak of three or four columns ſtanding together on the ſame pedeſtal.

Groups, with reſpect to the clair-obſcure, are aſſemblages of figures, where the lights and ſhadows are diffuſed in ſuch a manner, that they ſtrike the eye together, and naturally lead it to conſider them in one view.

GROUSE, or GROWSE, the name of a very valuable bird, of the ſize of a full-grown fowl. Its head is large, and adorned with a very beautiful ſcarlet protuberance over the eyes, which are remarkably piercing. It is a native of England, though not very common, and lives on large mountainous heaths.

GROWAN, among the Corniſh miners, implies a coarſe gritty ſtone of a greyiſh colour, which they are often obliged to dig through, before they reach the tin ore.

GRUB, the Engliſh name of the hexapode worms, or maggots, hatched from the eggs of beetles.

Grubs are an excellent bait for many kinds of fiſh. In angling for the grayling, the aſh-grub is to be preferred to all others. This is plump, milk-white, but round from head to tail, and has a red head. There is alſo another grub, which is very common, and is longer and ſlenderer than the aſh-grub. It is yellower and tougher, and is known by having a red head, and two rows of legs along the belly. The trout and grayling uſually frequent the ſame places, and it is not uncommon to take the trout, while fiſhing for the other. Theſe grubs are to be kept in bran, in which they will grow tougher than they were at firſt; but the aſh-grub is always ſo tender, that it is difficult to make a good bait of it. The beſt method is to wrap it in a piece of ſtiff hair with the arming, leaving it ſtanding out above a ſtraw's breadth at the head of the hook, ſo as to keep the grub from totally ſlipping off, when baited. The horſe-hair that the hook is faſtened to ſhould be as white as poſſible, that it may reſemble the colour of the bait, and not be ſuſpected.

GRUBS, in medicine, certain unctuous pimples riſing on different parts of the face, particularly in the alæ of the noſe. They are cured by cooling phyſic, and ſuch medicines as have a tendency to cleanſe the blood.

GRUBBING, a term uſed by our farmers to ſignify the taking up the roots of trees.

Several occaſions offer for the doing this; as when trees are old and paſt growing to any uſe, the roots muſt be taken up, that young trees may be planted in their places. This is a chargeable operation in moſt places, but, in ſome countries, the farmers have deviſed a machine, which does a great part of the work in a much ſhorter time than in any other way can be done. It is a hook of iron, of about two feet and a half long, with a large iron ring faſtened to its ſtraight end or handle. The whole inſtrument may be made for about three or four ſhillings, and is to be uſed in this manner: the ground is firſt to be cleared away about the root, and any ſtraggling ſide roots found running horizontally are to be cut off. Then they faſten the point of the hook to ſome part of the ſtump or root, and, putting a long and ſtrong lever through the ring, two men at the end of it go round forcing it every way, till they tear the root out, twiſting the top roots off at ſome diſtance under ground; the digging down to which, in the common way, is one great article of the expence. It is very effectual in ſtubbing up the roots of the underwood, but, when large tree roots are to be taken up by it, it is beſt to cleave them firſt with wedges into ſeveral pieces, and then pull them out ſeparately. *Mortimer's Huſbandry.*

GRUME, *Grumus*, in medicine, implies a concreted clot of blood, milk, or other ſimilar ſubſtance.

GRUS, the crane, in ornithology, a bird of the heron kind. See CRANE.

GRYLLOTALPA, the mole cricket, in natural hiſtory, a creature approaching to the locuſt kind, and very properly called by this name by Moffet, as it has much of the form of the cricket, and makes a noiſe like it in the evening; and is, like the mole, continually employed in the digging the ground. It is an inſect of a very unpleaſant form. It is of the length and thickneſs of a man's little finger, and is of a brown colour; which is darker in the male than in the female. There are on each ſide of the anus two hairy proceſſes, reſembling the tails of mice; its belly is compoſed of eight joints, and is covered with as many ſcales, which are of a pale fleſh colour, and are covered with ſhort hair. The back is covered by a pair of pointed wings, along each of which there runs a black ſtreak or line. Theſe wings fold any way at the creature's pleaſure, and, when fully expanded, are very large. Over theſe lie the antennæ; theſe are variegated alſo with black, and reach about half the length of the wings. It has only four legs; the hinder pair are long and fit for hopping; the anterior pair are ſhort, and furniſhed with a ſort of hands for digging, in the manner of the mole. The breaſt is covered with a cruſtaceous ſubſtance which is blackiſh, and hairy on the outſide, and ſmooth and pale within. The eyes are very bright and black, and very hard; the mouth is wide, and has two tonſils, and teeth in both jaws. The creature lives under ground, and is principally found in damp and boggy places.

GRILLUS, in zoology, the name of the cricket and locuſt kind, which, together with the graſshopper, form one genus of inſects.

GUAIACUM, in the materia medica, the wood of two kinds of trees growing in America, called by Plukenet, the one *guaiacum Jamaicenſe*, &c. the Jamaica guaiacum-tree, with bright green roundiſh leaves like thoſe of the maple; the other *euonymo adfinis occidentalis*, &c. an occidental nut bearing tree, allied to the euonymus or ſpindle-tree, with winged leaves, like thoſe of butcher's broom, and a fungous bark at the joints. The wood comes over in large pieces, weighing four, five, and more hundred weight, from Jamaica, Mexico, Porto-rico, Boriquen,

riquen, St. Domingo, and other parts of the Weſt Indies: the tree has been raiſed alſo in Europe, but proved far inferior in quality to that produced in its native climate, and yielded nothing of the reſinous juice, which it plentifully bleeds there.

This wood is remarkably hard, compact, and ſo heavy as to ſink in water; of a brown, or yellowiſh-brown colour, often blackiſh, or marbled as it were with different colours. When the tree is ſtanding or newly felled, the bark adheres ſo firmly as not to be got off even with iron tools; after lying for ſome time it ſeparates eaſily. On account of its great hardneſs, ſolidity, and indiſpoſition to crack, it is employed by the turners and others for ſeveral of the more curious mechanic uſes. In Holland, at Hamburg, and other places of large commerce, it is raſped in workhouſes eſtabliſhed for that purpoſe, after the ſame manner as the colouring-woods; and from theſe the druggiſt and apothecary are ſupplied.

Guaiacum is a very reſinous wood: on expoſing it to a moderate heat, the reſin viſibly melts out. By digeſtion in highly rectified ſpirit of wine, I obtained three ounces and a half of reſinous extract from ſixteen ounces of the wood: ſuch as had been boiled in water till that menſtruum would take up no more, yielded ſtill, with rectified ſpirit, two ounces of reſin upon the pound. Water applied at firſt extracts an ounce and a half, and after ſpirit has performed its office half an ounce and two ſcruples of gummy matter. The indiſſoluble part, when the gum was extracted firſt, weighed twelve ounces and a half; when the reſin was firſt extracted, only twelve ounces and two drams. Theſe experiments were made with chips of a good reſinous kind of guaiacum. The raſped wood commonly ſold yields leſs of a reſinous and more of a gummy extract. From a pound of good raſpings I obtained by ſpirit two ounces and ſix drams, and afterwards by water one ounce: another pound of the ſame, treated with water at firſt, gave two ounces, and afterwards with ſpirit one ounce and ſix drams.

A ſtrong decoction of guaiacum is uſed as an alterative diet-drink in venereal, cancerous, and other diſorders from an impurity of the blood and juices. Hoffman recommends the ſpirituous extract (which is the moſt active preparation) as a high antidote againſt the venereal poiſon, provided it be uſed properly, according to the laws of medicine. He mentions alſo another reſinous preparation of this wood, under the title of "A ſingular reſin, "of a ſtimulating errhine quality, and poſſeſſing alſo a "corroborating power, highly friendly to the nervous "parts of the head." This, according to his account, is the reſin that precipitates in boiling down a watery decoction of the wood. *Neumann's Chemiſtry.*

Gum-GUAIACUM, ſo called, is a reſin exuding from the guaiacum-tree. It is of a brown colour, partly reddiſh, and often greeniſh, brittle, of a gloſſy ſurface when broke, of a pungent taſte; and when rubbed or heated, of a not diſagreeable ſmell: its ſmoke, in burning, has ſomewhat the ſmell of that of wood. Such ſhould be choſen as has pieces of the bark adhering, and eaſily parts from them by a few quick blows. The maſſes which have no bark, eſpecially the large ones, are often ſophiſticated. I received for gum-guaiacum, a whole box of an artificial compoſition of colophony and balſam of ſulphur: this abuſe was readily diſtinguiſhable by the ſmell of the compound when laid upon burning coals, and even by its appearance upon breaking.

Out of an ounce of gum-guaiacum, rectified ſpirit of wine diſſolves ſix drams and two ſcruples: of the remainder, water applied at firſt, extracts four ſcruples out of an ounce: of the reſiduum, ſpirit diſſolves four drams and two ſcruples. In diſtillation, it gives over a little both to water and to ſpirit, ſo little as to be altogether inconſiderable.

Its virtues are the ſame with thoſe of the wood. It is uſed pretty frequently in England, very rarely in Germany, the pure reſin artificially extracted from the wood by means of ſpirit of wine, advantageouſly and elegantly ſupplying its place. *Neumann's Chemiſtry.*

GUAJAVA, or GUAVA, in botany, the name by which Tournefort calls the pſidium of Linnæus. See PSIDIUM.

GUANABANUS, the cuſtard apple, in botany, a genus of plants whoſe characters are:

The empalement of the flower conſiſts of three ſmall pointed leaves: the flowers of ſome ſorts have only three, but in others ſix petals; in the latter, three are alternately leſs than the others: from the empalement ariſes the pointal, which afterwards becomes an oval or round fleſhy ſoft fruit, incloſing ſeveral oblong ſmooth hard ſeeds.

All theſe plants, which are natives of the warm parts of America, are too tender to live in this country, if they are not preſerved in warm ſtoves: they come up very eaſily from the ſeeds which are brought from America, if they are freſh: but the ſeeds muſt be ſown on a good hot bed, or in pots of light earth, and plunged into an hot bed of tanners bark. Theſe ſeeds ſhould be ſown as ſoon as poſſible when they ariſe, unleſs it is very late in the autumn, or in winter; in which caſe, they ſhould not be ſown till February; becauſe if the ſeeds receive much damp in the winter, they will rot; and if the plants ſhould come up at that ſeaſon, it will be very difficult to preſerve them till ſpring; ſo that, when theſe ſeeds come to England, pretty early in the ſpring, it is by much the beſt time; becauſe the plants come up early, and will have time to get ſtrength, before the cold comes on.

If theſe plants are kept in the bark ſtove, and carefully managed, they will make great progreſs; but in warm weather, they ſhould have plenty of freſh air admitted to them; for, when the air is excluded from them too much, they are apt to grow ſickly; when they will ſoon be attacked by vermin, which will multiply and ſpread over the whole ſurface of the leaves, and cauſe them to decay: but, if the plants are carefully managed, their leaves will continue green all the winter, and make a very good appearance in the ſtove at that ſeaſon.

There are ſome of theſe plants in England, which are upwards of twelve feet high, and have produced flowers; ſo that they may probably produce fruit here. As theſe plants advance in their growth, ſo they become more hardy, and ſhould have a greater ſhare of air admitted to them, eſpecially in the ſummer: but there ſhould be great care taken, not to let them remain in the bark bed too long unremoved; becauſe they are very apt to root thro' the holes of the pots into the tan; and then theſe roots will be torn off, whenever the pots are removed, and the plants ſeldom ſurvive this; and, when they do, it is generally a long time before they perfectly recover their former vigour. Theſe plants, when young, will require to be kept in the ſame degree of warmth with ananas; but as they get more ſtrength, ſo they will thrive with leſs warmth. *Miller's Gard. Dict.*

GUARANTY, in policy, the engagement of neutral kingdoms or ſtates, whereby they undertake that certain treaties ſhall be inviolably obſerved.

GUARD, in a general ſenſe, ſignifies the defence or preſervation of any thing; the act of obſerving what paſſes, in order to prevent ſurprize; or the care, precaution, and attention we make uſe of, to prevent any thing happening contrary to our intention or inclinations.

GUARD, in the military art, is a duty performed by a body of men, to ſecure an army or place from being ſurpriſed by an enemy.

In a garriſon the guards are relieved every day, and it comes to every ſoldier's turn once in three days; ſo that they have two nights in bed, and one upon guard.

To be upon guard, to mount the guard, to diſmount the guard, to relieve the guard, to change the guard, the officer of the guard, or the ſerjeant of the guard, are words often uſed, and well underſtood.

Advanced-GUARD is a party of either horſe or foot, that marches before a more conſiderable body, to give notice of any approaching danger.

When an army is upon the march, the grand-guards which ſhould mount that day, ſerve as an advanced-guard to the army: in ſmall parties, ſix or eight horſe are ſufficient, and theſe are not to go above four or five hundred yards before the party.

An advanced-guard is alſo a ſmall body of twelve or ſixteen horſe, under a corporal, or quarter-maſter, poſted before the grand-guard of a camp.

Artillery-GUARD is a detachment from the army to ſecure the artillery; their corps de garde is in the front, and

and their centries round the part. This is a forty-eight hours guard: and upon a march, they go in the front and rear of the artillery, and muſt be ſure to leave nothing behind; if a gun or waggon break down, the captain is to leave a part of his guard to aſſiſt the gunners and matroſſes in getting it up again.

Corps de GARDE, are ſoldiers entruſted with the guard of a poſt, under the command of one or more officers.

Counter-GUARD, in fortification. See the article COUNTER-GUARD.

Forrage-GUARD, a detachment ſent out to ſecure the forragers, which are poſted at all places, where either the enemy's party may come to diſturb the forragers; or where they may be ſpread too near the enemy, ſo as to be in danger of being taken. They conſiſt both of horſe and foot, and muſt ſtay at their poſts till the forragers all come off the ground.

Grand-GUARD, three or four ſquadrons of horſe, commanded by a field-officer, poſted at about a mile and a half from the camp, on the right and left wings, towards the enemy, for the ſecurity of the camp.

Main-GUARD, that from whence all the other guards are detached.

Thoſe who are to mount the guard, meet at their reſpective captain's quarters, and go from thence to the parade; where, after the whole guard is drawn up, the ſmall guards are detached for the poſts and magazines; and then the ſubaltern officers throw lots for their guards, and are commanded by the captain of the main-guard.

Picquet-GUARD, a good number of horſe and foot always in readineſs in caſe of an alarm: the horſe are all the time ſaddled, and the riders booted. The foot draw up at the head of the battalion, at the beating of the tattoo; but afterwards return to their tents, where they hold themſelves in readineſs to march, upon any ſudden alarm. This guard is to make reſiſtance, in caſe of an attack, till the army can get ready.

Quarter-GUARD, a ſmall guard, commanded by a ſubaltern officer, poſted by each battalion, about an hundred yards before the front of the regiment.

Rear-GUARD, that part of the army which brings up the rear, which is generally the old grand-guards of the camp. The rear-guard of a party is ſix or eight horſe, that march about four or five hundered paces behind the party. The advanced-guard of a party on its going out, make the rear-guard on its return.

Standard-GUARD, a ſmall guard, under a corporal, out of each regiment of horſe, and placed on foot, in the front of each regiment.

Van-GUARD, that part of the army which marches in the front.

GUARDS alſo imply the troops kept to guard the king's perſon.

Yeomen of the GUARDS. See YEOMEN.

GUARD, in fencing, implies a poſture proper to defend the body from the ſword of the antagoniſt.

GUARD-BOAT, in naval affairs, a boat commanded by a lieutenant, appointed to row around the ſhips in a harbour to ſee that the officers in each ſhip obſerve their watch, and call to the boat as ſhe paſſes, and do not ſuffer them to board without a watch-word.

GUARD-SHIP, a veſſel of war appointed to ſuperintend the marine affairs in a harbour or river, and ſee that the ſhips who are not commiſſioned have their proper watch kept duly every night alſo to receive and ſecure ſeamen who are impreſſed in the time of war.

GUARDIAN, in law, a perſon who has the charge or cuſtody of ſuch perſon or perſons as have not ſufficient diſcretion to take care of themſelves; as ideots, or children under age.

GUAZUMA, baſtard cedar-tree, in botany, a genus of trees whoſe characters are:

It hath a regular flower conſiſting of five leaves, which are hollowed like a ſpoon at their baſe; but at their tops are divided into two parts, like a fork; the flower cup conſiſts of three leaves, from whence ariſes the pointal, which afterward becomes a roundiſh warted fruit, which has five cells incloſing many ſeeds.

Theſe plants may be propagated by ſeed, which ſhould be ſown early in the ſpring, in ſmall pots filled with freſh light earth, and plunged into a hot-bed of tanners bark. When the plants appear above ground, they muſt be carefully cleared from weeds, and often refreſhed with water; and the glaſſes muſt be raiſed to admit freſh air to them, otherwiſe they will draw up too weak: and, when they are about three inches high, they muſt be ſhaken out of the pots filled with light freſh earth; and then plunge them into the hot-bed again, being careful to ſcreen them from the heat of the ſun, until they have taken new root. In this bed the plants may remain all the ſummer, being careful to keep them clear from weeds; and, when the plants have filled the ſmall pots with their roots, they ſhould be ſhaken out, and their roots trimmed, and then put into pots a ſize larger. About Michaelmas the plants muſt be removed into the ſtove, and plunged into the tan in a warm part of the ſtove. During the winter ſeaſon, they will not require ſo much water as in ſummer: if their leaves ſhould contract filth, it muſt be carefully waſhed off with a ſponge; for, if it is ſuffered to remain on them, it will greatly injure the plants. Theſe plants being very tender, they muſt conſtantly remain in the ſtoves, giving them a good ſhare of freſh air in the ſummer; but in winter, they muſt be kept very warm, otherwiſe they will not live in this country; but, if they are carefully managed, they will thrive very well, and afford an agreeable variety in the ſtove, amongſt other tender exotic plants of the ſame countries. *Miller's Gard. Dict.*

GUIDON, the name of a ſort of ſtandard carried by the king's life-guards; ſo called from its being broad at one extreme, and almoſt pointed at the other, and ſlit, or divided into two.

GUIDON alſo implies the officer who carries the guidon.

GUILD, or GILD, a Saxon word ſignifying a company, or fraternity.

GUILDHALL, the chief hall of a city or corporation where the courts are held.

GUINEA-PIG, in zoology, a quadruped of the rat kind, with a variegated body, reſembling in ſome meaſure that of a young pig, whence the name.

GUITAR, a muſical inſtrument of the ſtringed kind, uſed greatly in Spain, and at preſent in England.

GULA, in anatomy, the ſame with œſophagus. See OESOPHAGUS.

GULA, or GOLA, in architecture, the ſame with cymatium, or ogee. See CYMATIUM and OGEE.

GULES, in heraldry, the true ſcarlet colour, and expreſſed in engraving by lines falling perpendicular from the top of the eſcutcheon to the bottom.

GULPH, in geography, a part of the ſea almoſt ſurrounded by the land.

GUM, in pharmacy, a concreted vegetable juice, which tranſudes through the bark of certain trees, and hardens upon the ſurface.

The chemiſts allow only thoſe to be properly gums, which are diſſolvable in water; thoſe which are only diſſolvable in ſpirits, they call reſins; and thoſe of a middle nature, gum-reſins. Geoffroy ſays, that gums are ſomething between acid and oil; being an acid ſalt ſo fixed in earth, as that the greateſt part of it is changed to an alkali, the other into oil; ſo that the mixture ariſing from thence is an oily ſalt reſembling the ſaponaceous concretes of the chemiſts, made of oil of olives, and a lixivium of tartar; or the mucilaginous bodies formed of ſpirit of wine, and the volatile ſpirit of urine.

The reader will find an account of the various ſubſtances, many of which are improperly ſtiled gums, under ARABIC, SENECA, TRAGACANTH, AMMONIACUM, ANIME, GUAIACUM, LACCA.

GUM, among gardeners, a kind of gangrene incident to fruit-trees of the ſtone kind, ariſing from a corruption of the ſap, which, by its viſcidity, not being able to make its way through the fibres of the tree, is, by the protruſion of other juice, made to extravaſate and ouze out upon the bark.

When the diſtemper ſurrounds the branch, it admits of no remedy, but when only on one part of a bough, it ſhould be taken off to the quick, and ſome cow-dung clapped on the wound, covered over with a linnen-cloth, and tied down. M. Quintinie directs to cut off the morbid branch two or three inches below the part affected.

GUM-APPLES, in Languedoc, and ſome other parts of France. The juice of apples will ſometimes exſudate through their rind, and congeal all about them in form of a clear white gum, hard like ice, by reaſon of its being ſoon dried in the ſun into a thin cake. The people call ſuch an apple, pomme gelée, or a frozen apple. It is very common to ſee apples covered in part with this gum in ſeveral ſpecks; but it is more rare to meet with them wholly ſo. The gum is inſipid to the taſte.

We have one plant cultivated in ſome gardens, which yields, in the heat of ſummer, ſuch another white icy and taſteleſs gum. This is the common rhubarb, of the ſtalks of the leaves of which tarts are made. The ribs of the larger leaves of this plant, in June and July, are covered with large tranſparent drops of this gum, and an ounce of it may be ſometimes collected from a ſingle plant. *Phil. Tranſ.* N°. 224.

GUMS, *Gingivæ*, in anatomy; ſee GINGIVÆ.

GUM-BOILS, a morbid affection of the gums called by the writers of ſurgery parulides. Theſe are of different degrees, and uſually ariſe from pains in the teeth. They are to be treated by diſcutients or other inflammatory tumors, but if theſe fail, or the diſorder is neglected, it uſually terminates in an abſceſs or fiſtula. Sage, camomile, and elder flowers, boiled in milk and water, make a good gargariſm to be held in the mouth, and the remaining herbs may be ſewed up in a bag to be kept hot to the cheek. A half roaſted fig is a very good internal application, and, when the ſoftneſs of the tumor ſhews that the matter is ſuppurated, it ought immediately to be opened with the lancet, to prevent the matter's lodging there, and eroding the bone, and producing a fiſtula or caries. After it is opened, the matter ſhould be gently preſſed out with the fingers, and the mouth frequently waſhed with red wine mixed with a decoction of vulnerary herbs till it is well. When the ulcer has penetrated deep, it will be neceſſary to inject the ſame liquors with a ſyringe, and compreſs the part by a proper external bandage, to make the bottom part heal firſt; and, when it is already become fiſtulous, and has callous edges, it may then often be cured by injecting tincture of myrrh, and elixir proprietatis, continuing this for ſome time. If all theſe prove ineffectual, the fiſtula muſt be laid open by inciſion, and the caries removed by medicines, cauſtics, or the actual cautery. If this proceeds, as ſometimes it does, from a carious tooth, this is firſt to be drawn before any thing elſe can be done; and it is a good rule in theſe caſes always to be rather too ſoon than too late in laying them open. *Heiſter's Surg.*

GUN, a fire-arm, or weapon of offence, which forcibly diſcharges a ball, ſhot, or other offenſive matter, through a cylindrical barrel, by means of gun-powder. See the article GUN-POWDER.

Gun is a general name, under which are included divers or even moſt ſpecies of fire-arms, They may be divided into great and ſmall.

Great guns, called alſo by the general name cannons, make what we alſo call ordnance, or artillery; under which come the ſeveral ſorts of cannons, as cannon-royal, demi-cannon, &c. Culverins, demi-culverins, ſakers, minions, falcons, &c. See CANNON, CULVERIN, &c. as alſo ORDNANCE and ARTILLERY.

Small guns include muſquets, muſquetoons, carabines, blunderbuſſes, fowling-pieces, &c. See the article MUSQUET, &c.

Piſtols and mortars are almoſt the only ſort of regular weapons, charged with gun-powder, that are excepted from the denomination of guns. See the articles PISTOL and MORTAR.

GUN is alſo a name given by the miners to an inſtrument uſed in cleaving rocks with gun-powder. It is an iron cylinder of a inch and a quarter thick, and about ſix inches long, and having a flat ſide to receive the ſide of a wedge, and a hole drilled thro' it to communicate with the inſide of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it are put about two or three ounces of gun-powder; then this gun is driven forcibly in, ſo as to fill up the hole, and the wedge is driven in on its flat ſide to ſecure it. The priming at the hole is then fired by a train, and, the orifice being ſo well ſtopped by this gun, the force of the powder is determined to the circumjacent parts of the rock which it ſplits.

GUNNEL, in ſhip-building, the upper-part of a ſhip's ſide.

GUNNER, an officer appointed for the ſervice of the artillery; or a perſon ſkilled in the art of gunnery.

GUNNER *of a Ship of War*, an officer appointed to take charge of the artillery and ammunition aboard; and to teach the men the exerciſe of great guns.

GUNNERY, the art of determining the motion of bodies ſhot from mortars, cannon, &c. See the article PROJECTILE.

The late ingenious Mr. Robins having concluded, from the experiments related in his New Principles of Gunnery, that the force of fired gun-powder, at the inſtant of its exploſion, is the ſame with that of an elaſtic fluid of a thouſand times the denſity of common air, and that the elaſticity of this fluid, like that of air, is proportional to its denſity, propoſes the following problem:

The dimenſions of any piece of artillery, the weight of its ball, and the quantity of its charge, being given; to determine the velocity which the ball will acquire from the exploſion, ſuppoſing the elaſticity or force of the powder at the firſt inſtant of its firing to be given.

In the ſolution of this important problem, he aſſumes the two following principles: 1. That the action of the powder on the bullet ceaſes as ſoon as the bullet is got out of the piece. 2. That all the powder of the charge is fired, and converted into an elaſtic fluid, before the bullet is ſenſibly moved from its place.

Theſe aſſumptions, and the concluſions above-mentioned, make the action of fired gun-powder to be entirely ſimilar to that of air condenſed a thouſand times; and from thence it will not be difficult to determine the velocity of the ball ariſing from the exploſion: for the force of the fired powder diminiſhing in proportion to its expanſion, and ceaſing when it is got out of the piece; the total action of the powder may be repreſented by the area of a curve, the baſe of which repreſents the ſpace through which the ball is accelerated, while the ordinates repreſent the force of the powder at every point of that ſpace: and theſe ordinates being in reciprocal proportion to their diſtance from the breech of the gun, becauſe when the ſpaces occupied by the fired powder, are as 1, 2, 3, 4, &c. the ordinates repreſenting it, will be as 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. it appears that the curve will be a common parabola, and that the area intercepted between it, its aſymptote, and the two ordinates repreſenting the force of the powder at the firſt exploſion, and at the muzzle of the piece, will repreſent the total action of the powder on the ball: but if the ball were urged through the ſame ſpace by an uniform force equal to its gravity, the total action of this force would be repreſented by a rectangle, the baſe of which would be the baſe of the curve or intercepted portion of the aſymptote above-mentioned, and the height of which would repreſent the uniform force of gravity. Hence the ſquare of the velocity of the ball reſulting from gravity is given, being the velocity it would acquire from a height equal to the ſpace through which the powder accelerates it; and the proportion between the hyperbola and the rectangle is given from the analogy between the hyperbolic ſpaces and logarithms; therefore the velocity of the ball ariſing from the action of the fired gunpowder will be given.

Mr. Robins has alſo given us an ingenious way of determining, by experiments, the velocity which any ball moves with at any diſtance of the piece it is diſcharged from.

This may be effected by means of a pendulum made of iron, having a broad part at bottom, covered with a thick piece of wood, which is faſtened to the iron by ſcrews: then having three poles joined together by their tops, and ſpreading at bottom, ſuch as are vulgarly uſed in weighing and lifting heavy bodies, and called by workmen triangles; on two of theſe poles, towards their tops, are ſcrewed on ſockets, on which the pendulum is hung by means of a croſs piece, which becomes its axis of ſuſpenſion, and on which it ought to vibrate with great freedom. Something lower than the bottom of the pendulum there ſhould be a brace, joining the two poles to which the pendulum is ſuſpended; and to this brace there

there is faſtened a contrivance made with two edges of ſteel, ſomething in the manner of a drawing-pen; the ſtrength with which theſe edges preſs on each other being diminiſhed or increaſed at pleaſure, by means of a ſcrew. To the bottom of the pendulum ſhould be faſtened a narrow ribbon, which, paſſing between the ſteel edges, may hang looſely down by means of an opening cut in the lower piece of ſteel.

The inſtrument being thus fitted, if the weight of the pendulum, the reſpective diſtances of its center of gravity, and of its center of oſcillation, from its axis of ſuſpenſion, be known, it may from thence be found, what motion will be communicated to this pendulum by the percuſſion of a body of a known weight moving with a known degree of velocity, and ſtriking it in a given point; that is, if the pendulum be ſuppoſed at reſt before the percuſſion, it will be known what vibration it ought to make in conſequence of ſuch a blow; and if the pendulum, being at reſt, is ſtruck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the ſtriking body may from thence be determined.

Now the extent of the vibration, made by the pendulum, may be meaſured by the ribbon: for if the preſſure of the ſteel edges on the ribbon be regulated by the ſcrew, ſo as to be free and eaſy, though with ſome minute reſiſtance to hinder its ſlipping of itſelf: then, ſetting the pendulum at reſt, let the part of the ribbon between the pendulum and the ſteel edges be drawn ſtraight, but not ſtrained, and fixing a pin in the part of the ribbon contiguous to the edges, the pendulum, ſwinging back by the impulſe of the ball, will draw out the ribbon to the juſt extent of its vibration, which will be determined by the interval on the ribbon between the edges and the place of the pin.

The computation by which the velocity of the ball is determined from the vibration of the pendulum after the ſtroke, is founded on this principle of mechanics: that if a body in motion ſtrikes on another at reſt, and they are not ſeparated after the ſtroke, but move on with one common motion, then that common motion is equal to the motion with which the firſt body moved before the ſtroke: whence, if that common motion and the maſſes of the two bodies are known, the motion of the firſt body before the ſtroke is thence determined. On this principle it follows, that the velocity of a bullet may be diminiſhed in any given ratio, by its being made to impinge on a body of weight properly proportioned to it; and hereby the moſt violent motions, which would otherwiſe eſcape our examination, are eaſily determined by the retarded motions which have a given relation to them.

It is to be obſerved, that the length to which the ribbon is drawn, is always near the chord of the arch deſcribed by the aſcent; it being ſo placed, as to differ inſenſibly from thoſe chords which moſt frequently occur; and theſe chords are known to be in the proportion of the velocities of the pendulum acquired from the ſtroke. Hence it follows, that the proportion between the lengths of the ribbon, drawn out at different times, will be the ſame with that of the velocities of the impinging bullets.

Now, from the computations delivered by Mr. Robins, it appears, that the velocity of the bullet was 1641 feet in one ſecond of time, when the chord of the arch deſcribed by the aſcent of the pendulum, in conſequence of the blow, was 17 $\frac{1}{4}$ inches. Therefore, by the proportion of any other lengths of ribbon drawn out, by any percuſſion, to 17 $\frac{1}{4}$, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in one ſecond, will be determined.

GUN-POWDER, a compoſition of ſalt-petre, ſulphur, and charcoal, well mixed together and granulated; which eaſily takes fire, and expands with amazing force.

The invention of this compoſition is aſcribed by Polydore Virgil to a chemiſt, who having accidentally put the ingredients above-mentioned into a mortar, and covered it over with a ſtone, it happened to take fire, and threw off the ſtone. Thevel ſays that this chemiſt was one Conſtantine Anelzen, a monk of Friburg; but Belleforet and others aſſert it to be Bertholdus Schwartz: at leaſt it is affirmed that he firſt taught the uſe of gun-powder to the Venetians, in the year 1380. Peter Mexia however contradicts this account, by ſhewing it to have been uſed by Alphonſus XI. king of Caſtile, in the year 1342. Ducange adds, that there is mention made of this powder in the regiſters of the chambers of accounts of France, ſo early as the year 1338; and our countryman, Friar Bacon, expreſsly mentions the compoſition, in his treatiſe *De nullitate Magiæ*, publiſhed at Oxford in the year 1216.

Method of making GUN-POWDER. The following recipe for making gun-powder is taken from Dr. Shaw's Chemical Lectures.

Take four ounces of refined ſalt-petre, an ounce of brimſtone, and ſix drams of charcoal; reduce theſe to a fine powder, and continue beating them for ſome time in a ſtone mortar, with a wooden peſtle, wetting the mixture between whiles with water, ſo as to form the whole into an uniform paſte, which is reduced to grains, by paſſing it through a white ſieve for the purpoſe; and in this form, being carefully dried, it becomes the common gun-powder.

For greater quantities, mills are uſually provided, by means of which more work may be performed in one day than a man can do in a hundred. See MILL.

The nitre or ſalt-petre is refined thus: diſſolve four pounds of rough nitre as it comes to us from the Indies, by boiling it in as much water as will commodiouſly ſuffice for that purpoſe; then let it ſhoot for two or three days in a covered veſſel of earth, with ſticks laid acroſs for the cryſtals to adhere to. Theſe cryſtals being taken out, are drained and dried in the open air.

In order to reduce this ſalt to powder, they diſſolve a large quantity of it in as ſmall a proportion of water as poſſible; then keep it conſtantly ſtirring over the fire, till the water exhales, and a white dry powder is left behind. See NITRE.

In order to purify the brimſtone employed, they diſſolve it with a very gentle heat; then ſcum and paſs it through a double ſtrainer. If the brimſtone ſhould happen to take fire in the melting, they have an iron cover that fits on cloſe to the melting veſſel, and damps the flame. The brimſtone is judged to be ſufficiently refined if it melts without yielding any fetid odour between two hot iron plates into a kind of red ſubſtance.

The coal for the making of gun-powder is either that of willow, or hazel, well charred in the uſual manner, and reduced to powder: and thus the ingredients are prepared for making this commodity; but as theſe ingredients require to be intimately mixed, and as there would be danger of their firing if beat in a dry form, the method is to keep them continually moiſt, either with water, urine, or a ſolution of ſal ammoniac: they continue thus ſtamping them together for twenty-four hours, after which the maſs is fit for corning and drying in the ſun, or otherwiſe, ſo as ſedulouſly to prevent its firing.

Different kinds of GUN-POWDER. The three ingredients of gun-powder are mixed in various proportions, according as the powder is intended for muſquets, great guns, or mortars; through theſe proportions ſeem not to be perfectly adjuſted, or ſettled by competent experience.

Semienowitz for mortars, directs 100 ℔ of ſalt-petre, 25 ℔ of ſulphur, and as many of charcoal; for great guns, 100 ℔ of ſalt-petre, 15 ℔ of ſulphur, and 18 ℔ of charcoal; for muſquets and piſtols 100 ℔ of ſalt-petre, 8 ℔ of ſulphur, and 10 ℔ of charcoal. Miethius extols the proportion of 1 ℔ of ſalt-petre to three ounces of charcoal, and two or two and a quarter of ſulphur; than which, he affirms, no gun powder can poſſibly be ſtronger. He adds, that the uſual practice of making the gun-powder weaker for mortars than guns, is without any foundation, and renders the expence needleſsly much greater: for whereas to load a large mortar, 24 ℔ of common powder is required, and conſequently to load it ten times 240 ℔, he ſhews by calculation, that the ſame effect would be had by 150 ℔ of the ſtrong powder.

To increaſe the ſtrength of powder, Dr. Shaw thinks it proper to make the grains conſiderably large, and to have it well ſifted from the ſmall duſt. We ſee that gun-powder, reduced to duſt, has little exploſive force; but

when the grains are large, the flame of one grain has a ready paſſage to another, ſo that the whole parcel may thus take fire nearly at the ſame time, otherwiſe much force may be loſt, or many of the grains go away as ſhot unfired.

Method of trying and examining GUN-POWDER. There are two general methods of examining gun-powder; one with regard to purity, the other with regard to its ſtrength. Its purity is known by laying two or three little heaps near each other upon white paper, and firing one of them; for if this takes fire readily, and the ſmoke riſes upright, without leaving any droſs, or feculent matter behind, and without burning the paper, or firing the other heaps; it is eſteemed a ſign that the ſulphur and nitre were well purified, that the coal was good, and that the three ingredients were thoroughly incorporated together; but if the other heaps alſo take fire at the ſame time, it is preſumed that either common ſalt was mixed with the nitre, or that the coal was not well ground, or the whole maſs not well beat, and mixed together; and if either the nitre or ſulphur be not well purified, the paper will be black or ſpotted.

In order to try the ſtrength of gun-powder, there are two kinds of inſtruments in uſe; but neither of them appear more exact than the common method of trying to what diſtance a certain weight of powder will throw a ball from a muſket.

There has been much talk of a white powder, which, if it anſwered the character given it, might be a dangerous compoſition: for they pretend that this white powder will throw a ball as far as the black, yet without making a report; but none of the white powder we have ſeen, ſays Dr. Shaw, anſwers to this character; being, as we apprehend, commonly made either with touchwood or camphor, inſtead of coal.

Obſervations on the Force of GUN-POWDER. Gun-powder fired either in vacuum, or in air, produces by its exploſion a permanent elaſtic fluid: for if a red-hot iron be included in a receiver, after being exhauſted, and gun-powder be let fall on the iron, the powder will take fire, and the mercurial gage will ſuddenly deſcend upon the exploſion; and though it immediately aſcends again, yet it will never riſe to the height it firſt ſtood at, but will continue depreſſed by a ſpace proportioned to the quantity of gun-powder which was let fall on the iron.

The ſame production likewiſe takes place, when gun-powder is fired in the air: for if a ſmall quantity of powder be placed in the upper-part of a glaſs tube, and the lower part of the tube be immerged in water, and the water be made to riſe ſo near the top, that only a ſmall portion of air is left in that part where the gun-powder is placed: if in this ſituation the communication of the upper-part of the tube with the external air be cloſed, and the powder be fired, which will eaſily be done by a burning glaſs, the water will in this experiment deſcend upon the exploſion, as the quickſilver did in the laſt; and will always continue depreſſed below the place at which it ſtood before the exploſion; and the quantity of this depreſſion will be greater, if the quantity of powder be increaſed, or the diameter of the tube be diminiſhed. From whence it is proved, that as well in air as in a vacuum, the exploſion of fired powder produces a permanent elaſtic fluid. It alſo appears from experiment, that the elaſticity or preſſure of the fluid produced by the firing of gun-powder, is, *cæteris paribus*, directly as its denſity. This follows from hence, that if in the ſame receiver a double quantity of powder be let fall, the mercury will ſubſide twice as much as in the firing of a ſingle quantity.

To determine the elaſticity and quantity of this elaſtic fluid, produced from the exploſion of a given quantity of gun-powder, Mr. Robins premiſes, that the elaſticity of this fluid increaſes by heat, and diminiſhes by cold in the ſame manner as that of the air; and that the denſity of this fluid, and conſequently its weight, is the ſame with the weight of an equal bulk of air having the ſame elaſticity, and the ſame temperature. From theſe principles, and from his experiments, for a detail of which we muſt refer the reader to his New Principles of Gunnery, in Scholium to Prop. II. he concludes, that the fluid produced by the firing of gun-powder will be $\frac{1}{100}$ of the weight of the gun-powder, and the ratio of the reſpective bulks of the powder, and the fluid produced from it, will be in round numbers 1 to 244.

Hence we are certain, that any quantity of powder fired in any confined ſpace, which it adequately fills, exerts, at the inſtant of its exploſion, againſt the ſides of the veſſel containing it, and the bodies it impels before it, a force at leaſt 244 times greater than the elaſticity of common air; or, which is the ſame thing, than the preſſure of the atmoſphere; and this without conſidering the great addition which this force will receive from the violent degree of heat with which it is endued at that time, the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elaſticity of the air is augmented when heated to the extremeſt heat of red-hot iron, in the proportion of 796 to 194 $\frac{1}{3}$, and ſuppoſing that the flame of fired gun-powder is not leſs hot than red-hot iron, and the elaſticity of the air, and conſequently of the fluid, generated by the exploſion, being augmented by the extremity of this heat in the ratio of 796 to 194 $\frac{1}{3}$, it follows, that if 244 be augmented in this ratio, the reſulting number, which is 999 $\frac{1}{3}$, will determine how many times the elaſticity of the flame of fired powder exceeds the elaſticity of common air, ſuppoſing it to be confined in the ſame ſpace which the powder filled before it was fired.

Hence then the abſolute quantity of the preſſure exerted by gun-powder, at the moment of its exploſion, may be aſſigned: for ſince the fluid then generated has an elaſticity of 999 $\frac{1}{3}$, or in round numbers 1000 times greater than common air; and ſince common air by its elaſticity exerts a preſſure on any given ſurface equal to the weight of the incumbent atmoſphere, with which it is in equilibrio, the preſſure exerted by fired powder, before it has dilated itſelf, is 1000 times greater than the preſſure of the atmoſphere; and conſequently the quantity of this force on a ſurface of an inch ſquare, amounts to above ſix tun weight, which force however diminiſhes as the fluid dilates itſelf. The variations of the denſity of the atmoſphere does not any way alter the action of powder by any experiment that can be made. But the moiſture of the air has a very great influence on the force of it; for that quantity which in a dry ſeaſon would communicate to a bullet a velocity of 1700 feet in one ſecond, will not in damp weather communicate a velocity of more than 12 or 1300 feet in a ſecond, or even leſs, if the powder be bad and negligently kept.

The velocity of expanſion of the flame of gun-powder when fired in a piece of artillery, without either bullet, or any other body before it, is prodigious. By the experiments of Mr. Robins, it ſeems this velocity cannot be much leſs than 7000 feet in a ſecond. This, however, muſt be underſtood of the moſt active part of the flame: for as, as was obſerved before, the elaſtic fluid in which the activity of gun-powder conſiſts, is only $\frac{1}{100}$ of the ſubſtance of the powder, the remaining $\frac{99}{100}$ will in the exploſion be mixed with the elaſtic part, and will by its weight retard the activity of the exploſion; and yet they will be ſo compleatly united as to move with uncommon motion; but the unelaſtic part will be leſs accelerated than the reſt, and ſome of it will not even be carried out of the barrel, as appears by the conſiderable quantity of unctuous matter which adheres to the inſide of all fire-arms, after they have been uſed. Theſe inequalities in the expanſive motion of the flame render it impracticable to determine its velocity, otherwiſe than from experiments.

To recover damaged GUN-POWDER. The method of the powder-merchants is this; they put part of the powder on a ſail-cloth, to which they add an equal weight of what is really good, and with a ſhovel mingle it well together, dry it in the ſun, and barrel it up, keeping it in a dry and proper place. Others again, if it be very bad, reſtore it by moiſtening it with vinegar, water, urine, or brandy: then they beat it fine, ſearce it, and to every pound of powder add an ounce, an ounce and a half, or two ounces, according as it is decayed, of melted ſalt-petre. Afterwards, theſe ingredients are to be moiſtened and mixed well, ſo that nothing can be diſcerned in the compoſition, which may be known by cutting the maſs; and then they granulate it as aforeſaid. In caſe the powder be in a manner quite ſpoiled, the only way is to extract the ſalt-petre with water, according to the

the uſual manner, by boiling, filtrating, evaporating, and cryſtallizing; and then with freſh ſulphur and charcoal to make it up a-new again. In regard to the medical virtues of gun-powder, Boerhaave informs us, that the flame of it affords a very healthy fume in the height of the plague, becauſe the exploſive acid vapour of nitre and ſulphur corrects the air; and that the ſame vapour, if received in a ſmall cloſe pent-up place, kills inſects.

GUN-SHOT-WOUNDS, thoſe made by ſhot, bullets, &c. ſhot from ſome ſpecies of fire-arms.

Theſe wounds are attended with much worſe conſequences than wounds made with cutting inſtruments; for the parts are more ſhattered and torn, eſpecially when the ſhot falls upon the joints, bones, or any conſiderable part. Wounds of this kind have an eſchar formed upon them, and are therefore attended with little or no hæmorrhage at firſt, unleſs ſome very conſiderable veſſel happens to be wounded; but as ſoon as this eſchar falls off, the hæmorrhage is ſometimes ſo violent, as to endanger the life of the patient, unleſs the immediate aſſiſtance of a ſurgeon can be procured.

There being for the five or ſix firſt days little or no diſcharge of matter from theſe wounds, it is no wonder that gun-ſhot wounds exceed all others in the violence of their ſymptoms, ſuch as inflammation, pain, gangrene, &c.

The eſchar formed upon theſe wounds is not occaſioned ſo much by the heat of the bullets, as by the rapidity with which they deſtroy the parts; and the violence of the ſymptoms is chiefly owing to this manner of wounding. Nor is there any thing poiſonous in theſe wounds, as ſome have imagined; for nothing poiſonous enters the compoſition of either the powder or the ball.

Gun-ſhot wounds are ſome deeper than others; in ſome the muſcular parts alone are hurt; in others the veſſels, bones, or viſcera, are wounded. Sometimes the ball paſſes clear through; ſometimes it remains fixed in the wound, and often carries part of the wadding, or the patient's clothes with it. From the difference of theſe circumſtances very different ſymptoms muſt ariſe.

Gun-ſhot wounds in the cranium, even the ſlighteſt of them, are attended with very great danger, and frequently bring on terrible ſymptoms, from the concuſſion they occaſion in the internal parts; ſo that it is ſurprizing to ſee how ſmall an external wound upon this part, will bring on death, if not prevented by the trepan. Internal wounds of this ſort are alſo extremely dangerous; but, unleſs ſome large veſſel be wounded, they are frequently cured.

When they are inflicted on the bones or joints, they are attended with very bad ſymptoms; for in this caſe it is next to impoſſible to eſcape inflammation, gangrene, caries, and dangerous fiſtulæ, which either require amputation of the limb, or leave it without ſenſe or motion.

If any parts of the clothes, wadding, or any other extraneous body be forced into the wound, it muſt be removed before you can attempt to heal the wound; and the ſame caution is to be obſerved in regard to any ſplinters of bone: when theſe are removed, the hæmorrhage is to be ſtopped, then ſuppuration is to be promoted, and new fleſh encouraged, and care taken to procure an even cicatrix.

Extraneous bodies are much eaſieſt to be removed at firſt; for after ſome delay the tumor, and inflammation of the part, render it difficult and painful: beſides, the bullets will by degrees work themſelves deeper, and be buried under the muſcles, which will occaſion fiſtulæ, rigidity of the limb, and other inconveniencies. In extracting balls that lie deep, you muſt take great care not to lay hold of blood-veſſels or nerves; which accident will be beſt avoided, by introducing the forceps ſhut, and not opening them till you feel the ball.

Sometimes the orifices of theſe wounds are ſo narrow, that it is impoſſible to come at the body you are to extract, without making a larger opening; this then muſt be done on the moſt convenient ſide, always obſerving that no nerve, blood-veſſel, tendon, or ligament, lies in the way. When the parts are very much inflamed and ſwelled, an opening of this kind is frequently of ſervice; for by this means the obſtructed blood is diſcharged, and the bad conſequences of the inflammation are prevented. When the extraction of the ball is attempted, the patient muſt be put into the ſame poſture and ſituation that he was in when he received the wound. When the ball has penetrated ſo deep, that it may be eaſily felt with the finger on the oppoſite ſide, it is ſometimes better to make an inciſion there, and take it out in that place, than to attempt the getting it back the other way. If the wound cannot ſafely be enlarged, nor the ball extracted at firſt, without great pain and danger, it muſt be left in the wound, either till the pain is abated, or the wound is ſo enlarged by ſuppuration, that it either can work itſelf out, or be extracted with leſs danger. On the other hand, all other extraneous bodies are inſtantly to be removed, where there is danger of their bringing on pain, inflammation, and convulſions, by being left behind. If a ball has paſſed into the cavities of the body, it is beſt not to attempt to extract it, but to heal the wound, leaving it there. Perſons have carried a ball in them thus, for many years, without inconvenience; and, at one time or other, it frequently happens that it will work itſelf into ſome part of the body, out of which it may be extracted with ſafety.

If a large artery is wounded by the ball, either in the arms or legs, which will be known by the loſs of blood, the tourniquet muſt be applied, and, the blood being ſtopped, the veſſel muſt be taken up by a crooked needle; but, if this cannot be done, or little hopes of a cure appear from future dreſſings, it will be prudent to take off the limb juſt above the wound. When wounds of this kind have been well cleaned, and the blood ſtopped, the firſt intention is to uſe the utmoſt endeavours to prevent, or aſſuage the tumor and inflammation. The wound ſhould be dreſſed with lint dipped in warm ſpirits of wine, and covered with a compreſs wetted with the ſame liquor; or with camphorated ſpirits of wine, either alone, or diluted with lime water. Having done this, the next intention is to forward the ſuppuration of the bruiſed and torn parts; to which end, it is cuſtomary to uſe the common digeſtive made of turpentine diſſolved in the yolk of an egg, or a mixture of baſilicon and Arcæus's liniment, ſoftened with ſpirits of wine and oil; and, where there is a very great corruption of the parts, a little myrrh and aloes are to be added, as alſo Venice treacle, the brown ointment, and, where the occaſion requires it, and the nerves do not lie bare, a little of the red precipitate.

In deep wounds, where the ball has gone quite through, a ſkein of thread being drawn through the eye of a blunt needle, and well ſaturated with the digeſtive ointment, is to be paſſed through the wound in the manner of a ſeton, and kept there till the wound is found in a condition to heal, and then the common methods are purſued to heal and cicatrize. *Heiſter's Surgery.*

GUNTER's-LINE, called alſo the *Line of Numbers*, and the *Line of Lines*, is a graduated line uſually placed upon ſcales, ſectors, &c. ſo called from Edmund Gunter, its inventor.

This line is no other than a logarithmic ſcale of proportionals, wherein the diſtance between each diviſion is equal to the number of mean proportionals contained between the two terms, in ſuch parts as the diſtance between 1 and 10 is 10000, &c. Wherefore,

If the diſtance betwixt 1 and 10 upon the ſcale be made equal to 10000, &c. equal parts, and .954, &c. the logarithm of 9 of the ſame parts, be ſet off from 1 to 9, it will give the diviſion ſtanding againſt the number 9. In like manner, if .903, .845, .778, which are the logarithms of 8, 7, and 6, of the ſame equal parts, be ſet off from 1 to 8, 7, and 6, they will give the diviſions anſwering to the numbers 8, 7, and 6, upon the line. And after the ſame manner may the whole line be divided.

This line has been contrived various ways, for the advantage of having it as long as poſſible. It was firſt placed, by its inventor Edmund Gunter, on a two feet ſcale. After this, Wingate doubled the line, in order to render it ſuſceptible of working right on or a-croſs. Then, the learned Oughtred projected it in a circle, and alſo made it to ſlide: and, laſtly, it was projected in a kind of ſpiral, by Brown.

But the method of uſing or applying it in all is not very different. In Gunter's and Wingate's projection, com-

mon compaſſes are uſed; in Oughtred's and Brown's flat compaſſes, or an opening index; and in the ſliding rule no compaſſes at all, the ſlider ſupplying the place of the compaſſes.

Deſcription of GUNTER's *Line.* This line is uſually divided into an hundred parts, every tenth whereof is numbered, beginning with 1, and ending with 10. So that, if the firſt great diviſion 1 repreſent one tenth of any integer or whole number, the next 2 will repreſent 2 tenths; 3, three tenths, &c. and the intermediate diviſions ſo many 100th parts of the ſame integer. Or, if theſe ſubdiviſions repreſent 10 integers, then each of the larger diviſions will repreſent 100, and the whole line will be 1000. In like manner, it may be extended to 10000 by making each ſubdiviſion 100. Hence, it is eaſy to conceive, that any number whatſoever may be found upon the rule, by increaſing or decreaſing the large diviſions, and, conſequently, this ſingle line will repreſent the whole table of logarithms.

Uſe of GUNTER's *Line.*—1. One number being given to be multiplied by another, to find their product.

Suppoſe the numbers given were 8 and 4, to find their product.—Extend the compaſſes from 1 to 4, and that extent laid from 8, the ſame way, will reach to 32, the product required. Or, if you work by the ſliding-rule, ſet 1, at the beginning of the ſliding-piece, againſt 4 on the upper or fixed piece; and againſt 4 on the ſlider ſtands 32, on the upper or fixed piece, which is the product required. Whence it is abundantly evident, that the ſliding-piece performs the office of the compaſſes, and therefore, when the method of ſolving any problem by the compaſſes is underſtood, there will be no difficulty of ſolving the ſame by the ſliding-rule.

2. One number being given to be divided by another, to find the quotient.—Suppoſe it were required to divide 64 by 4. Extend the compaſſes from 4 to 1, and the ſame extent, laid the ſame way, will reach from 64 to 16, the quotient required.

3. Three numbers being given to find a fourth in direct proportion.—Let the numbers given be 7, 22, and 14. Extend the compaſſes from 7 to 22, which extent, laid the ſame way, will reach from 14 to 44, the fourth proportional required.

4. To find a mean proportional between 2 given numbers.—Biſſect the diſtance between the two given numbers, and the point of biſſection will fall on the proportional ſought. Thus, if the numbers given be 32 and 8, the middle point between them will be 16, which is the mean proportional required.

5. To extract the ſquare root of any number.—Biſſect the diſtance between 1 on the line, and the point repreſenting the given number; the half whereof being laid from one will give the root required. Thus the ſquare root of 9 will be found to be 3, of 81, 9, &c. The reaſon of theſe operations will be eaſily conceived, by conſidering the nature of logarithms; for, as we have already obſerved, this line is no other than a projection of the table of logarithms, and, conſequently, whatever is ſaid of the latter may juſtly be applied to the former. See LOGARITHMS.

GUNTER's-QUADRANT, one made of wood, braſs, &c. containing a kind of ſtereographic projection of the ſphere on the plane of the equinoctial; the eye being ſuppoſed placed in one of the poles.

Beſides the uſe of this quadrant in finding heights and diſtances, it ſerves alſo to find the hour of the day, the ſun's azimuth, and other problems of the globe. See the article *Gunter's* QUADRANT.

GUNTER's SCALE, called by navigators ſimply the Gunter, is a large ſcale, generally two feet long, and about an inch and a half broad, with artificial lines delineated on it, of great uſe in ſolving queſtions in trigonometry, navigation, &c.

The line of numbers on theſe ſcales conſiſts of two equal lengths, commonly called two radii; the firſt containing the logarithms of numbers from 10 to 100; and in the ſecond are inſerted thoſe between 100 and 1000, or ſuch of them as can conveniently be introduced.

Theſe diviſions are taken from a ſcale of equal parts; ſuch, that 100 make the length of one radius; and from this ſcale the diviſions for the ſines, tangents, and verſed ſines, are alſo taken. Now, from this conſtruction of the line of numbers, it is plain, that, as the numbers in one radius exceed thoſe in the other, by one place in the ſcale of numeration, therefore the differences of their indices muſt alſo be unity: ſo that ſuch numbers only, whoſe index differs by 1, can be eſtimated in a length of two radii; but in a length of three radii, numbers, whoſe indices differ by 2, may be read; and a difference of 3 may be reckoned in a length of 4 radii, &c. The tables of logarithmic ſines, tangents, ſecants, and verſed ſines, are generally computed for a circle, whoſe radius is 10,000,000: therefore,

In the ſines, the index 9 belongs to all between	90	0	0	and	5	44	36
The index 8	5	44	36	and	0	34	23
The index 7 to all between	0	34	23	and	0	3	27
6	0	3	27	and	0	0	21 &c.
In the tangents, the index 9 belongs to all between	45	0	and	5	42	10	

And the indices, 8, 7, 6, &c. fall as in the ſines.

In the verſed ſines, the index 10 belongs to all between	180	0	and	90	0
9 belongs to all between	90	0	and	25	51
8	25	51	and	8	7
7	8	7	and	2	34
6	2	4	and	0	45 &c.

Now, as the length of the Gunter's ſcale admits of no more than two radii, or of ſuch numbers only, whoſe index differs by unity; therefore, within this length, no more of the ſines, tangents, or verſed ſines, can be introduced, than thoſe whoſe index differs by unity: and as not only the greateſt number among the ſines and tangents, but alſo thoſe more generally wanted, have the indices 9 and 8 differing by unity; therefore all the ſines from 90° to 0° 34′, and all the tangents from 45° to 0° 34′, are thoſe only, which are put on theſe ſcales; the diviſions anſwering to the leſſer ſines and tangents being omitted for want of room. And this is the reaſon why the ſine of 90°, and the tangent of 45°, are limited by the ſame termination as the ſecond radius on the line of numbers.

To conſtruct the Line of logarithmic Sines on GUNTER's *Scale.*—From the ſcale of equal parts, take the numbers expreſſing the arithmetical complements of the log-ſines of the ſucceſſive degrees, and parts of degrees, intended to be put on the ſcale, deſcending orderly from 90°; then theſe diſtances, ſucceſſively laid from the mark repreſenting 90° at the right-hand end of the ſcale, will give the ſeveral diviſions of a ſcale of logarithmic ſines.

For the ends of any ſcale being aſſigned, the progreſſive diviſions of that ſcale are laid thereon from that end, which repreſents the beginning of the progreſſion; or the ſame diviſions may be laid from the other end, by taking the complements of the terms to the whole length of the ſcale.

Conſequently the arithmetical complements of the ſines are to be laid from the diviſion repreſenting 90 degrees.

To conſtruct the Line of logarithmic Tangents on GUNTER's *Scale.*—Theſe are laid down in the ſame manner, and for the ſame reaſons, that the ſines were; the tangent of 45° ſtanding againſt the ſine of 90°.

The diviſions for the tangents above 45° are reckoned on the ſame line from 45° towards the left hand; or any tangent and its cotangent are expreſſed by the ſame diviſion.

Thus one mark ſerves for 40° and 50°, and the diviſion at 30° ſerves alſo for 60°; that at 20° ſerves for 70°, &c. and the like is to be underſtood for the intermediate diviſions.

For as the tangent of an arc is to a radius;

So is radius to the cotangent of that arc.

Therefore the tangent is equal to the ſquare of radius divided by the co-tangent.

And the co-tangent is equal to the ſquare of radius divided by the tangent.

Now, the radius being unity, its ſquare is alſo unity.

Therefore the tangent and co-tangent of any arc are the reciprocals one of the other.

But the reciprocals of numbers are correlatives to the arithmetical complements of their logarithms.

Therefore the logarithms of a tangent and its co-tangent are arithmetical complements one of the other, and conſequently will fall at equal diſtances from 45 degrees.

Therefore, in the line of logarithmic tangents, the diviſions to degrees under 45 ſerve alſo for thoſe above, both being equally diſtant from 45 degrees.

To conſtruct the Line of logarithmic verſed Sines on GUNTER's *Scale.*—As the greateſt number of degrees will fall within the limits of the ſcale by beginning at 18°, therefore the termination of this line is at 18°, which is put againſt 90° on the ſines: and although the numbers annexed to the diviſions increaſe in the order from right to left, yet they are only the ſupplements of the verſed ſines themſelves.

Now ſubtract the logarithmic verſed ſines of ſuch degrees and parts of degrees as are intended to be put on the ſcale, from the logarithm verſed ſine of 180°; then the remainder taken from the foreſaid ſcale of equal parts, and laid ſucceſſively from the termination of this line, will give the ſeveral diviſions ſought.

The following Table to every 10 degrees was conſtructed in the foregoing manner, and are the numbers to be taken from the ſcale of equal parts, for the degrees they ſtand againſt.

Deg.	Supplements of Verſed Sines.	Deg.	Supplements of Verſed Sines.	Deg.	Supplements of Verſed Sines.
180	0,00000	120	0,12494	60	0,60206
170	0,00331	110	0,17327	50	0,74810
160	0,01330	100	0,23149	40	0,93190
150	0,03011	90	0,30103	30	1,17401
140	0,05402	80	0,38387	20	1,52066
130	0,08545	70	0,48282	10	2,21941

From this table it appears, that the leaſt verſed ſine which can be introduced within the length of a double radius, falls between 10° and 20°, where the index changes from 1 to 2; which will happen about 11° 28′.

If a table of logarithm verſed ſines to 180° are wanting, they are eaſily made by the following rule:

"Take the logarithm ſine of 30 degrees from twice the logarithm ſine of (N) any number of degrees; the remainder is the logarithm verſed ſine of (2 N, or) twice thoſe degrees."

For it is a well known geometrical property, that the ſine of any arc (A) is a mean proportional between radius (R) and half the verſed ſine of twice that arc.

Therefore, putting v for the verſed ſine, and s for the ſine;

The $v\,2\,A = \left(\frac{2\,s\,s\,A}{R} = s\,s\,A \times \frac{2}{R} = s\,s\,A \times \frac{2}{10} =\right)$ $s\,s\,A \times \frac{1}{5}$; radius being 10.

Or the log. $v\,2\,A = 2$ log. $s\,A -$ log. 5.

But, when radius is 10, the ſine of 30° is 5.

Therefore the log. $v\,2\,A = 2$ log. $s\,A -$ log. ſine of 30°.

Moſt of the writers on this ſubject give the following rule for laying down the diviſions of this line:

"From the line of logarithmic ſines, take the diſtance between 90° and any arc; that diſtance being twice repeated, from the termination of the line of verſed ſines, will give the diviſion for twice the complement of that arc."

Thus the diſtance between 90° and 20° on the ſines twice repeated gives the verſed ſine of 140°; or twice 70°, the complement of 20°. For the diviſions to be laid on this line, are the differences between the logarithm verſed ſine of 180°, and the logarithm verſed ſines of the ſucceſſive arcs.

Now the difference between the logarithm verſed ſines of 180°, and of any arc 2 A, is log. ver. ſine 180 − 2 log. ſin. A + log. ſin. of 30°.

Or, 10,30103 + 9,69897 − twice log. ſin. of A.

Or, 20,00000 − twice logarithm ſine of A.

Or the arithmetical complement of twice log. ſine of A.

That is, the difference between the logarithm verſed ſine of 180°, and the logarithm verſed ſine of any arc, is equal to double the arithmetical complement of the logarithm ſine of half that arc, rejecting the indices.

But as the differences give the diviſions to the ſupplements of the real verſed ſines, therefore the arithmetical complement of the logarithm ſine of any arc, being doubled, will give the diſtance of the diviſion for the ſupplement of twice that arc on the line of verſed ſines.

Thus, for 70°, the logarithm ſine is 9,97299.

The arithmetical complement is 0,02701.

Its double is 0,05402.

Which is the number in the foregoing table ſtanding againſt 140°, and is the ſupplement verſed ſine of twice 70 degrees.

Now, as the arithmetical complement of the log. ſines of arcs are the diſtances on the line of ſines between 90°, and the diviſions to thoſe arcs; therefore the diſtances between 90° and any arc, being twice repeated, will give the diviſion of the ſupplemental verſed ſine to twice the co-ſine of that arc. *Phil. Tranſ.* Vol. XLIX.

GURNARD, in ichthyology, the Engliſh name of two ſpecies of trigla.

Theſe fiſhes, from their different colours, are called the grey and red gurnard. The grey gurnard has a bifid and ſpinoſe ſnout, with two ſpines at each eye. The red kind has likewiſe the roſtrum bifid, and the coverings of the gills ſtriated, and each of them armed with three ſpines. This laſt is a very remarkable ſpinoſe fiſh, which ſeldom exceeds a foot in length.

Both theſe fiſhes make a ſingular noiſe, when out of the water, not unlike the grunting of a hog; whence their Engliſh name.

GUSSET, in heraldry, is formed by a line drawn from the dexter or ſiniſter chief points, and falling down perpendicularly to the extreme baſe.

GUTTÆ, in architecture, are ornaments in form of little cones, in the platform of the Doric corniche, or architrave, underneath the triglyphs, repreſenting a ſort of drops or bells, uſually ſix in number. They are ſometimes called lachrymæ, companæ, or campanulæ.

GUTTÆ *Roſacea*, in medicine, denotes a red or pimpled face; a diſtemper which, though not always owing its original to hard drinking, is nevertheleſs moſt incident to tipplers of ſtrong beer, wines, ſpirits, &c.

As to the cure, beſides making a revulſion by bleeding, bliſtering, cupping, iſſues, &c. the diet ought to be moiſtening and cooling, as lettuce, purſlain, ſorrel, and ſpinach: the drink may be an emulſion of the cold ſeeds, milk and water, clarified whey, &c.

In the uſe, however, of this cooling regimen, great caution is neceſſary: for, if a perſon be taken off at once from his ſtrong liquors, and allowed nothing but whey, or milk and water, it may coſt him his life, by haſtening a ſudden decay of heat, palling his appetite, and bringing on a leucophlegmatia, or dropſy.

As for what concerns topics, much caution is likewiſe to be uſed. If there be only redneſs without pimples, and the diſeaſe recent, refrigerants and repellents take place: but, if puſtules appear, diſcutients muſt be mixed; and if theſe puſtules ſeem hard, and the diſeaſe be of long ſtanding, there may be reaſon for emollients to ripen and digeſt the tough and viſcid matter, which is afterwards to be let out.

If the diſeaſe be ſtubborn, and the tubercles grown hard, we are to begin with emollients, both fotus and ointment: ſuch are the decoction of mallows, vervain, Solomon's ſeal, and linſeed, alſo a cerate of ſperma-ceti, or Bates's white cerate. *James's Med. Dict.*

GUTTÆ *Serena*, barbarouſly ſo called by the Latin writers of the lower ages, which the Greeks term *αμαρυωσις*, in medicine, is a total blindneſs in the principal parts of the immediate organ of viſion, the eye ſtill continuing clear and ſeemingly unaffected.

This diſorder proceeds from various cauſes, of which the moſt common is an obſtruction gradually formed in the arteries of the retina by a ſizy blood; whereby the rays of light which ſhould depict the images of objects on the bottom of the eye, falling on theſe dilated blood-veſſels, produce no effect; whence the ſight is either diminiſhed, or entirely loſt, according to the degree of the obſtruction. Again, this diſeaſe is ſometimes owing to a palſy of the nerves of this ſame membrane, as it in ſome

meaſure

meaſure deſtroys their ſenſibility, whereby the impulſe of the corpuſcles of light on them is not ſufficient to make them tranſmit objects to the brain. In ſhort, I have obſerved that this ſpecies of blindneſs is alſo occaſioned by a preſſure on the optic nerves, either by the extravaſation of a glutinous humour, or by a hard tumor formed upon the place, where they paſs from their thalami into the eyes; whereby the paſſage of the animal ſpirits to the brain is totally intercepted. To preſerve this organ, which has ſo great a ſhare in making life uſeful and agreeable, we ought firſt to know how to diſtinguiſh the ſeveral ſpecies of the guttæ ſerena abovementioned, and their good and bad ſymptoms.

Wherefore a gradual dilatation of the pupil is a ſign of an obſtruction in the blood-veſſels by a ſizy blood. For this dilatation is the work of nature, in order that the detriment, which the ſight ſuffers by many of the rays of light falling on the ſmall arteries, inſtead of the nervous fibrillæ, may be compenſated by taking in a greater number of theſe rays. Hence the palſy of the nerves ſeldom or never occaſions this dilatation; but the preſſure on the optic nerve, either by an extravaſated humour, or a tumor gradually increaſing, is attended with a wider pupil for the aforeſaid reaſon.

Upon this principle it is that the ſecond and third ſpecies of the guttæ ſerena may be deemed incurable, as their cauſes are rendered inacceſſible by their very ſituation within the ſkull. Wherefore it is only the firſt ſpecies of this blindneſs that is curable; unleſs perhaps there may be ſome faint hopes of relieving that ſort which proceeds from a palſy of the retina, by antiparalytic medicines, of which the principal are aromatics, chalybeates, and the fœtid gums.

The cure, in general, conſiſts in removing the obſtruction of the veſſels, and correcting the lentor of the blood. Wherefore, firſt of all, blood is to be drawn both from the arm and the jugular, and to be repeated according to the degree of the diſeaſe. And it will be of uſe to apply cupping-glaſſes, with deep ſcarifications under the occiput, in order to let out blood this way from the lateral ſinuſes of the brain: then it will be neceſſary to give cathartics, eſpecially ſuch as purge groſs humours: but as nothing is found more powerful than quickſilver for inciding and expelling groſs and viſcid humours, it will be very proper to join calomel to other cathartics, or rather to take it by itſelf, and a few hours after it ſome gentle purgative.

And this method often ſucceeds when the diſeaſe is beginning or recent; but if it be of ſome ſtanding, it requires a plentiful ſalivation raiſed by mercurials taken inwardly in ſmall quantities, and at ſhort intervals. For mercury, by its extraordinary weight and diviſibility into extremely minute globules, penetrates into the inmoſt receſſes of the body, ſcours the glands and veſſels, and carries off the ſordes by the moſt convenient outlets. *Mead's Monita & Præcepta.*

GUTTERS, in architecture, a kind of canals in the roofs of houſes, ſerving to receive and carry off the rain.

Gutters, with reſpect to their poſition, are of two kinds: ſuch as come ſomething near a parallelism with the horizon; and ſuch as incline towards a vertical poſition to the horizon.

GUTTURAL, a term applied to letters or ſounds pronounced or formed as it were in the throat. There are four guttural letters in the Hebrew, viz. אהחע, which, for memory's ſake, are termed ahachah. See LETTER.

GUTTY, *Gutté*, in heraldry, a term uſed when any thing is changed or ſprinkled with drops.

In blazoning, the colour of the drops is to be named, as gutty of ſable, of gules, &c.

GUY, in naval affairs, a rope uſed to keep ſteady any weighty body which is hoiſted into, or lowered out of, a ſhip, or to prevent any thing from being ſhaken at ſea by the agitation of the ſhip on the waves.

GUZES, in heraldry, roundles of a ſanguine or murry colour. Theſe, from their bloody hue, are by ſome ſuppoſed to repreſent wounds.

GYMNASIARCH, *Gymnaſiarcha*, in antiquity, the maſter of a gymnaſium or place of exerciſe.

The word is Greek, γυμνασιαρχης, and derived from γυμνασιον, a place of exerciſe, and αρχων, a head or maſter.

This office was of great importance, as all the youth were truſted to this maſter's care to be formed to exerciſes of the body. He had three officers under him: the xyſtarch, who was maſter of the athletæ or wreſtlers: the gymnaſta, who had the direction of all the other exerciſes; as that they ſhould be performed in due time and properly; that the youth attempted nothing beyond their ſtrength, or injurious to their health: and the pædotriba, who taught the exerciſes mechanically without underſtanding their theory.

Under theſe were ſeveral ſubalterns or ſervants for the inſtruction of the youth.

GYMNASIUM, the place where the above exerciſes were performed, being a public edifice, under proper maſters.

The word is Greek, γυμνασιον, and is derived from γυμνος, naked, as they put off their clothes, the better to perform their exerciſes.

The Greeks were the firſt who had gymnaſia; particularly the Lacedæmonians, and afterwards the Athenians; from whom the Romans borrowed them.

At Athens were three of theſe places of exerciſe; the academy, where Plato taught; the lyceum, where Ariſtole read his lectures; and the cynoſarges, deſtined for the common people.

Vitruvius gives us the form of the ancient gymnaſia, lib. 5. c. 11. They were alſo called palæſtræ, from wreſtling, one of the moſt uſual exerciſes performed therein; and thermæ, as baths and bagnios made a principal part among the Romans. In Homer's time theſe exerciſes were performed always in drawers; but one Orſippus being entangled by their undoing, and ſo worſted, he threw them quite aſide in Olymp. XXXII. and this was afterwards followed by the reſt.

The gymnaſia had ſeveral apartments. M. Burette reckons the twelve following, as, 1. The exterior porticos, where the philoſophers and other ingenious men diſputed and read their lectures and other performances. 2. The ephebeum, where the youth learned their exerciſes in private. 3. The coryceum, apodyterion, or gymnaſterion, a wardrobe where they ſtripped either to bathe or exerciſe. 4. The elæotheſium, alipterion, or unctuarium, for the unctions before or after the bath, wreſtling, &c. 5. The coniſterium or coniſtra, where they covered themſelves with duſt or ſand to dry up the oil or ſweat. 6. The palæſtræ, where wreſtling, pugilate, pancratia, &c. were performed. 7. The ſphæriſterium or tennis-court for all exerciſes with balls. 8. Large unpaved alleys, between the porticos and walls, quite round the edifice. 9. The xyſti or porticos for the wreſtlers in winter or bad weather; and, 10. Thoſe for ſummer or fine weather, that were moſtly open, and others planted with trees. 11. The baths conſiſting of different apartments. 12. The ſtadium, a large ſemi-circular ſpace covered with ſand, and ſurrounded with ſeats for the ſpectators.

The exerciſes may be reduced to two claſſes, as depending on the action of the body alone, or requiring external inſtruments. The former were of two kinds, orcheſtrice and palæſtrice. Under orcheſtrice were compriſed dancing, cubiſtice or tumbling, ſpheriſtice or tennis, and all exerciſes with balls. Palæſtrice compriſed wreſtling, boxing, pancratia, hoplomachia, running, leaping, throwing the diſcus, the exerciſe of the javelin and hoop, or τροχος, which was an iron hoop, about ſix feet in diameter beſet with iron rings. It was driven with an iron-rod, and required ſtrength and dexterity to direct it.

There were alſo medicinal exerciſes, as walking, vociferation, and holding the breath.

The bodily exerciſes that depended on external agents were mounting the horſe, riding in a chaiſe, litter, or other wheel carriage, rocking, ſwinging, and likewiſe ſwimming. Hoffman reckons up thirty-five gymnaſtic exerciſes.

GYMNASTICS, the art of performing the ſeveral bodily exerciſes, as wreſtling, running, fencing, dancing, &c. See the article WRESTLING, &c.

The part of medicine which regulates the exerciſes of the

the body, whether for preſerving or reſtoring health, is alſo termed gymnaſtic.

GYMNOSOPHISTS, a ſect of philoſophers who cloathed themſelves no farther than modeſty required. There was ſome of theſe ſages in Africa; but the moſt celebrated clan of them was in India. The African gymnoſophiſts dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of houſe or cell. They did not form themſelves into ſocieties like thoſe of India, but each had his private retirement, where he ſtudied and performed his devotions by himſelf. If any perſon had killed another by chance, he applied to theſe ſages for abſolution, and ſubmitted to whatever penances they enjoined. They obſerved an extraordinary frugality, and lived only upon the fruits of the earth. Lucan aſcribes to theſe gymnoſophiſts ſeveral new diſcoveries in aſtronomy.

As to the Indian gymnoſophiſts, they dwelt in the woods, where they lived upon the wild products of the earth, and never drank wine, nor married. Some of them practiſed phyſic, and travelled from one place to another: theſe were particularly famous for their remedies againſt barrenneſs. Some of them, likewiſe, pretended to practiſe magic, and to foretel future events.

In general, the gymnoſophiſts were wiſe and learned men: their maxims and diſcourſes, recorded by hiſtorians, do not in the leaſt ſavour of a barbarous education, but are plainly the reſult of great ſenſe, and deep thought.

They kept up the dignity of their character to ſo high a degree, that it was never their cuſtom to wait upon any body, not even upon princes themſelves; for which reaſon Alexander, who would not condeſcend to viſit them in perſon, ſent ſome of his courtiers to them in order to ſatisfy his curioſity. Their way of educating their diſciples is very remarkable. Every day, at dinner, they examined them how they had ſpent the morning; and every one was obliged to ſhew, that he had diſcharged ſome good office, practiſed ſome virtue, or improved in ſome part of learning: if nothing of this appeared, he was ſent back without his dinner. They held a tranſmigration of ſouls; and it is probable that Pythagoras borrowed his doctrine from them.

GYMNOSPERMIA, in botany, a ſeries or ſub-diviſion of the didynamia claſs of plants; comprehending all thoſe with labiated flowers, without any pericarpium or capſule ſurrounding their ſeeds, which are only lodged in the baſe of the cup; whence the name gymnoſpermia. See the article DIDYNAMIA.

GYNÆCEUM, among the ancients, the apartment of the women, a ſeparate room in the inner part of the houſe, where they employed themſelves in ſpinning, weaving, and needle-work.

GYNANDRIA, in botany, a claſs of plants, in which the male and female parts of the flower are joined at their origin, the ſtamina or male parts of which grow to the piſtillum or female part, and not to the receptacle of the ſeed.

The word is formed of the Greek γυνη, female, and ανηρ, male.

Among the plants of this claſs are the paſſion-flower, birth-wort, &c.

The general character of this claſs of plants is very obvious; they are diſtinguiſhed at firſt ſight from all others, by the ſtamina being placed upon the ſtyle; or, in other words, the receptacle is elongated into the form of a ſtyle, and bears on it both the piſtil and ſtamina.

GYPSUM, or PLASTER-STONE, in natural hiſtory, a genus of foſſils naturally and eſſentially ſimple, not inflammable nor ſoluble in water, and compoſed of ſmall flat particles; which form bright, gloſſy, and in ſome degree tranſparent maſſes, not flexible or elaſtic, not giving fire with ſteel, nor fermenting with or being ſoluble in acid menſtrua, and very eaſily calcining the fire.

Of theſe gypſums, ſome are harder, others ſofter; and are of ſeveral colours, as white, grey, red, green, &c. ſometimes diſtinct, and ſometimes variouſly blended together.

The texture of all the gypſums being ultimately the ſame, it may be ſufficient to obſerve, that their origin is plainly from particles of a determinate nature and ſubſtance, and of a certain and invariable figure, an oblong, flat, and irregularly angular one. Theſe we ſometimes ſee, as indeed is moſt natural to them, diſpoſed without order or regularity, into looſe, complex, friable maſſes; at others, they are getting out of their native order, and emulating the ſtructure of other claſſes of bodies, of which they are indeed properly the baſis, and appearing ſomewhat in the figure of the fibrariæ; and at other times, of the foliaceous compoſite flakes of the ſelenitæ: the ſpecies which have theſe ſtructures, are truly varying from the gypſums into thoſe bodies they emulate; for the fibrariæ are only a peculiar arrangement of theſe very particles, and the ſelenitæ only more broad flakes of the ſame, like thoſe of the foliaceous talcs.

The gypſums are much uſed in plaſter, for ſtuccoing rooms, and caſting buſts and ſtatues.

GYPSUM STRIATUM, ſtriated plaſter-ſtone, the whitiſh, leſs gloſy tricheria, with ſhort thick filaments. See TRICHERIA.

H.

H A B

H E B

H, The eighth letter of the Engliſh alphabet, and ſixth conſonant.

It is in the old Greek alphabet, and is probably derived from the Phœnician Cheth ח, by putting a ſtroke acroſs the middle, inſtead of each end. It is formed by an effort of the larynx to modify the ſound of the following vowel, by a ſtrong exſpiration of the breath between the lips, cloſing with a gentle motion of the lower jaw to the upper, and the tongue nearly approaching the palate. Thus, the vowel *e* in *health*, *hero*, *heaven*, &c. is differently modified from what it is in the words *endive*, *eating*, *elect*, &c.

It is a conſonant of the guttural kind, as the throat concurs more to its formation than any other of the organs of ſpeech.

Menage diſtinguiſhes two kinds of *h*; the one an aſpirate, which is a conſonant; and the other a mute, which has no peculiar ſound diſtinct from that of the immediately following vowel or diphthong.

When the *h* is preceded by a *c*, both together often ſound like the Hebrew ש, with a point over the right horn, as *charity*, &c.

The *c h* in moſt words derived from the Greek, and expreſſed in that language by χ, is generally ſounded like a *k*, as *echo*, *chorus*, &c. though ſometimes ſoftened, as *Cherſoneſus*.

P h is pronounced like an *f*; as *phraſes*, *Philiſtines*, *phlegm*, &c. moſt of theſe words being of Greek, or Oriental original, proper names, &c. and wrote in Greek with a φ, and with a פ in the Hebrew.

H in ancient authors we meet with inſtead of *f*; particularly in the Spaniſh, where moſt of the words borrowed from the Latin, beginning with an *f*, take the *h* inſtead of it, as *hablari* for *fabulari*, *haba* for *faba*, &c.

The ſharp accent of the Greeks, which is the ſame with our *h*, is frequently changed for an *s*, as ἅλς, ſal, ἑπτὰ, ſeptem, &c.

Anciently *h* was put for *ch*: thus, of *Chlodovicus* was formed *Hludovicus*, as we find in the coins of the ninth and tenth centuries; in proceſs of time the ſecond of the *h*'s being much weakened, the *h* was entirely dropped, and was written *Ludovicus*.

The *h* is ſometimes found prefixed to the *c*, as *Hcarolus*, *hcalendæ*, &c. for *Carolus* and *calendæ*.

H alſo, among the ancients, denotes 200, according to the Monkiſh verſe.

H quoque ducentos per ſe deſignat habendos.

When a daſh was added at top, $\overline{H}$ ſignified 200,000.

HABBAKUK, or the prophecy of Habbakuk, a canonical book of the Old Teſtament.

There is no mention made in Scripture, either of the time when this prophet lived, or of the parents from whom he was deſcended; but according to the authors of the lives of the prophets, he was of the tribe of Simeon; and a native of Bethzacar. As he foreſaw the taking of Jeruſalem by Nebuchadnezzar, he fled to Oſtracin in Arabia, where he lived for ſome time; but after the Chaldæans had made themſelves maſters of Jeruſalem, and were on their return home, he returned into Judæa, where he employed himſelf in agriculture; but as he was carrying the reapers their dinner, he is ſaid to have been tranſported by an angel to Babylon, with what he had provided for his people in the field; which he ſet before Daniel, who was ſhut up in the lions den, and was tranſported back again to Judæa, where he died, before the end of the captivity.

He is reported to have been the author of ſeveral prophecies which are not extant; but thoſe that are indiſputably his, are contained in three chapters. In theſe the prophet complains very pathetically of the diſorders which he obſerved in the kingdom of Judæa. God reveals to him, that he would ſhortly puniſh them in a very terrible manner by the arms of the Chaldæans. He foretels the conqueſts of Nebuchadnezzar, his metamorphoſis, and death. He predicts, that the vaſt deſigns of Jehoiakim would be fruſtrated. He ſpeaks againſt a prince (probably the king of Tyre) who built with blood and iniquity; and he accuſes another king (perhaps the king of Egypt) of having intoxicated his friend, in order to diſcover his nakedneſs. The third chapter is a ſong or prayer to God, whoſe majeſty he deſcribes with the utmoſt grandeur and ſublimity of expreſſion.

HABDALA, a ceremony of the Jews, obſerved on the ſabbath in the evening, when every one of the family is come home. At that time, they light a taper, or lamp, with two wicks at leaſt: the maſter of the family then takes a cup with ſome wine, mixed with fragrant ſpices; and after having repeated a paſſage or two of Scripture, as for example, "I will take the cup of ſalvation, &c." Pſal. cxvi. and, "The Jews had light and gladneſs, &c." Eſth. viii. he bleſſes the wine and ſpices. Afterwards he bleſſes the light of the fire, and then caſts his eyes on his hands and nails, as remembering that he is going to work. The whole is intended to ſignify that the ſabbath is over, and is from that moment divided from the day of labour which follows. For this reaſon the ceremony is called habdala, which ſignifies diſtinction.

HABEAS CORPORA, in law, a writ iſſued for bringing in a jury, or ſuch of them as refuſe to appear upon the venire facias, for the trial of a cauſe brought to iſſue.

It commands the ſheriff to have the jurors before the judges on ſuch a day, &c. and is of the ſame nature in the Common pleas, as the diſtringas juratores in the court of King's bench.

HABEAS CORPUS, in law, is a writ of two kinds, the one being the great writ of the Engliſh liberty, which lies where a perſon is indicted for any crime or treſpaſs before juſtices of the peace, or in a court of any franchiſe, and on being impriſoned, has offered ſufficient bail, which has been refuſed, though the caſe be bailable; in which caſe he may have this writ out of the King's bench, in order to remove himſelf thither, to anſwer the cauſe at the bar of that court.

The

The practice in this caſe, is firſt to procure a certiorari out of the court of chancery, directed to all the juſtices, for removing the indictment into the King's bench; and upon that to obtain this writ, directed to the ſheriff, for cauſing the body of the party to be brought at a certain day.

The other kind of habeas corpus is uſed for bringing the body of a perſon into court, who is committed to any goal or priſon, either in criminal or civil cauſes; which writ will remove the perſon and cauſe from one court and priſon to another.

No habeas corpus, or other writ, to remove a cauſe from out of an inferior court, can be allowed, if the ſame be not delivered to the judge of the court, before the jury who are to try the cauſe have appeared, and before any of them are ſworn, 43 Eliz. c. 5.

The habeas corpus act, 31 Car. II. c. 2. has ordained, that a perſon may have a habeas corpus from any judge, on complaint made and view of the warrant of commitment, (except ſuch perſon is committed for treaſon or felony expreſſed in the warrant, or ſome other offence that is not bailable) which habeas corpus muſt be made returnable immediately; and on producing a certificate of the cauſe of commitment, the priſoner is to be diſcharged on bail given to appear in the court of King's bench the next term, or next aſſizes, &c. Perſons committed for either treaſon or felony, expreſsly mentioned in the warrant, upon a motion made in open court, in the firſt week of the term, or day of ſeſſions, &c. after commitment, are to be brought to trial; and if they are not indicted the next term or ſeſſions after commitment, on a motion made the laſt day of that term, they ſhall be let out upon bail, except it appear on oath that the king's witneſſes are not ready; and in caſe they are not indicted or tried the ſecond term after commitment, they ſhall be diſcharged.

Judges denying a habeas corpus, ſhall forfeit 500 l. and if an officer refuſe to obey it, or to deliver a true copy of the commitment-warrant, he forfeits 100 l. for the firſt offence.

HABEAS CORPUS AD PROSEQUENDUM, a writ for the removal of a perſon in order to proſecution and trial in the proper county.

HABEAS CORPUS AD FACIENDUM ET RECIPIENDUM, a writ iſſued out of the court of Common-pleas, on behalf of defendants ſued in inferior courts, to remove their cauſe into the ſaid court.

HABEAS CORPUS AD RESPONDENDUM, a writ that lies where a perſon is impriſoned at another's ſuit in any priſon except that of the King's bench, and a third perſon would ſue the priſoner there; in which caſe this writ will remove ſuch perſon from the priſon where he is, into the King's bench, to anſwer the action in that court.

HABEAS CORPUS AD SATISFACIENDUM, a writ that lies againſt a perſon in the Fleet-priſon, &c. to charge him in execution. The delivery of this writ to the warden is ſufficient.

HABENDUM, in law, a term ſignifying to have and to hold.

A deed or conveyance has two principal parts; the premiſes and the habendum. The office of the firſt is, to expreſs the names of the grantor, the grantee, and the things granted: that of the habendum, to ſhew what eſtate or intereſt the grantee is to have in what is granted. According to lord Coke, the habendum is to limit the eſtate, ſo that the general implication, which by conſtruction of law paſſes in the premiſes, is by the habendum controlled and qualified. Thus in a leaſe to two perſons, to have and to hold to the one for life, alters the implication of the joint-tenancy in the freehold, which would paſs by the premiſes, were it not for the habendum.

HABERDASHER, in commerce, a ſeller of hats, or of ſmall wares.

HABERE FACIAS POSSESSIONEM, a writ that lies where one has recovered a term for years in an action of ejectment, in order to put him into poſſeſſion again.

HABERE FACIAS SEISINAM, a writ that lies where a perſon has recovered land in the king's court; directed to the ſheriff, commanding him to give ſeiſin of the land recovered.

HABERE FACIAS VISUM, is a writ that lies in divers caſes, as in dower, formedon, &c. where it is neceſſary to take a view of the lands or tenements in queſtion.

HABERGION, a ſmall coat of mail, or only ſleeves and gorget of mail, formed of little iron rings, or maſhes linked into each other. See GORGET.

HABILIMENTS *of War*, in our ancient ſtatutes, ſignify armour, harneſs, utenſils, or other proviſions for war, without which there is ſuppoſed no ability to maintain war.

HABIT, in philoſophy, an aptitude or diſpoſition either of mind or body, acquired by a frequent repetition of the ſame act.

This habit is by ſome of the ſchoolmen termed *habitus qualitativus*, a qualitative habit, and defined a quality adventitious to a thing, fitting and diſpoſing it either to act or ſuffer. Others again define habit an affection of the mind or body, perſiſting by long uſe and continuance. Hence habits may be diſtinguiſhed into thoſe of the mind and of the body: thus virtue is called an habit of the mind; ſtrength, an habit of the body. All natural habits, whether of body or mind, are no other than the body and mind themſelves conſidered as either acting or ſuffering; or they are modes of the body or mind wherein either perſeveres, till effaced by ſome contrary mode.

Cuſtom, ſays Mr. Locke, ſettles habits of thinking in the underſtanding, as well as of determining in the will, and of motions in the body, all which ſeem to be but trains of motion in the animal ſpirit, which once ſet a-going, continue on in the ſame ſteps they have been uſed to, which by often treading are worn into a ſmooth path, and the motion in it becomes eaſy as well as natural. See ASSOCIATION.

The archbiſhop of Cambray defines habits in general to be the certain impreſſions left in the mind, by means of which we find a greater eaſe, readineſs, and inclination to do any thing formerly done, by having the idea ready at hand to direct us how it was done before.

Thus, for example, we form the habit of ſobriety, by having always before us the inconveniencies of exceſs; the reflections of which being often repeated, render the exerciſe of that virtue continually more and more eaſy.

HABIT, in medicine, denotes the ſettled conſtitution of the body, or the habitude of any thing elſe, as the ſtructure or compoſition of a body, or the parts thereof.

HABIT is alſo uſed for a dreſs or garb, or the compoſition of garments, wherewith a perſon is covered; in which ſenſe we ſay, the habit of an eccleſiaſtic, of a religious, &c. a military habit, &c.

HABITUDE, among ſchoolmen, the reſpect or relation one thing bears to another. See the article RELATION.

HABITUDE is alſo uſed by philoſophers for what we commonly call habit, or a certain diſpoſition or habitude for the performing or ſuffering certain things, acquired by repeated acts of the ſame kind.

HADDOCK, the Engliſh name of a well known fiſh of the gadus-kind, with a bearded mouth, and three fins on the back: its body is whitiſh, the upper-jaw longeſt, and the tail a little forked.

HADE, among miners, ſignifies the ſteep deſcent of a ſhaft, or the like paſſage.

HÆMANTHUS, guinea-orchis, in botany, a genus of plants, the corolla of which conſiſts of a ſingle petal, erect, and divided into ſix erect linear ſegments; the tube is very ſhort, and angular: the fruit is a roundiſh berry, containing three cells; the ſeeds are ſingle and triquetrous; the involucrum has ſometimes ſix leaves.

The flowers ſtand at the top in a kind of little umbel, and are of a very beautifully ſtellated appearance.

HÆMATITES, in natural hiſtory, the blood-ſtone, a kind of mineral ſo called, on account of its reſembling curdled blood, or from its quality of ſtopping blood.

The word is Greek, αἱματίτης, and is derived from αἷμα, blood.

We are to diſtinguiſh carefully between two very different ſpecies of foſſils, called by the common Engliſh name blood-ſtone; the one is a ſemi-pellucid gem, of a green colour, ſpotted with red, and is properly called the heliotrope; the other is a mere ore of iron, and a very rich

rich one. The laſt of theſe is the ſubſtance to be deſcribed in this place.

It is a very ponderous foſſil, ſometimes of a paler, ſometimes of a deeper red, and not unfrequently bluiſh; it is ſometimes found in large irregular maſſes, but more frequently in flat pieces, with botryoide ſurfaces, or in the fragments of ſuch, which, as theſe maſſes naturally break at the jointings of the protuberances that form the ſurface, are uſually rounded at the end, and of a ſomewhat conic or pyramidal figure. Theſe maſſes are of a naturally ſmooth and gloſſy ſurface, and when broken, are found to be compoſed of a number of cruſts laid evenly under one another, and of a regularly ſtriated texture; as theſe cruſts are gradually ſmaller and ſmaller within the maſs, and the ſtriæ all converge toward a center at the baſe of each of them, it is not wonderful that they ſhould naturally ſeparate on breaking into pieces of a pyramidal or conic figure.

This kind of iron ore is very various in its degree of purity and hardneſs, as well as in its figure. The fineſt maſſes of all are thoſe whoſe ſurface terminates in bubbles or round protuberances; the coarſeſt pieces have nothing of this ſtructure, but are compoſed of large ſtriæ, and eaſily ſplit longitudinally according to them: theſe pieces are what the ancients called by a diſtinct name ſchiſtus. There is alſo yet a more impure kind, which is ſcarcely at all either botryoide on the ſurface, or ſtriated, but yet is truly of the ſame kind with the reſt, and is not inferior to them in virtue. The hæmatites of all theſe three kinds is found in England, and in great abundance alſo in the German mines, where maſſes of it are ſometimes met with quite black and of an elegant poliſh; and others covered with golden armature, as high and elegant as if of abſolute leaf gold, laid on in the common way of gilding. Blood-ſtone is to be choſen for medicinal uſe the higheſt coloured and moſt like cinnabar that can be had, and ſuch as is heavieſt and formed with the fineſt ſtriæ. It is accounted aſtringent and deſiccative. It is given in powder, from ten grains to twenty-five for a doſe in hæmorrhages, and is uſed in diſtemperatures of the eyes.

HÆMOPTOSIS, in medicine, a ſpitting of blood, occaſioned by the rupture or eroſion of ſome veſſel in the lungs, commonly attended with a cough and preſſure on the thorax.

The word is Greek, αιμοπτυσις, and is derived from αιμα, blood, and πτυω, to ſpit.

HÆMORRHAGE, *Hæmorrhagia*, in medicine, an eruption of the blood from any part of the body.

The word is Greek, αιμορραγια, and derived from αιμα, blood, and ρηγνυμι, to burſt.

The ſpontaneous evacuations of blood, produced naturally, are made from ſuch parts of the body as are of a lax and tender texture, have very minute and ſlender veſſels every where diſperſed, and not braced up throughout by firm membranes; ſuch as the interior part of the noſtrils, the bronchia, the gums, ſtomach, the ilium, the extremity of the rectum, the uterus and vagina.

The diſpoſition of hæmorrhages is for the moſt part hereditary, and conveyed from parents to their children; but it is moſt ſpeedily put in action, and exerts itſelf, by means of ſuch external cauſes, as render the circulation of the blood too briſk, or increaſe the inteſtine commotion of its parts. The moſt conſiderable of the cauſes are, all exerciſes of the body and mind more intenſe than uſual; aliments or medicines, taken internally, which are either too hot, acrid, or ſpirituous; as alſo the prepoſterous and unſeaſonable uſe of baths, ſudorifics, and purgatives.

As eruptions of blood, when ariſing from a repletion of the veſſels, and redundance of blood, are highly ſalutary, and beneficial to the conſtitution; ſo they are full of danger, when excited by a malignant acrid matter, as in malignant and exanthematous fevers: and when they riſe from an obſtruction, induration, or corruption of the viſcera, eſpecially of the liver, ſpleen, or lungs, they generally prove mortal, becauſe they readily terminate in a cachexy, a dropſy, the morbus niger of Hippocrates, or an hectic which proves fatal.

Since preternatural eruptions of blood generally draw their origins from ſpaſmodic conſtrictions of the veins, we hence plainly underſtand, why hypochondriac patients, in whom the ſtomach and whole nervous canal of the inteſtines are continually afflicted with flatulent diſtentions, and ſpaſmodic ſtrictures, by reaſon of the irregularity of the periſtaltic motion, are ſo highly ſubject to the hæmorrhoids; and why, if the blood is not diſcharged in that manner, their ſymptoms are greatly exaſperated.

With reſpect to the cure of hæmorrhages in general, I would have it obſerved, that their practice is highly prepoſterous, who, maintaining that a redundance of red blood, ſo called by way of eminence, is univerſally the material, as well as accidental cauſe of theſe diſorders, uſe frequent veneſections for their cure; though at the ſame time, at the beginning of the diſorder, for the ſake of prevention, eſpecially in ſanguineous habits, ſeaſonable veneſection is highly ſalutary and beneficial. But the juſteſt and moſt rational intentions of cure conſiſt in driving the impetus of the blood from the part affected by proper remedies; ſuch as bathing the feet, clyſters, frictions, and ligatures of the external parts, warm covering, fomentations, and baths. Then the ſpaſmodic ſtrictures of the nervous parts are to be relaxed. And laſtly, by gentle laxatives, as caſſia, &c. moderate diaphoretics, and abſtinence from light feeding, which generates blood, the redundance of the ſerous colluvies is to be removed, and its accumulation for the future prevented. *Frederic Hoffman.*

HÆMORRHAGE, or *Bleeding at the Noſe*, is owing to the more plentiful appulſe of blood to the noſtrils, by a ſtronger motion of the heart, whereby the ſmall arteries in the pituitary coat become turgid, and too much diſtended, till at length they gape, and the blood guſhes out. A bleeding at the noſe may be promoted when perſons of ſedentary lives, that indulge their appetites, and ſo become plethoric, put their blood into extraordinary agitation, by any of the cauſes already mentioned, or by volatile medicines, hot baths, or ſuddenly chilling their feet, &c. This hæmorrhage differs much as to the quantity: ſome loſe only a few drops, ſome ſeveral ounces, and ſome five or ſix pounds. No hæmorrhage is more apt to return; which it does to ſome in a few days, to others in a few hours. To the plethoric it is generally ſalutary; and there are many inſtances of a vertigo, ſcotomia, dull heavy pains of the head, a phrenzy, and even an epilepſy, being carried off by it. On the contrary, from its ſuppreſſion there have ariſen vertigoes, apoplexies, epilepſies, convulſions, noiſe in the ears, hardneſs of hearing, and even a gutta ſerena.

But enormous and long continued bleedings at the noſe, when they ariſe from ſpaſms of the internal parts, and are preceded with coldneſs of the extreme parts, and fainting fits, generally occaſion death: it is alſo dangerous in ſpotted and malignant fevers, and in chronical diſeaſes. If the bleeding is very inordinate, it will be proper to uſe cooling emulſions, gentle or ſtronger opiates, to moderate the ſpaſtic ſtrictures, as occaſion ſhall require. Camphor mixed with nitre and calx of antimony, will be highly neceſſary, if the matter of exanthemata or cutaneous eruptions is the cauſe of the hæmorrhage, as is often the caſe. A revulſion may be made from the head by bleeding in the lower parts; then by temperate pediluvia, and putting the hands into warm water. After a revulſion by bleeding, there is nothing equal to nitre, to appeaſe the orgaſm of the blood; next to theſe are vegetable acids, ſuch are the juice of Seville oranges, barberries, the water and juice of wood ſorrel; but more eſpecially the diluted ſpirit of vitriol, tincture of roſes, &c.

Externally refrigerants may be mixed with diſcutients, and applied to the forehead, noſe, and neck. In perſons of a bilious conſtitution, cold water alone drank freely, has a good effect.

HÆMORRHOIDAL. The veins and arteries of the rectum and fundament are ſo denominated, as being the ſeat of the hæmorrhoids.

HÆMORRHOIDS, *Hæmorrhoides*, the piles, or a diſcharge of blood from the hæmorrhoidal veins about the anus and rectum.

The word is Greek, αιμορροις, ſignifying the ſame thing, and derived from αιμα, blood, and ρεω, to flow.

Every liberal diſcharge of blood from the veins of the anus

anus is not to be accounted exceſſive and preternatural; but in order to form an eſtimate of this circumſtance, we are carefully to conſider the veſſels, the habit of body, the ſtrength, the age, and the conſtitution of the patient; for it frequently happens that the diſcharge of a certain quantity of blood proves ſalutary and beneficial to ſome; whereas the evacuation of an equal quantity proves hurtful and injurious to others; nor is every hæmorrhoidal diſcharge, though larger than uſual, and excited by the increaſed quantity and commotion of the blood, to be eſteemed a diſeaſe; but only ſuch a diſcharge as continues long, impairs the ſtrength, deſtroys the appetite, the due digeſtion of the aliments, nutrition, and the other functions of the body; and conſequently lays a foundation for violent chronical diſorders.

Every evacuation of blood from the inteſtinum rectum is ſupplied from the hæmorrhoidal veſſels; but the external hæmorrhoidal veſſels rarely flow profuſely, but readily degenerate into painful varices, which, when opened, diſcharge blood, though ſeldom in large quantities. But the internal hæmorrhoidal veſſels, which are ramifications of the ſplenic branch, and are diſtributed to the interior ſubſtance of the inteſtinum rectum, and the ſphincter ani, together with the ſmall arteries ariſing from the inferior meſeraic veſſels, not only diſcharge a large quantity, but, when ſuppreſſed, generate thoſe diſeaſes which ariſe from diſorders of the liver, ſpleen, pancreas, meſentery, and inteſtines.

It is uſually agreed that this ſalutary evacuation from the veins of the anus is owing to a difficult circulation of the blood through the hæmorrhoidal veins, in conſequence of their perpendicular ſituation, and its difficult return to the vena portæ and the liver; and that the diſcharge actually happens, when the extremities of the veſſels, in the inteſtinum rectum, are ſo diſtended by the blood accumulated in them, as at laſt to be ruptured.

The cure.—As this diſorder may proceed from various cauſes, ſo there muſt be various intentions of cure purſued, and different remedies made choice of.

It frequently happens, that when, in plethoric bodies, the hæmorrhoidal diſcharge, uſual at other times, is for ſome time ſtopped, it not only appears again ſuddenly, upon any violent commotion either of body or mind, the liberal uſe of ſpirituous liquors, too hot baths, or upon taking medicines increaſing the inteſtine motion of blood, but continues long, and is attended with a large and ſtrong pulſe. When this is the caſe, the firſt ſtep to be taken is to divert the impetus of the blood; for this purpoſe veneſection in the arm, or an immerſion of the arms in a tepid mixture of water and wine, are of ſingular ſervice: then we are to uſe ſuch things as check the exceſſive inteſtine motion of the ſulphureous parts of the blood, eſpecially things of a diluting and refrigerating nature, ſuch as drinking cold water, eſpecially of the chalybeate kind, tincture of roſes prepared with ſpirit of vitriol, a decoction of hartſhorn, mixed with citron or lemon juice. When, together with a loſs of ſtrength, and an injured ſtate of the nobler functions, a large hæmorrhoidal diſcharge continues for a long time, and the viſcera begin to be tainted, whilſt, at the ſame time, the blood is rather aqueous and ſerous than fibrous, and of a due conſiſtence; thoſe medicines are highly beneficial, which gradually and mildly carry off, by ſtool, the peccant bilious juices, and at the ſame time invite the humours from the inteſtinum rectum to the coats and glands of the other inteſtines. The moſt efficacious of theſe are preparations of rhubarb, with currants and tamarinds; or, if the body is bilious, with cream of tartar, exhibited in a potion rendered agreeable by an eleoſaccharum, prepared with the oil of citron.

In that more obſtinate and difficultly cured ſpecies of the diſorder, which ariſes from an obſtruction, an infarction, or increaſed bulk, of any of the viſcera; ſuch as the liver, ſpleen, and, in women, the uterus;—if there is ſtill any place for the means of relief, ſuch medicines are to be choſen as reſolve the obſtructions without throwing the humours into too violent a commotion.

Among the principal cauſes of a too copious hæmorrhoidal diſcharge, we may juſtly reckon a want of due tone in the inteſtinum rectum, together with its component membranes and veſſels: for this reaſon ſuch medicines are alſo to be uſed as reſtore the ſtrength of parts too much weakened and relaxed; as the extracts of caſcarilla and red ſaunders.

In order to obtain the deſigned effect, external applications of an aſtringent nature are alſo to be uſed; ſuch as the decoction of balauſtine flowers, red-roſes, myrrh, and the Peruvian bark.

In the cure of violent hæmorrhoidal diſcharges, veneſection is to be premiſed, and the primæ viæ cleanſed, either with recent caſſia, or the beſt rhubarb, exhibited in a decoction: then both internal and external medicines, of a corroborative and gently aſtringent nature, may be ſafely uſed.

When a ſudden ſtoppage of the hæmorrhoidal diſcharge is ſucceeded by an uneaſineſs of the præcordia, inflations, reſtleſſneſs, and difficulty of breathing, it is to be recalled by mild laxatives, emollient clyſters, and ſuppoſitories.

In no diſeaſe is an accurate and cautious regimen more neceſſary than in this, ſince, in conſequence of a neglect in this particular, the moſt efficacious remedies will not produce their deſired effect.

When the diſorder is once removed, due pains are to be taken, in order to prevent its return. This intention is moſt commodiouſly and effectually anſwered by veneſection three or four times inſtituted every year; by cleanſing the primæ viæ once a month; and by the prudent uſe of mineral waters, or only of chalybeated milk; and laſtly, all ſuch aliments and laxatives as excite pain, are carefully to be abſtained from.

HAGAI, a canonical book of the Old Teſtament, ſo called from the prophet of that name, who, in all probability, was born at Babylon, from whence he returned with Zerubbabel.

This prophet, by the command of God, exhorted the Jews, after their return from the captivity, to finiſh the rebuilding of the temple, which they had intermitted for fourteen years. His remonſtrances had the deſired effect; and to encourage them to proceed in the work, he aſſured them from God, that the glory of this latter houſe ſhould be greater than the glory of the former: which was accordingly fulfilled, when Chriſt honoured it with his preſence; for, with reſpect to the building, this latter temple was nothing in compariſon of the former.

HAGGARD FALCON, the greeniſh legged falcon, with a livid back. It is a large ſpecies, equal to a full grown hen in ſize. See the article FALCON.

HAGIOGRAPHA, or holy writings, a name given to a particular diviſion of the Old Teſtament, as containing hymns to God, and moral precepts for the conduct of life. The books diſtinguiſhed by this term were the Pſalms, Proverbs, Eccleſiaſtes, and the Song of Solomon.

HAGIOSIDERON, in the Greek church, a name given to an inſtrument made of iron, uſed by the Greeks, under the dominion of the Turks, to ſupply the place of bells, the uſe of which is prohibited. It is a plate of iron about three inches broad, and ſixteen long, faſtened by the middle to a chain or cord, and hung at the church door; on this they ſtrike with an iron-hammer, with a kind of meaſure or cadence that is not diſagreeable.

HAIL, *Grando*, in phyſiology, a watery concretion in the form of pellucid white globules, that fall from the air.

It is thought to be drops of rain frozen in their paſſage through the middle region: or according to the Carteſians, the fragments of a frozen cloud, half melted, precipitated and congealed again.

Hail is of various figures, according to the degrees of heat or cold of the air through which the liquified clouds paſs. It frequently attends thunder and lightning; the nitre that contributes to the one, having alſo a large ſhare in the production of the other.

HAIR, *Crinis* or *Capillus*, a ſort of tegument for the greateſt part of animals. It is found on all parts of the human body, except the ſoles of the feet and palms of the hand.

Hair properly lives and receives nutriment to diſtend it like the other parts of the body; however, this growth

is of a different kind from that of the reſt of the body, and is not immediately derived therefrom, nor reciprocated therewith. It grows like plants out of the earth, or as ſome plants ſhoot from the parts of others; from which, though they draw the nutriment, each has its diſtinct life and œconomy.

Hairs are obſerved by the microſcope to be hollow and furniſhed with a multitude of veſſels; and, however they appear ſmooth to the naked eye, the microſcope ſhews them knotted like ſome ſorts of graſs, and to ſend out branches from their joints.

The branching of the hair is pretty viſible at the extremities by the help of a microſcope; for it is very apt to ſplit, eſpecially if worn too long, or kept too dry; and by the ſame means it appears like a bruſh.

Each hair has a little bulbous or oval root in the ſkin, which is ſometimes plucked away with it. The hair is commonly reputed an excrement, and whatever the nature of its nouriſhment be, it ſeems to be more ſimple than the other humours of the body. For long after death, when all the other parts and humours are corrupted, the hair will vegetate.

The ſize of hair depends on the magnitude of the pores they iſſue from: if thoſe be ſmall, theſe are fine; if the pores are ſtraight, the hairs are ſo too; if thoſe be oblique or ſinous, the hair is curled. Their length depends on the quantity of the proper humour to feed them; and their colour on the quality of that humour: whence at different periods of life the colour uſually differs.

Hair, ſince perukes have been in uſe, makes a conſiderable article in commerce. That of the growth of the northern countries is much perferred to that of the more ſouthern ones.

The merit of good hair conſiſts in its being well fed, and neither too coarſe nor too ſlender; the bigneſs rendering it leſs ſuſceptible of an artificial curl, and diſpoſing it rather to frizzle; and the ſmallneſs making its curl of too ſhort duration. It ſhould be about twenty-five inches long; and as it falls ſhort of this, it decreaſes in value.

Hair is ſold from five ſhillings to five pounds an ounce, according to its quality. The grey is the moſt valuable, next to that the white, &c.

The ſcarcity of grey and white hair put the dealers in that commodity upon artificial methods of rendering hair of theſe colours. They ſpread the hair to bleach on the graſs, after waſhing it firſt in a lixivious water: they alſo dye hair with bizmuth; both which artifices are detected by boiling and drying it.

HAIR'S-BREADTH, a meaſure of length, being the forty-eighth part of an inch.

HAKE, in ichthyology, the Engliſh name of the gadus, with two fins on the back, and the under jaw longeſt. It grows to two feet or more in length, but is the ſlendereſt of all the gadi.

HALBARD, or HALBERT, in the art of war, a well known weapon, carried by the ſerjeants of foot and dragoons.

It is a ſort of ſpear, the ſhaft of which is about five feet long, and made of aſh, or other wood. Its head is armed with a ſteel point, edged on both ſides, not unlike the point of a two-edged ſword. But beſides this ſharp point, which is in a line with the ſhaft, there is a croſs piece of ſteel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent ſharp point at the other; ſo that it ſerves equally to cut down, or puſh withal. It is alſo uſeful in determining the ground betwixt the ranks, and in adjuſting the files of a battalion.

HALBERT, among farriers, is a ſmall piece of iron an inch broad, and three or four inches long, ſoldered to the toe of a horſe's ſhoe, to hinder a lame horſe from treading on his toe.

Theſe halbert-ſhoes neceſſarily conſtrain a lame horſe, when he goes at a moderate pace, to tread or reſt on his heel, which lengthens and draws out the back ſinew, that was before in ſome meaſure ſhrunk.

HALCYON, in ornithology, a name given by the ancients to the iſpida, or king-fiſher. See the article KING-FISHER.

HALCYON DAYS, *Dies halcyonii*, in antiquity, a name given to ſeven days before and as many after the winter ſolſtice; by reaſon the halcyon, invited by the calmneſs of the weather, laid its eggs in neſts built on the rocks, cloſe by the brink of the ſea, at this ſeaſon.

HALF-BLOOD, in law, is where a man marries a ſecond wife, the firſt being dead, and by the firſt venter has a ſon, and by his ſecond venter has likewiſe a ſon, the two brothers in this caſe are but of half blood; they being iſſue by different venters; and on that account, lands in fee cannot deſcend from one to the other; except in caſe of crown-lands, dignities, or eſtates tail. But half blood is no impediment to an adminiſtration, which may be granted to that as well as to the whole blood, of the effects of an inteſtate; and the half-blood ſhall come in for a ſhare of his perſonal eſtate, equally with the whole blood, as the brothers by different venters are next of kin in equal degree. 22 Car. II. c. 10.

HALF-MOON, *Demi-Lune*, in fortification, a work which is commonly made before the curtain or flanked angle of the baſtion: the former generally conſiſts of two little flanks and two faces, which terminate in a ſaliant angle towards the fields; the gorge of the demi lune is terminated by two lines continued from the counterſcarpe of the foſſé, that form an entering angle towards the place, about the middle of the curtain. The demi-lune on the flanked angle of the baſtion differs only from the former, in that it is formed by a circular line; and hence it takes its name demi-lune.

The moderns make uſe of good counterguards to cover the baſtions inſtead of the demi-lunes.

They call a demi-lune what was formerly denominated a ravelin, only that this laſt work has no flanks, and has two faces terminating in a ſaliant angle towards the field.

A demi-lune is ſaid to be crowned when it is covered by a crowned work: it is in like manner ſaid to be a tenaille, when on the right and left it has two works conſtructed in a right angle on the flanked angle of the demi-lune, by the prolongation of its two faces, between twenty-eight and thirty fathoms; each of theſe works having two faces terminating in a ſaliant angle towards the field, and a ditch of nine fathoms that ſeparates them from the demi-lune and counterſcarpe

Laſtly, a demi-lune is called a horned-work, when it is counter-guarded by two works that advance in form of a horn towards the country, having before it a little demi-lune, or lunette, that covers the intermediate ſpace betwixt them, and conſequently the flanked angle of the demi-lune.

HALF-SEAL, that uſed in the the court of chancery for ſealing commiſſions to delegates, upon any appeal, in eccleſiaſtical or marine cauſes.

HALF-TANGENTS. See the articles TANGENT and SCALE.

HALIARDS, in the marine language, the ropes or tackles by which the ſails are hoiſted up along the maſts or ſtays of the ſhip.

HALL, in architecture, a large room at the entrance of a fine houſe and palace. Vitruvius mentions three kinds of halls; the Tetraſtyle, with four columns, ſupporting the platfond, or ceiling; the Corinthian, with columns all round let into the wall, and vaulted over; and the Egyptian, which had a periſtyle of inſolated Corinthian columns, bearing a ſecond order with a ceiling.

The hall is properly the fineſt as well as firſt member of an apartment; and in the houſes of miniſters of ſtate, magiſtrates, &c. is the place where they diſpatch buſineſs, and give audience. In very magnificent buildings, where the hall is larger and loftier than ordinary, and placed in the middle of the houſe, it is called a ſaloon. See APARTMENT.

HALL, in old writers, is alſo uſed for a manſion-houſe; and to this day, in many parts of the kingdom, gentlemen's ſeats are called halls.

HALLAGE, a fee or toll paid for cloth brought to be ſold in Blackwell hall, London.

HALLELUJA, a word ſignifying, praiſe the Lord.

The ſinging halleluja was a ſort of invitatory, or call to each other, to praiſe the Lord.

St. Auſtin ſays, that in ſome churches, it was ſung only

only on Eaſter-day, and the fifty days of Pentecoſt; but that even in thoſe churches where it was moſt in uſe, it was never uſed in the time of Lent. The fourth council of Toledo forbids the ſinging it not only during Lent, but on all other days of faſting; and by the ſame council it is appointed to be ſung after the reading of the goſpel. It was alſo ſung at funerals, as St. Jerom informs us in his epitaph of Fabiola, where he ſpeaks of the whole multitude ſinging pſalms together, and making the golden roof of the church ſhake with echoing hallelujas.

HALO, in phyſiology, a meteor, in form of a luminous ring, or circle, of various colours, appearing round the bodies of the ſun, moon, or ſtars.

The word is formed of the Greek αλως, or αλων, area.

That around the moon is the moſt uſual, and is called *corona*, crown.

Naturaliſts conceive the halo to ariſe from a refraction of the rays of light in their paſſing through the fine rare veſiculæ of a thin nubecula, or vapour, towards the top of our atmoſphere; which account they confirm hence, that a quantity of water being thrown up againſt the ſun, as it breaks and diſperſes into drops, it forms a kind of halo, or iris, exhibiting the colours of the natural rainbow.

M. Huygens ſuppoſes halos, or circles round the ſun, to be formed by ſmall round grains of a kind of hail, made up of two different parts, one of which is opake, and incloſed in the other, which is tranſparent; which is the general ſtructure obſerved in hail.

After the ſame manner he accounts for the parhelia; only that he imagines the icy grains of an oblong figure, and rounding at the ends, like cylinders with round convex tops. Where ſome of theſe cylinders are in an erect poſition, the circle they form will be white, by reaſon of the reflexion of the rays of the ſun on the ſurface of theſe cylinders. He proceeds to account for the coloured halo's and parhelia, from the ſame hypotheſis; and produces an experiment of a glaſs cylinder, a foot long, having within an opake kernel (which was a cylinder of wood), and the ambient ſpace filled with water: this cylinder, being expoſed to the ſun, and the eye diſpoſed in a proper place, the ſeveral ſucceſſive reflexions and refractions neceſſary to produce ſuch an effect did plainly appear.

The light which comes through drops of rain by two refractions, without any reflexion, Sir Iſaac Newton obſerves, ought to appear ſtrongeſt, at the diſtance of about twenty-ſix degrees from the ſun, and to decay gradually both ways, as the diſtance from him increaſes and decreaſes: and the ſame is to be underſtood of light, tranſmitted through ſpherical hailſtones.—Add, that if the hail be a little flatted, as is often the caſe, the light tranſmitted may grow ſo ſtrong at a little leſs diſtance than that of twenty-ſix degrees, as to form a halo about the ſun or moon; which halo, as often as the hailſtones are duly figured, may be coloured; and then it muſt be made red within by the leaſt refrangible rays, and blue without by the moſt refrangible ones; eſpecially if the hailſtones have opake globules of ſnow in their center, to intercept the light within the halo, as Huygens has obſerved, and make the inſide thereof more diſtinctly defined than it would otherwiſe be.

Such hailſtones, though ſpherical, by terminating the light by the ſnow, may make a halo red within, and colourleſs without, and darker in the red than without, as uſed to be: for of thoſe rays which paſs cloſe by the ſnow, the rubiform will be leaſt refracted, and ſo will come to the eye in the directeſt lines.

HALTER-CAST, among farriers, an excoriation of the paſtern occaſioned by a horſe's endeavouring to ſcrub the itching part of his body near the head and neck, when one of his hinder feet entangling in the halter, he ſometimes receives very dangerous hurts in the hollow of the paſtern by his ſtruggling to diſengage himſelf.

For the cure of this, take linſeed oil and brandy, of each an equal quantity; ſhake them together in a bottle till they are well mixed, and anoint the place morning and evening, having cut firſt away the hair; but care muſt be taken to keep the foot very clean.

HALTING, among farriers, a limping or going lame, or irregularity in the motion of a horſe, ariſing from a lameneſs in the ſhoulder, leg, or foot, which makes him ſpare the part, or uſe it timorouſly.

HALYMOTE, in old law books, ſignifies a holy or eccleſiaſtical court. See the article COURT.

HAM, in anatomy, the part behind the knee. See KNEE and LEG.

HAM, in old law writers, a Saxon word uſed for a home or dwelling place, for a borough and a village, and alſo for a little narrow ſlip of meadow.

HAM, in cookery, the leg and thigh of a hog ſeaſoned and dried.

HAMADRYADS, *Hamadryades*, fabulous deities revered among the ancient heathens, who were ſuppoſed to preſide over woods and foreſts, and to be incloſed under the bark of oaks, &c. and to live and die with the trees they belong to.

The word is Greek, αμαδρυαδες, and compounded of αμα, together, and δρυς, an oak.

HAMBLING, or HAMELLING, in the foreſt law, is the hamſtringing of dogs, or cutting the great tendon called the hamſtring.

HAMLE, the name of the eleventh month of the Ethiopian year, beginning on the twenty-fifth of June, old ſtyle.

HAMLET, HAMEL, or HAMPSEL, is a ſmall village, or part of a pariſh.

HAMMER, a well known tool uſed by mechanics, conſiſting of an iron head, fixed croſſwiſe upon a handle of wood.

HAMMOCK, among ſailors, a piece of canvas about ſix feet long, and three feet wide, drawn together at the two ends, and hung horizontally under the deck for the ſailors to ſleep in. In time of battle they are ſtrongly faſtened and laid above the rails on the quarter-deck and fore-caſtle, to barricade and prevent the execution of ſmall ſhot.

HAMSOKEN, in old law books, ſignifies the liberty or privilege a man enjoys in his own houſe. It is alſo ſaid to ſignify a franchiſe granted to lords of manors, by which they hold pleas, and take cognizance of the breach of that immunity.

HANAPER, or HANPER, in chancery. See HANPER.

HAND, *Manus*, in anatomy; the laſt part of the upper extremity is divided into the carpus, metacarpus, and fingers, or into the inſide, hollow, or palm, and into the outſide or back of the hand.

The carpus or wriſt, conſiſts of eight ſmall, unequal, and irregular bones; and, taken all together, repreſent a ſort of grotto of an irregular quadrangular figure, and connected principally with the baſis of the radius.

The bones of the carpus are divided into two rows, and each row conſiſts of four bones; and, to diſtinguiſh theſe eight bones from each other, they are called firſt, ſecond, third, and fourth bones of the firſt or ſecond row, beginning to count from the radius or thumb.

The firſt bone of the firſt row Lyſerus calls os ſcaphoides or naviculare, from its reſemblance to a ſmall boat; the ſecond os lunare, becauſe one of its ſides is in form of a creſcent; the third os cuneiforme; the fourth os piſiforme, or biculare, and lenticulare, from its figure and ſize; the firſt of the ſecond row, os trapezium; the ſecond os trapezoides or pyramidale; the third os magnum; and the fourth os unciforme.

The bones of the carpus are articulated with each other by arthrodia, but the firſt row forms a ſort of ginglymus with the ſecond. The inner ſubſtance of all theſe bones is ſpongy, and their ſurfaces are not very compact.

The metacarpus conſiſts of four bones, one ſide of which forms the palm of the hand, the other the back of the hand. Theſe bones are long, thicker at the extremities than at the middle, and of an unequal length and bigneſs. The firſt is the largeſt, the reſt are leſſened by degrees in all their dimenſions. The fingers make the third part of the hand, and terminate the whole upper extremity; they are five in number in each hand, called the thumb, the fore-finger, the middle-finger, the ring-finger, and the little-finger. The thumb is the biggeſt of all the fingers; next to that, the third, called the long-finger; the ſecond and fourth are ſhorter than the third; the

the fourth being a very little longer than the ſecond; the fifth is the ſmalleſt of all.

Each thumb and finger conſiſt of three pieces, called phalanges; the firſt of which is longer and thicker than the ſecond; and the ſecond than the third.

The carpus is the baſis and center of all the motions of the hand, except that of rotation: by means thereof we can bend the hand in all directions, but with more eaſe towards the ſides and edges, than any other way.

The radius is in a manner the handle of the hand; and it is chiefly by means thereof that we can move the hand reciprocally as on the axis, turning either edge of it towards the body. This motion is termed pronation, and when the cubital or ſmall edge is towards the body, it is termed ſupination. In the natural and moſt ordinary ſituation of the hand, the palm is turned towards the body, and not the edges.

The ulna ſupports the handle of the hand, without being itſelf articulated with the hand.

All the bones of the carpus, metacarpus, and fingers, are cruſted over with cartilages.

The ligaments of the carpus are very numerous: ſome of them tie each bone to one or two neighbouring bones in the ſame rank; and theſe are compoſed of a great number of very ſhort filaments; ſome of them tie the bones of one row to thoſe of the other, which are likewiſe made of many filaments, but not ſo ſhort as the former. Laſtly, there are other ligaments of the carpus, by which the three firſt bones of the firſt row are connected to the bones of the fore-arm: and to theſe may be added the ligaments, by which the bones of the ſecond row are joined to thoſe of the metacarpus, and firſt phalanx of the thumb.

There is likewiſe a conſiderable ligament called the inner tranſverſe or annular ligament of the carpus.

The bones of the metacarpus, beſides the ſhort ligaments by which they are tied to the ſecond row of the bones of the carpus, have ſeveral ligaments by which both their baſes and heads are connected together. The baſes of the third and fourth bones are not ſo cloſely tied as the reſt; and therefore they have a very ſenſible motion, which, however, is greater in the fourth than in the third.

The heads of theſe bones are firmly tied to each other by a ſtrong tranſverſe ligament, ſituated in the palm of the hand. The firſt phalanx of the thumb is fixed to the os trapezium by ſhort ligaments, which paſs obliquely over the articulation. The firſt phalanx of the other four fingers are joined to the heads of the metacarpal bones by ligaments like the former, which are ſtrengthened by adhering to the tranſverſe ligament. The ſecond phalanx of the thumb is joined to the firſt by ligaments of the ſame kind.

The third phalanx of the thumb is joined to the ſecond, the ſecond phalanges of the other finger to the firſt, and the third to the ſecond, by lateral ligaments that ſpread from a point fixed in the lateral tubercles of the heads of the phalanges, and are interſected by their other extremity, like radii, in the baſes of the neighbouring phalanges.

The two firſt phalanges of each finger have a very ſtrong ligamentary vagina inſerted in the rough lines or ridges on their flat ſides.

All theſe bones would be uſeleſs, if they were not furniſhed with muſcles, in order to move them in ſuch directions and for ſuch purpoſes as the exigencies of mankind may require. The ancient anatomiſts mention but one muſcle belonging to the palm, which is the palmaris longus: but Fallopius deſcribes the palmaris brevis, communicated to him by Johannes Baptiſta Cunanus, an eminent anatomiſt, his cotemporary, and was firſt publiſhed by Valverda, in his anatomy written in Spaniſh.

The muſcles of the four fingers are divided into common and proper: the common are ſuch as ariſe from the external or internal protuberances of the os humeri, and ſubdividing themſelves, are inſerted into moſt, if not all the fingers; theſe are the perforatus, perforans, lumbricales, and extenſor communis digitorum.

The proper muſcles have their beginnings diſtinct, and are inſerted, without any ſubdiviſion, into each reſpective finger, as the interoſſei, extenſor indicis, abductor indicis, extenſor minimi digiti, and abductor minimi digiti.

Authors diſagree concerning the number, riſe, and inſertion of the muſcles of the thumb, which may partly proceed from that great variety obſervable in divers ſubjects: theſe are the flexor tertii internodii, or longiſſimus pollicis, abductor pollicis, flexor primi et ſecundi oſſis pollicis, abductor pollicis; extenſor primi internodii pollicis, extenſor ſecundi internodii oſſis pollicis, and extenſor tertii internodii oſſis pollicis.

The muſcles of the carpus are generally well deſcribed by moſt authors, and receive their names from their ſituation and uſe, as flexor carpi radialis, flexor carpi ulnaris, extenſor carpi radialis, and extenſor carpi ulnaris. All theſe muſcles are deſcribed under their proper names.

The cubital artery, in its courſe between the heads of the ulna and radius, ſends off two principal branches, the one internal, the other external, called the interoſſeous arteries of the fore-arm; the external interoſſeous artery is diſtributed to the ulnaris externus, extenſor digitorum communis, to the extenſores pollicis, indicis, and minimi digiti, communicating with ſome branches of the internal interoſſeous artery: a little farther it unites with a branch of the internal interoſſeous artery, being diſtributed with it on the convex ſide of the carpus and back of the hand, communicating with the arteria radialis and a branch of the cubitalis.

By theſe communications this artery forms a ſort of irregular arch, whence branches are detached to the external interoſſeous muſcles, and the external lateral parts of the fingers.

The internal interoſſeous artery goes to the convex ſide of the carpus and back of the hand, where it communicates with the external interoſſeous artery, the radialis and internal branches of the cubitalis.

From the origin of the two interoſſeæ, the cubitalis runs down between the perforatus, perforans, and ulnaris internus, along the ulna, ſending branches to the neighbouring parts: afterwards it paſſes over the internal tranſverſe ligament of the carpus, by the ſide of the os piſiforme; and having furniſhed the ſkin, palmaris brevis, and metacarpus, it ſlips under the aponeuroſis palmaris, giving off one branch to the hypothenar minimi digiti, and another which runs towards the thumb. It likewiſe ſends off a branch, which, running between the third and fourth bones of the metacarpus, reaches to the back of the hand, where it communicates with the external interoſſeous artery. Afterwards, having ſupplied the interoſſeous muſcles, it communicates with the radialis, and they both form an arterial arch in the hollow of the hand. This arch from its convex part ſends off three or four branches; the firſt goes to the inner and back part of the little finger; the other three run in the interſtices of the four metacarpal bones, near the heads of which each is divided into two branches, which paſs along the two internal lateral parts of each finger; and at the ends of the fingers theſe digital arteries unite. Sometimes the arch terminates by a particular branch in the middle fingers, and then it communicates with the radial artery. This arch likewiſe ſends from its concave ſide, towards the ſecond phalanx of the thumb, a branch for the lateral internal part thereof, and then ends near the head of the firſt metacarpal bone, by a communication with the radialis, having firſt given a branch to the foreſide of the index, and another to the ſide of the thumb next the former. It likewiſe ſends ſmall twigs to the interoſſeous muſcles, the lumbricales, palmaris, and other neighbouring parts; and, laſtly, to the integuments.

The radial artery, having reached the extremity of the radius, runs nearer the ſkin, eſpecially towards the anterior edge of the bone, being the pulſe we feel there. It gives off a branch there to the thenar; and alſo, communicating with the arch of the cubital artery in the palm, and ſending off ſome cutaneous branches, it detaches one along the internal lateral part of the thumb, and turns toward the hollow of the hand: at this turning it ſends off a branch to the external lateral part of the thumb. It likewiſe ſends branches which run more or leſs tranſverſely, and communicates with an oppoſite branch of the cubitalis, furniſhing the external interoſſeous muſcles and integuments of the back of the hand and convex ſ

of the carpus. Laſtly, the radial artery terminates near the baſis of the firſt metacarpal bone. When the arch of the cubitalis ends at the middle finger, the radialis runs along the inner or concave part of the firſt metacarpal bone, at the head of which it terminates by two branches; one runs along the inner and anterior lateral part of the index, the other paſſes between the flexor tendons of this finger and the metacarpal bone; and, having communicated with the cubital branch of the middle finger, advances on the poſterior lateral part of the index, all the way to the end of that finger, where it unites again with the firſt branch.

The vena cephalica, having reached the extremity of the radius, is diſtributed by numerous areolæ, almoſt in the ſame courſe with the radial artery. A particular branch goes out from it which runs more or leſs ſuperficially between the thumb and metacarpus, by the name of cephalica pollicis. The areolæ furniſh the interoſſeous muſcles and integuments, and communicate with a ſmall branch from the baſilica, called by the ancients ſalvatella; which goes to that ſide of the little finger next the ring-finger. In the other fingers this vein follows nearly the ſame courſe with the artery.

The cubital nerve, at the lower extremity of the ulna, is divided into two branches, one large, the other ſmall: the large branch paſſes under the great tranſverſe ligament of the carpus, to that part of the palm which anſwers to the laſt two fingers, where it gives ſome filaments to the integuments and ligaments of the carpus. Afterwards it divides into three branches, one of which forms a kind of arch, being diſtributed to the neighbouring ſmall muſcles of the thumb and to the interoſſei; the ſecond is bifurcated, and goes to the correſponding lateral concave parts of the ring and little fingers; and the third goes to the oppoſite lateral part of the little finger, and to the neighbouring muſcles.

The ſmall branch goes to that part of the back of the hand, which anſwers to the laſt two fingers: it is diſtributed to the lateral convex parts of theſe two fingers, in the ſame manner as the other branch to the lateral concave parts. It likewiſe ſupplies the muſculus hypothenar, metacarpus, and the integuments, and communicates with a branch of the nervus medianus.

After that, the internal cutaneous nerve dividing into two branches, the one is ramified on the ſkin that covers the wriſt and beginning of the palm; the other, running a little more backward along the integuments which cover the muſculus ulnaris internus and ulna, is ramified all the way to the little finger.

The radial nerve is diſtributed to all the integuments which cover the radius, and to thoſe which cover the exterior parts of the carpus, and back of the hand, all the way to the thumb. Having got to the lower part of the radius, it is diſtributed into three branches to the convex lateral parts of three fingers and a half. One branch goes to the internal lateral part of the thumb and to the integuments. The ſecond is divided into two for the external lateral part of the thumb, and anterior lateral part of the index, giving filaments in its paſſage to the integuments of the metacarpal bones: the third is divided into ſeveral ramifications which go to the poſterior lateral parts of the index, to both ſides of the middle finger, and to the anterior lateral part of the ring-finger. Through all this courſe this branch ſupplies the integuments and interoſſeous muſcles. The trunk or largeſt branch is loſt in the extenſor digitorum communis, and in the muſcles of the carpus and thumb, having firſt communicated with a branch of the muſculo-cutaneous nerve. *Winſlow.*

HAND, in the manege, a meaſure of four inches, or of a clinched fiſt, by which the height of a horſe is computed. Thus a horſe of war ſhould be ſixteen hands high.

Hand is alſo uſed for the diviſion of a horſe into the fore and hind parts. The parts of the fore-hand are the head, neck, and fore-quarters; and thoſe of the hind-hand include all the other parts of his body.

Hand is alſo uſed for the horſeman's hand. Thus ſpear-hand, or ſword-hand, is the horſeman's right hand; and bridle-hand is his left hand.

HAND-BREADTH, a meaſure of three inches.

HAND-HOOK, an inſtrument uſed by ſmiths to twiſt ſquare iron.

HAND-SCREW, an inſtrument more uſually called a jack. See the article JACK.

Harmonical HAND, in muſic, a name given to the ancient diagram. See DIAGRAM.

Impoſition of HANDS, the ceremony of laying the hands on the head of a perſon to be ordained. See ORDINATION.

HANDS, in heraldry, are borne in coat armour dexter and ſiniſter, that is, right and left, expanded or open. Theſe are the moſt neceſſary parts of the human body, as they ſerve to expreſs all ſorts of actions, and even our very thoughts and deſigns; thus joining of hands is an univerſal token of friendſhip, and clapping of hands a general mark of applauſe.

HANDING *the Sails*, in the ſea-language, the ſame as furling, which ſee.

HANDSPIKE, a ſort of bar uſed to heave the windlaſs round at the time of weighing the anchor. It is alſo uſed as a lever on many occaſions. See the article WINDLASS.

HANKS, in the marine, certain wooden rings fixed upon the ſtays of a ſhip, to which the ſtay-ſails are faſtened in different places, as a curtain is faſtened to the rings which run upon its rod: by theſe the ſails are eaſily extended upon the ſtays to their utmoſt ſtretch.

HANPER, HANAPER, or HAMPER, an office of the chancery, anſwering to the fiſcus of the Romans.

HANSE, or HANS, a company of merchants united for the promotion and advantage of trade.

HANSE-TOWNS, port-towns of Germany, of which Lubec and Hamburg were the chief. They were formerly all of them imperial cities, confederated for their mutual defence, and the protection of their trade.

HAPPINESS, among philoſophers, conſiſts in the enjoyment not only of the goods of the body, as health, ſtrength, neatneſs, decency, &c. but alſo of the more refined goods of the mind, as knowledge, memory, taſte, and eſpecially the moral virtues, magnanimity, fortitude, benevolence, &c.

HAQUEBUT, HAGBUT, HARQUEBUSS, or ARQUEBUSE, a kind of fire-arm.

The word is French, *arquebuſe*, and derived from the Italian *arco*, a bow, and *buſio*, a hole; on account of the touch-hole at which the priming is put, and as it ſucceeded to the ancient bow.

HARANGUE, a ſpeech made by an orator in public.

It is frequently uſed for a pompous and prolix declamation.

HARBINGER, an officer of the king's houſhold, having four yeomen under him, who ride a day's journey before the court, when it travels, to provide lodgings, &c.

HARBOUR, a place where ſhips may ride ſafe at anchor, chiefly uſed in ſpeaking of thoſe ſecured by a boom and chain, and furniſhed with a mole. See BOOM, CHAIN, and MOLE.

HARDENING, the act of communicating a greater degree of hardneſs to a body than it had before.

Steel and iron are hardened and tempered divers ways, as by the hammer; quenching it, when hot, in cold water; caſe-hardening, &c.

To harden and temper Engliſh, Flemiſh, and Swediſh ſteel, they heat it pretty high, then ſuddenly quench it in water to make it very hard: Spaniſh and Venice ſteel need only a blood-red heat, and then be quenched. Sometimes they rub ground indigo and ſallad oil upon it with a woollen rag, while it is heating, and let it cool of itſelf.

If the ſteel be too brittle for an edge, ſpring, &c. bring it down thus: take a piece of grind-ſtone or whet ſtone, and rub hard the work on it to take the black ſcurf off, and brighten it; then let it heat in the fire, and it will gradually change colour, coming firſt to a light goldiſh colour, then to a darker goldiſh colour, and at laſt to a blue colour: chooſe which of theſe the work requires, and quench it ſuddenly in water.

Caſe-HARDENING is a leſſer degree of ſteel-making, and performed by baking razors, files, knife-blades, &c.

in a kind of oven, and laying over them a ſtrata of powdered charcoal, hoofs, horns, &c. ſo as to exclude the air; and thus by baking to give a coat of ſteel to theſe inſtruments ſome depth below their ſurface.

Others cover the iron or ſteel all over with a compoſition of an equal quantity of powdered horn, bay-ſalt, and ſtale urine, or white wine vinegar, well mixed together, and then wrap it up in loam or plate iron, and bring the whole to the fire to a blood-red heat, and no higher; and, laſtly, take it out and quench it.

HARDENING *of Timber*. The Venetians are famous for the ſoundneſs of their ſhips, which do not rot as thoſe of other nations, but will endure many times the common period. Tachenius tells us, that the whole ſecret of this conſiſts in the manner of their hardening of their timber intended for this ſervice; and that this is done by ſinking it in the water while green, and leaving it there many years. This prevents the alkali, or that ſalt which furniſhes the alkali in burning, from exhaling afterwards; and by this means the timber becomes almoſt as incorruptible as ſtone. It is evident that the exhaling of this ſalt, and the rotting of wood, have ſome very great connection with one another, ſince, the more ſound any piece of timber is, the more ſalt it proportionably yields; and the wood which is rotten is found on trial to contain no ſalt at all. See the article TIMBER.

HARDNESS, in philoſophy, that quality in bodies, whereby their parts mutually cohere together, ſo as not to give way to an external impulſe, nor yield inwards, without breaking. Hardneſs in this ſenſe is in contradiſtinction to ſoftneſs. See the article ATTRACTION *of Coheſion*.

HARDS, or HURDS, the coarſer part of hemp or flax, ſeparated from the fine. See the articles HEMP and FLAX.

HARDY SHRUBS, among gardeners, are thoſe which endure the auſterity of the winter.

The two hardieſt ſhrubs we are poſſeſſed of, are the ivy and box; theſe ſtand the ſeverity of our ſharpeſt winter unhurt, while other ſhrubs periſh, and trees have their ſolid bodies ſplit and torn to pieces. In the hard winter of the year 1683, theſe two ſhrubs ſuffered no injury any where; though the yews and hollies, which are generally ſuppoſed very hardy, were this winter in ſome places killed, and in others, ſtripped of their leaves, and damaged in their bark. Furze buſhes were found to be ſomewhat harder than theſe, but they ſometimes periſhed, at leaſt down to the root. The broom ſeemed to occupy the next ſtep of hardineſs beyond theſe; this lived where the others died; and where even this died, the juniper ſhrubs were ſometimes found unhurt. This laſt is the only ſhrub that approaches to the hardineſs of the box and ivy, but even this does not quite come up to them; for while they ſuffer nothing in whatever manner they are expoſed, the juniper, though it bears cold well under the ſhelter of other trees, yet cannot bear the viciſſitudes of heat and cold, inſomuch that ſome juniper ſhrubs were found half dead, and half vigorous; that ſide which faced the mid-day ſun, having periſhed by the ſucceſſive thawings and freezings of its ſap; while that which was not expoſed to the viciſſitudes of heat, had bore the cold perfectly well. Such ſhrubs as are not hardy enough to defy the winter, but appear half dead in the ſpring, may often be recovered by Mr. Evelyn's method of beating their branches with a ſlender hazel wand, to ſtrike off the withered leaves and buds, and giving a free paſſage to the air to the internal parts. Where this fails, the method is to cut them down to the quick; and if no part of the trunk appears in a growing condition, they muſt be taken off down to the level of the ground. *Phil. Tranſ.* N°. 165.

HARE, in zoology, an animal of the lepus kind, diſtinguiſhed by its abrupt tail and black eyes. It greatly reſembles the rabbit, but is larger, and ſomewhat longer, in proportion to its thickneſs; and its ears are remarkably long, being always in a poſition to receive the leaſt ſound, and moveable with ſurpriſing eaſe.

HARE-LIP, *Lebium Laporinum*, in ſurgery. See the article LIP.

HARIOT, or HERIOT, in law, a due belonging to a lord at the death of his tenant, conſiſting of the beſt beaſt, either horſe, ox, or cow, which he had at the time of his death; and in ſome manors, the beſt goods, piece of plate, &c. are called hariots.

HARLEQUIN, a buffoon or merry-andrew; but is now uſed for a perſon of extraordinary agility, dreſſed in party-coloured cloaths, the principal character in a pantomime entertainment. See the article PANTOMIME.

HARMONIA, in anatomy, a ſpecies of articulation, being a kind of ſymphyſis intended for abſolute reſt. See ARTICULATION.

HARMONICA, or, as it is often improperly called, ARMONICA, among muſicians, is an inſtrument compoſed of muſical glaſſes.

The following is a very curious inſtrument of this kind, made by the inventor Mr. Thomas Dobb of St. Paul's church-yard; and, being the moſt perfect as well as fineſt toned inſtrument in uſe, may with great propriety be conſidered as an improvement in muſic.

The inſtrument has this peculiar property, that it never varies or goes out of tune; and is ſo conſtructed as to play a thorough baſs: the contrivance is as follows:

A A A A (plate LXXII. *fig.* 1.) the frame with the treddle or lever for the foot to put the machine in motion, faſtened at one end to the croſs-bar of the frame 1, with a leather ſtrap for a joint, and goes the whole length clear through the other end between two ſtraight pillars, 2, 3, made to fit, that it may work freely up and down, at the ſame time keeping it in its proper poſition, ſo as to turn the above wheel round. B B, the caſe to contain the glaſſes, four feet ſix inches long, and fourteen inches ſquare, with an octogon top opening in the middle when played on, and locked up at other times. C, the large wheel, with a leaden weight caſt on it, and turned quite true, and fixed on the ſpindle with the glaſſes, with a peg turned with a nob on the end to keep the ſtring on when faſtened to the treddle, and turned with the foot, which is fixed in the ſide of the wheel, three inches from the center: the uſe of the weight is to regulate the motion, and overcome the friction of the fingers in playing. D, E, F, G, the glaſſes of a ſemi-circular form perfectly tuned, and of different ſizes, as in the plate, ſo as to get the tones proper to make the inſtrument of three octaves, or more, including the ſemi-tones, with a hole through the center to faſten on the arbor or ſpindle H, ſo as to run nearly true when turned to play on the inſtrument, and then laid horizontally between two rollers fixed at each end of the caſe, which makes them turn quite eaſy, and prevents friction.

What remains further to be ſaid of the inſtrument is with regard to the method of performing on it, which is done by friction in the following manner: The glaſſes are rubbed all over with a wet ſpunge dipped in very clean water: care muſt be taken that no greaſe comes to them; for was the glaſs greaſy, it would be impoſſible to get out any tone: the ſame care muſt likewiſe be taken that your hands are clean. Mr. Dobb always, before he begins to play on the inſtrument, rubs all his fingers over with whiting or chalk, and waſhes it clean off, which gives the fingers a roughneſs, that, when preſſed on the glaſſes, brings the tone out immmediately; ſo that you may play any tune, either in full chorus, or only in parts, as is moſt agreeable.

This inſtrument is beſt adapted to ſlow muſic; for in that is moſt diſcovered thoſe exquiſite fine tones peculiar to it; and which, if run over in a hurry, would not be ſo diſtinctly heard; though by a proper execution every thing might doubtleſs be done on this that can be performed on any other inſtrument.

HARMONICAL ARITHMETIC, that part of arithmetic which conſiders muſical intervals, expreſſed by numbers, in order to our finding their mutual relations, compoſitions, and reſolutions.

HARMONICAL COMPOSITIONS, in a general ſenſe includes both harmony and melody, that is, of muſic or ſongs, both in a ſingle part, and in ſeveral parts.

HARMONICAL INTERVAL, in muſic, denotes the difference of two ſounds, which is agreeable to the ear, whether in conſonance or ſucceſſion; and are, therefore, the ſame with concord. See the articles CONCORD and INTERVAL.

HARMONICAL PROPORTION. See the article PROPORTION.

HARMONICAL SERIES, a ſeries of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make an harmonical ſeries: ſuch is 30 : 20 : 15 : 12 : 10. Or, if every four terms immediately next each other are harmonical, it is alſo a continual harmonical ſeries, but of another ſpecies, as 3, 4, 6, 9, 18, 36, &c.

HARMONICAL SOUNDS, an appellation given, by Mr. Sauveur, to ſuch ſounds as always make a determinate number of vibrations, in the time that one of the fundamentals, to which they are referred, makes one vibration.

Harmonical ſounds are produced by the parts of chords, &c. which vibrate a certain number of times, while the whole chord vibrates once.

The relations of ſounds had only been conſidered in the ſeries of numbers, 1 : 2, 2 : 3, 3 : 4, 4 : 5, &c. which produced the intervals called octave, fifth, fourth, third, &c. Mr. Sauveur firſt conſidered them in the natural ſeries, 1, 2, 3, 4, 5, &c. and examined the relations of ſounds ariſing thereſrom. The reſult is, that the firſt interval, 1 : 2, is an octave; the ſecond, 1 : 3, a twelfth; the third, 1 : 4, a fifteenth, or double octave; the fourth, 1 : 5, a ſeventeenth; the fifth, 1 : 6, a nineteenth, &c.

This new conſideration of the relations of ſounds, is more natural than the old one; and is, in effect, all the muſic that nature makes without the aſſiſtance of art. See the articles CHORD, VIBRATION, ORGAN, &c.

HARMONICS, *Harmonica*, a diviſion of the ancient muſic. It conſiders the differences and proportions of ſounds with reſpect to gravity and acuteneſs, in contradiſtinction to rhythmica or metrica.

HARMONY, in muſic, the agreeable reſult of an union of ſeveral muſical ſounds, heard at the ſame time.

The word is Greek, ἁρμονία, from ἁρω, to fit or adapt.

As a continued ſucceſſion of muſical ſounds produces melody, ſo a continued combination of them produces harmony.

Harmony, ſtrictly taken, denotes conſonance, and ſo is equivalent to ſymphony. The ancients ſeem to have been entirely unacquainted with harmony, the ſoul of modern muſic. We have inſtances indeed of their joining ſeveral voices or inſtruments in conſonance; but they were either uniſons or octaves in every note; and ſo all performed the ſame melody, and conſtituted one and the ſame thing.

When the parts differ not in the tenſion of the whole, but in the different relations of the ſucceſſive notes; it is this that conſtitutes the modern harmony.

In every compounded ſound, where there are no more than three ſimple ones, there are three kinds of relation, to wit, the primary relation of every ſimple ſound to the fundamental, or graveſt, whereby they make different degrees of concord with it; the mutual relations of the acute ſounds with each other, whereby they mix either concord or diſcord into the compound; and the ſecondary relation of the whole, whereby all the terms unite their vibrations, or coincide more or leſs frequently.

Suppoſe four ſounds A, B, C, D, of which A is the graveſt, B next, then C, and D the acuteſt. Here A is the fundamental; and the relations of B, C, and D to A are primary relations: ſo if B be a third *g* above A, that primary relation is 4 to 5; and if C be fifth to A, that primary relation is 2 to 3; and if D be octave to A, that is 1 to 2. For the mutual relations of the acute terms B, C, D, they are had by taking their primary relations to the fundamental, and ſubtracting each leſſer from each greater; thus B to C is 5 to 6, a third *l*; B to D is 5 to 8, a ſixth *l*, &c.

Laſtly, to find the ſecondary relation of the whole, ſeek the leaſt common dividend to all the leſſer terms of the primary relations, that is, the leaſt number that will be divided by each of them exactly; this is the thing ſought, and ſhews, that all the ſimple ſounds coincide, after ſo many vibrations of the fundamental as the number expreſſes.

So in the preceding example, the leſſer terms of the three primary relations are 4, 2, 1, whoſe leaſt common dividend is 4; conſequently, at every fourth vibration of the fundamental, the whole will coincide.

The proper ingredients of harmony are concords, and all diſcords, at leaſt in the primary and mutual relations, are abſolutely forbidden. It is true, diſcords are uſed in muſic, only to ſet off the concords by their contraſt.

Hence any number of concords being propoſed to ſtand in primary relation with a common fundamental, we diſcover whether they conſtitute a perfect harmony, by finding their mutual relations. Thus, ſuppoſe the greater third, fifth, and octave given, their mutual relations are all concord, and therefore may ſtand in harmony; for the greater third and fifth are to one another as 5 : 6, a leſſer third; the greater third and octave are as 5 : 8, a leſſer fourth; and the fifth and octave are as 3 : 4, a leſſer fourth. But if 4th, 5th, and octave be propoſed, it is evident they cannot ſtand in harmony; becauſe betwixt the fourth and fifth there is a diſcord, namely, the ratio 8 : 9.

To know if ſounds can ſtand in harmony, find the primary and all the mutual relations which muſt be concord. So 4 : 5 : 6 : 8 may ſtand in harmony, as each to each is concord; but 4, 6, 9 cannot, becauſe 4 : 9 is diſcord.

The perfection of harmonies depends on all the three relations; upon comparing two harmonies, which have an equal number of terms, that which has the beſt primary and ſecondary relations, is moſt perfect. But in caſes where the advantage is in the primary relation of the one, and the ſecondary of the other, there is no certain rule: the primary are certainly the moſt conſiderable; but how the advantage in theſe ought to be proportioned to the diſadvantage in the other, or *vice verſa*, we know not: ſo that a well tuned ear muſt be the laſt reſort.

Harmony is divided into ſimple and compound. Simple is that where there is no concord to the fundamental above an octave. The ingredients of ſimple harmony are the ſeven ſimple original concords, of which there can be but eighteen different combinations that are harmony, as in the following table.

Fifth Oct.	2.	Third *g* 5th	4.	Third *g* 5th	Oct.
Fourth Oct.	3.	Third *l* 5th	10.	Third *l* 5th	Oct.
Sixth *g* Oct.	3.	Fourth 6th *g*	3.	Fourth 6th *g*	Oct.
Third *g* Oct.	4.	Third *g* 6th *g*	12.	Third *g* 6th *g*	Oct.
Third *l* Oct.	5.	Third *l* 6th *l*	5.	Third *l* 6th *l*	Oct.
Sixth *l* Oct.	5.	Fourth 6th *l*	15.	Fourth *l* 6th *l*	Oct.

The octave is compoſed of a fifth and fourth, or a ſixth and third, which have a variety of greater and leſſer; out of theſe are the firſt ſix harmonies compoſed: then the fifth being compoſed of the greater third and leſſer third, and the ſixth of the fourth and third; from theſe ariſe the next ſix of the table; then an octave joined to each of theſe ſix, make the laſt ſix. Of the firſt ſix in the table each has an octave, and their preference is according to the perfection of that other leſſer concord joined to the octave. In the next ſix the preference is given to the two combinations with the fifth, whereof that which has the third *g* is beſt; then to theſe two combinations with the ſixth *g*, of which that which has the fouith is beſt. The laſt ſix are not placed laſt as the leaſt perfect, but as the moſt complex, being the mixtures of the preceding twelve. They are plainly preferable to the preceding ſix, as having the ſame ingredients and an octave more.

Compound harmony adds to the ſimple harmony of one octave that of another octave. The variety of this is eaſily found out of the combinations of the ſimple harmonies of ſeveral octaves.

Harmony may alſo be divided into that of concords, where nothing but theſe are admitted; and into that of diſcords, where they are intermixed with concords.

HARMONY is ſometimes applied to a ſingle voice, when ſonorous and ſoft; or to a ſingle inſtrument, when yielding a very agreeable ſound.

HARMONY alſo denotes a certain agreement between the ſeveral parts of a diſcourſe, which renders the reading thereof agreeable.

HARMONY, in architecture, an agreeable relation between the parts of a building.

HARMONY, in painting, both in the compoſition and colours of a picture: the former denotes the connexion between the figures, with reſpect to the ſubject of the piece; in the colouring it denotes the agreeable mixture of different colours. M. de la Chambre derives the harmony of colours from the ſame proportions as that of ſounds. On this principle he lays down green as the moſt agreeable colour correſponding to the octave; red to a fifth; yellow to a fourth, &c.

HARMONY *of the Spheres*, a ſort of muſic much talked of by many of the philoſophers and fathers, ſuppoſed to be produced by the ſweetly tuned motions of the ſtars and planets.

Pre-eſtabliſhed HARMONY, a celebrated ſyſtem of M. Leibnitz, whereby he accounts for the communication between the ſoul and body.

Philoſophers univerſally held, that the ſoul and body act phyſically on each other. Des Cartes firſt ſhewed that the heterogeneity of their nature did not admit of ſuch real union, and that they could only have an apparent one, of which God is the mediator. M. Leibnitz, unſatisfied with either of theſe hypotheſes, eſtabliſhes a third. A ſoul is to have a certain ſeries of thoughts and deſires; a body, which is only a machine, is to have a certain ſeries of motions, that are determined by the combination of its mechanical diſpoſition with the impreſſions of external objects.

If now a ſoul and body be ſo framed that the whole ſeries of deſires and motions of each exactly correſpond, this ſoul and body will have a relation to one another, not by any actual union, but by the conſtant and perpetual correſpondence between the actions of both. Now God puts together this ſoul and body, which had ſuch an antecedent correſpondence, ſuch a pre-eſtabliſhed harmony. And ſo of other ſouls and bodies that have been or ever will be joined.

The ſame principle he extends to the kingdoms of nature and grace, to account for the apparent communication betwixt them, and to make phyſical and moral evil correſpond. See *Leibn. Eſſais de Theodicée.*

HARNESS, the furniture put upon a horſe to draw in a coach, or other wheel carriage.

HARNESS-GALLS, ſwellings or ſoreneſs on the breaſts of coach horſes, occaſioned by the galling of the harneſs, eſpecially in rainy weather.

To cure this, firſt ſhave off the hair about the ſore very cloſe, and rub the whole breaſt with a lather of water and black ſope; then waſh that part of the breaſt which is uſually covered with the petrel, with ſalt-water, ſuffering it to dry of itſelf. If the hardneſs of any part of the harneſs occaſions the galling, take it away, or cover it with little bolſters.

HARP, a muſical inſtrument of the ſtring-kind, of a triangular figure, and held upright between the legs to be played upon with the fingers or nails.

The word is variouſly derived; ſome derive it from the High Dutch *harpff*; others from the Saxon *herrpa*; both ſignify the ſame thing.

Bell HARP, a muſical inſtrument of the ſtring-kind; thus called from the common players upon it ſwinging it about as a bell on its biaſs.

It is about three feet long; its ſtrings, which are of no determinate number, are of braſs or ſteel wire, fixed at one end, and ſtretched acroſs the ſound-board, by ſcrews fixed at the other end. It takes in four octaves, according to the number of ſtrings, which are ſtruck only with the thumbs, the right hand playing the treble, and the left the baſe; and in order to draw the ſound the clearer, the thumbs are armed with a little wire-pin. This may perhaps be the lyra or cythara of the ancients; but we find no mention of it under the name it now bears, which muſt be allowed to be modern.

HARPIES, *Harpyæ*, ἁρπυιαι, in antiquity, rapacious impure ſorts of monſters, of the bird-kind, deſcribed by Virg. Æn. III. The ancients looked on the harpies as a ſort of genii.

There were three harpies, Aello, Ocypete, and Celœno; which laſt Homer calls Pedarge.

HARPINEER, or HARPONEER, the perſon who manages the harping-iron.

HARPINGS. See the article SHIP-BUILDING.

HARPING-IRON, or HARPOON, a large ſpear or javelin, made of forged iron, and five or ſix feet long; it is faſtened to a line, and uſed in the whale fiſhery.

HARPSICHORD, the moſt harmonious of all the muſical inſtruments of the ſtring-kind. It is played on after the manner of the organ, and is furniſhed with a ſet and ſometimes with two ſets of keys; the touching or ſtriking of theſe keys move a kind of little jacks, which alſo move a double row of chords or ſtrings, of braſs or iron, ſtretched over four bridges on the table of the inſtrument.

HARRIER, a kind of hound, endowed with an admirable gift of ſmelling, and very bold in the purſuit of his game.

There are ſeveral kinds of harriers; ſome being for the hare, the fox, the wolf, hart, weaſel, badger, &c.

HARROW, in agriculture, an inſtrument uſed by huſbandmen to break the clods of earth, and to draw the ground over the ſeed when ſown. It is a ſort of wooden drag, made in form of a ſquare, with large iron teeth, or tines, not unlike thoſe of a horſe. See HORSE.

HART, a ſtag, or male deer, in the ſixth year. See STAG and CERVUS.

HART, among ſailors, a ſort of dead-eye with only one hole in it, uſed to draw tight the ſtays. See DEAD-EYE and STAY.

HART-ROYAL, one that has been hunted by the king or queen, and eſcaped with life; in which caſe proclamation is uſually made, that none kill or offend him, as being a hart-royal proclaimed.

HART'S HORNS, *Cornua Cervi*, in pharmacy, the whole horns of the common male deer, as ſeparated from the head, without farther preparation.

The chemical analyſis of hart's horn is ſufficiently known: it yields a water highly impregnated with a volatile ſalt, which is called ſpirit of hart's horn, with a fetid oil, and a volatile ſalt by the common diſtillation in a retort. The remainder in the bottom of the retort, after the diſtillation is finiſhed, is black; but on being calcined in an open fire, it becomes white and friable, and is what is kept in the ſhops under the name of burnt hart's horn. Beſide theſe preparations, we uſe the thin ſhavings of the horns, which, on long boiling in water, become a jelly: this jelly is nutritive and ſtrengthening; it is ſometimes given in diarrhœas; but a decoction of burnt hart's horn in water is more frequently uſed for this purpoſe, and is what is called hart's horn drink.

The ſalt of hart's horn is a great ſudorific, and is given in fevers of many kinds with great ſucceſs; the ſpirit has the ſame and all the other virtues of volatile alkalis, and is uſed to bring people out of faintings by its pungency, on holding it under their noſe, and at the ſame time pouring ſome drops of it in water down the perſon's throat.

HARVEST, the time or ſeaſon that the corn is ripe and fit to be reaped and taken into barns.

HARVEST-FLY, in zoology, a large four-winged fly of the cicada kind, very common in Italy, and erroneouſly ſuppoſed to be a graſs-hopper. See CICADA.

HASSIDEANS, or ASSIDEANS, an application given to thoſe Jews who reſorted to Mattathias, to fight for the law of God, and the liberties of their country.

HASTA, among medalliſts, a kind of javelin, unſhod or headed with iron; or rather an ancient ſort of ſcepter, longer than ordinary, occaſionally given to the gods.

HASTATED LEAF, among botaniſts, one reſembling the head of an halbert.

HAT, a covering for the head, chiefly made of hair, wool, &c. worked, fulled, and faſhioned to the figure of the head, and worn by the men throughout the weſtern part of Europe.

Hats are ſaid to have been firſt ſeen about the year 1400; at which time they became of uſe for country wear, riding, &c.

F. Daniel relates that, from the reign of Charles VI. 1449, the uſe of hats and caps is to be dated, which then began to take place of chaperoons and hoods. In proceſs of time the cuſtom paſſed from the laity to the clergy; but this was looked upon as a crying abuſe, and ſeveral regulations were publiſhed to prohibit it, enjoining the

to keep to the uſe of chaperpons made of black cloth with decent cornets faſtened to their hats, and this upon pain of ſuſpenſion and excommunication. It is true, the uſe of hats is ſaid to be of a longer ſtanding among the eccleſiaſtics of Brittany by two hundred years; but theſe were no other than a kind of caps, whence aroſe the ſquare cap now uſed in colleges.

Method of making HATS.—Hats are made either of wool, or the hair of divers animals, as the beaver, hare, rabbit, camel, &c. The proceſs is much the ſame in all. The fineſt hats are made of the pure hair of the beaver; women tear off the long hair with a knife, like a ſhoemaker's knife, and the ſhort hair they ſcrape off with another kind of knife: then they mix one third of dry caſtor to two thirds of old coat, which is a ſkin that has been worn ſome time by the ſavages. This ſtuff, ſo mixed, is carded and weighed out into parcels, according to the ſize and thickneſs of the hat intended: then each parcel is teazed with the bow-ſtring to purify it from all filth, and to make the ſtuff fall preciſely together, which is the moſt difficult part of the work. Thus they form hats of an oval figure, ending at top in an acute angle. With what ſtuff remains they ſtrengthen them where they happen to be ſlender. They purpoſely make them thicker in the brim near the crown, than towards the circumference, or crown itſelf. They next harden the hats into cloſer flakes, by preſſing down the hardening leather upon them; after which they are carried to the baſon, upon which, laying one hat at a time, they ſprinkle it over with water, and mould it: the heat of the fire, the water, and the preſſing, embody the ſtuff into a ſlight airy felt. The maker, having turned up the edges of this felt round the mould, lays it by and takes another, which when reduced to the ſame conſiſtence and form, he joins them together, ſo as to meet in an angle at top, making only one conical cap.

The next proceſs is to remove the hat to the receiver, or trough, upon the plank or ſloping ſide of which the baſoned hat is laid, being firſt dipped in the kettle: here the hatter rolls and unrolls it, one part after another, firſt with the hand, and then with a little wooden roller, dipping it from time to time for four or five hours, before it can be properly fulled: in which violent labour the workmen have their hands guarded with thick leather, called gloves. A hat thus wrought is reduced to a proper ſhape on the block tied down by a commander, and all under this ſtring is left for the brim; then it is ſet to dry; and when dry enough, it is ſinged by holding it over a flare of ſtraw, &c. then pounced to take off the coarſer nap; then they uſe the ſeal-ſkin; and, laſtly, card it to raiſe the fine cotton; then fitting it to the block, they tie it, cut round the edges, and ſend it to the dyer's, who boils it in a copper that holds between ten and twelve dozen, with a dye of logwood, verdigriſe, copperas, alder-bark, galls, and ſumac, for three quarters of an hour at a time for ten or twelve times ſucceſſively, taking every hat out after each boiling. The dyer returns it to the maker, who hangs it to dry in the roof of a ſtove, under which is a charcoal fire; and thus prepares it for ſtiffening, which is done with melted glue, or gum ſeneca, ſmeared over it with a bruſh, and rubbed in with the hand; then ſpreading a cloth over the ſteaming baſon, and ſprinkling it with water to raiſe a ſtrong ſteam to force in the ſtiffening, it is placed thereon brim downwards; and when it is moderately hot, the workman ſtrikes gently on the brim, with the flat of his hand, to make the jointings incorporate, turning it this way and that, ſetting it at laſt on the crown: then it is put on the block, bruſhed and ironed on the ſtall-board, and thus finiſhed ready to be lined.

HAT is alſo uſed in a figurative ſenſe, to ſignify the dignity of a cardinal, or a promotion to that dignity.

HATS are alſo made for women's wear, of chips, ſtraw, or cane, by platting, and ſewing the plats together; beginning with the center of the crown, and working round till the whole is finiſhed. Hats for the ſame purpoſe are alſo wove and made of horſe-hair, ſilk, &c.

HATCHEL, or HITCHEL, a tool with which flax and hemp are combined into fine hairs. It conſiſts of long iron-pins, or teeth, regularly ſet in a piece of board.

There are ſeveral ſorts of hatchels, each finer than the other, with which flax and hemp are prepared for ſpinning. See FLAX and HEMP.

HATCHES, or HATCH-WAYS, certain holes in the decks of a ſhip, through which the cargo paſſes into the hold and lower apartments: hatches are alſo the covers which lie over theſe holes.

HATCHET, a ſmall light ſort of an ax, with a baſil-edge on its left ſide, and a ſhort handle, as being to be uſed with one hand.

Hatchets are uſed by various artificers, and more particularly in hewing of wood.

HATCHING, the action whereby fœcundated eggs, after a proper time of incubation, exclude their young.

The learned M. Reaumur has obliged the world with an ingenious treatiſe on the method of hatching chickens by an artificial heat.

HATCHING, or HACHING, in deſigning, &c. the making of lines with a pen, pencil, graver, or the like; and the interſecting or going acroſs thoſe lines with others drawn a contrary way, is called counter-hatching. The depths and ſhadows of draughts are uſually formed by hatching,

Hatching is of ſingular uſe in heraldry, to diſtinguiſh the ſeveral colours of a ſhield, without being illuminated: thus, gules or red is hatched by lines drawn from the top to the bottom; azure, by lines drawn acroſs the ſhield; and ſo of other colours. See the articles GULES, AZURE, &c.

HATCHMENT, in heraldry, a name ſometimes uſed for an atchievement, or eſcutcheon over a gate, door, or on the ſide of an houſe.

HATCHMENT alſo ſignifies the marſhalling of ſeveral coats of arms in an eſcutcheon. See the article MARSHALLING.

HATTOCK, a ſhock of corn containing twelve ſheaves: others make it only three ſheaves laid together.

HAVEN, a ſea-port or harbour. See the article HARBOUR.

HAVER, a term uſed by country people for oats.

HAUNCH, or HANCH, the hip, or that part of the body between the laſt ribs and the thigh.

HAUNT, among ſportſmen, the place to which game are accuſtomed to reſort: among hunters, it is the walk of a deer, or the place of his ordinary paſſage.

HAUTBOY, a muſical inſtrument of the wind kind, ſhaped much like the flute, only that it ſpreads and widens towards the bottom, and is ſounded through a reed. The treble is two feet long; the tenor goes a fifth lower, when blown: it has only eight holes; but the baſs, which is five feet long, has eleven.

HAW, in botany, &c. a ſort of berry, the fruit of ſeveral ſpecies of meſpilus, thence denominated haw-thorns. See MESPILUS.

HAW, in farriery, is a ſwelling and ſponginеſs that grows in the inner corner of the eye of a horſe, ſo large ſometimes as to cover a part of the eye.

The method of curing it is eaſily performed by cutting part of it away; but the farriers are apt to cut away too much: the wound may be dreſſed with honey of roſes; and if a fungus or ſpongy fleſh ariſes, it ſhould be ſprinkled with burnt allum, or touched with blue vitriol.

HAWK, a ſynonymous term with falcon, though, by ſome, reſtrained to the leſſer ſort of falcons. See FALCON.

HAWKER, in commerce, a pedlar, or perſon that goes about the country ſelling wares: this name is ſaid to ariſe from their uncertain wandering, like perſons who with hawks ſeek their game where they may find it.

HAWKING, the exerciſe of taking wild-fowl by means of hawks.

HAWSE, in naval architecture, that part of a ſhip's bow through which the cable paſſes, and is drawn into and let out of the ſhip.

HAY, any kind of graſs, cut and dried, for the food of cattle.

Whatever uplands are deſigned to be mowed for hay, are to be ſhut up in the beginning of February, and no cattle ſuffered to come upon them afterwards; but the

meadows and marſh lands, where the graſs grows quicker, need not be ſhut up till April, except the ſpring be bad; and many farmers feed thoſe meadows which are in danger of overflowing till the firſt of May, and then ſhut them up for mowing.

In ſpring, the ſtones, ſticks, and all other kinds of foulneſs that lie upon the land, are to be picked up, and the mole-hills all levelled and ſpread, becauſe they hinder the mowers. If the meadows lie any thing uneven, or if they have been trodden down in winter, they ſhould be rolled all over with a large wooden roller; the mowers will then be able to cut much cloſer; for this, and the quantity of the hay, will very well anſwer the trouble.

The time of mowing the graſs muſt be proportioned to its ripeneſs; nothing can be more prejudicial to the crop, than the cutting it too ſoon, becauſe the ſap is not then fully come out of the root; and ſuch graſs, when dried into hay, ſhrinks up almoſt into nothing. It is very wrong alſo to let it ſtand too long, for, when the ſeed has been ripened, and is ſhed, the moiſture of the ſap all dries away out of the ſtalks, and they become no better than ſo much ſtubble; as is plainly ſeen in thoſe graſſes which grow in hedges, and, not being moved, die away after they have perfected their ſeeds, and become taſteleſs and very different from hay. The middle or latter end of June is the general ſeaſon for mowing; and the red flowers of the honey-ſuckle beginning to wither, generally give the farmer notice that the time is coming on. But he may be more aſſured of this, by the drops or heads of the graſs looking full, bending downward, and looking brown; it is then in the proper ſtate to be cut down.

If there is great plenty of the hay, and it lie thick in the ſwath, the hay-makers ſhould follow the mowers, and turn the ſwaths, as they cut them, unleſs there ſeems danger of wet weather; but in that caſe it is better to let them lie in the ſwath. At night it muſt be made up into little cocks, and theſe in the morning muſt be ſpread and turned, ſo that the other ſide may wither. After this it is to be made into ſmall cocks again, and the next day it is to be ſpread again, and drawn into long rows, which they call winrows. From theſe it is to be made up into large cocks after a little drying; and theſe large ones, if any wet comes, are to be ſpread open once again before they are carried in.

Mowing of land too often, or continuing it too long, is a very great prejudice to it, unleſs it have the advantage of being fed and renewed by land-floods at times. The farmer who has not this advantage to his lands, ſhould feed them once in two or three years, inſtead of making hay from them, unleſs he chuſes to lay on manure conſtantly to keep them in heart. Feeding the hay lands is the ſame ſort of reſpite that fallowing is to corn lands, both very neceſſary and advantageous.

Saint-foin HAY is of ſeveral ſorts, which may be diſtinguiſhed by the following terms, viz. 1. The virgin. 2. The bloſſomed. 3. The full grown. And 4. The threſhed hay. The firſt of theſe is beyond compariſon the beſt. It muſt be cut before the bloſſoms generally appear; for when it ſtands till it is full blown, the moſt ſpirituous and nouriſhing parts of its juice are ſpent, the ſap is much impoveriſhed, and the ſaint-foin can never recover that richneſs it had in its virgin-ſtate. But this fine hay cannot well be had of uncultivated ſaint-foin, becauſe that may not be much above an handful high when it is in a condition to be cut; it would then make a very light crop, and would be a great while before it ſprang up again; but the rich will have two or three tuns to an acre, and ſpring again immediately for a ſecond crop; ſo that little or none in quantity would be loſt by ſo great an improvement of its quality.

The ſecond ſort is that cut in the flower, which, tho' much inferior to the virgin-hay, far exceeds any other kind as yet commonly propagated in England; and if it be a full crop, it may amount to three tuns an acre. This is that ſaint-foin which is commonly made, and the larger it is, the more nouriſhing it is for horſes.

The next ſort of ſaint-foin is the full grown, cut when the bloſſoms are gone, or going off: this alſo is good hay, though it falls ſhort by many degrees of the goodneſs of the other two ſorts: but it makes a greater crop than either of them, becauſe it grows to its full bulk, and ſhrinks little in drying.

The laſt ſort is the threſhed hay, which when not damaged by wet weather, has been found more nouriſhing to horſes than coarſe water-meadow hay; and, when it is cut ſmall by an engine, is good for cattle, and much better than the chaff of corn. The beſt time to cut it, is when the greateſt part of the ſeed is well filled; the firſt-blown ripe, and the laſt-blown beginning to be full.

The goodneſs of the hay depends greatly upon the manner of ordering it. The beſt hay in all England is made of ſaint-foin, without ever ſpreading it. This method, though it be longer before it be finiſhed, coſts leſs labour than the other. If ſaint-foin be laid up pretty green, it will take no damage, provided it be ſet in ſmall round ricks, with a large baſket drawn up in the middle of each, to have a vent-hole through which the ſuperfluous moiſture of the hay may tranſpire. As ſoon as its heating is over, theſe ricks ought to be thatched; and all ſaint-foin ricks, that are made when the hay is full dried in the cocks, ought to be thatched immediately after the making them. That which is laid up moſt dried, will come out of the rick of a green colour; but that which has been much heated in the rick, will be brown.

The ſeed affords the owner another opportunity of making a profit of his ſaint-foin: but this, if the hoeing huſbandry were general, would not be vendible in great quantities for planting; becauſe the ordinary crop of an acre will produce ſeed enough to drill an hundred acres, which would not want planting for a long time. The other uſe then of this ſeed is for provender; and it has been affirmed by ſome, who have made trials of it, that three buſhels of good ſaint-foin ſeed given to horſes, will nouriſh them as much as four buſhels of oats; and when well ordered, it is ſo ſweet that moſt ſorts of cattle are greedy of it.

HAY-BOTE, in law, a liberty to take thorns, and other wood, to make and repair hedges, gates, fences, &c. by a tenant for life or years.

HAY-BOTE is alſo taken for wood for the making of rakes and forks, uſed in making hay.

HAYWARD, the perſon who keeps the common herd or cattle of a town.

He is appointed by the lord's court, and his office is to ſee that the cattle neither break nor crop the hedges of incloſed grounds; he is alſo to look to the fields, and impound cattle that commit treſpaſs therein.

HAZARD, a game on dice, without tables, is very properly ſo called, ſince it ſpeedily makes a man, or ruins him.

It is played with only two dice; and as many may play at it as can ſtand round the largeſt round table. It is certainly one of the moſt bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has reſolution enough to leave it off in time. See CHANCE and GAMING.

HAZLE, *Corylus*, in botany. See CORYLUS.

Witch-HAZLE, a name ſometimes given to the elm. See ELM.

HAZLE-EARTH, in agriculture, a moderately compact earth, much approaching to the nature of the chiefly ſoil, and indeed properly a ſpecies of it, but always containing a large quantity of reſin-coloured ſand.

HEAD, *Caput*, the uppermoſt or foremoſt part of the body of an animal. When viewed on the outſide, it is divided into the hairy ſcalp and the face. The hairy ſcalp covers the upper part of the os frontis, the ossa parietalia, the os occipitis, and the upper and lower portions of the temporal bones. The uppermoſt part of the hairy ſcalp is termed the vertex or fontanella; the back part, occiput; the lateral parts, the temples. See CRANIUM.

HEAD-ACH, *Cephalagia*, a very painful ſenſation in the nervous membranes of the head, proceeding from various cauſes, and frequently accompanied with a variety of troubleſome ſymptoms, according to its different degree and ſituation.

As the cauſes of this diſorder are various, they ought to be carefully diſtinguiſhed and enquired into, becauſe in removing them the whole method of cure in a great meaſure

measure conſiſts: but in general the intentions of cure in this diſorder are theſe following.

Firſt, if the blood and humours are impetuouſly conveyed to the head, and remain there, they are partly to be derived to the more ignoble parts, and partly to be diſcuſſed by proper remedies.

Secondly, the ſpaſmodic ſtrictures of the membranes of the head, generally produced by an acrid cauſtic matter, are to be relaxed, that the fluids, whoſe progreſſive motion through the membranes was by this means hindered, may now circulate with the greater freedom.

Thirdly, the material cauſe of the diſorder, which is peccant with reſpect to its quality, is to be corrected and gently evacuated through proper emunctions. And,

Laſtly, in order to prevent a relapſe, the whole head and nervous ſyſtem are to be corroborated by proper remedies, and more eſpecially by a well choſen diet and regimen.

If the cauſe of the pain is too large a quantity of blood violently propelled to the head, by the ſpaſm of the lower parts, no remedy affords a more inſtantaneous relief than veneſection, which ought to be performed as near the part affected as is poſſible, in order to make the more effectual derivation, under the tongue, for inſtance, in the forehead, or in the external jugular veins, or by the application of leeches behind the ears; but with this caution, that if the body is plethoric, or too turgid with blood, a vein is to be previouſly opened at the ancles, and the next, or the ſecond day after, a vein is to be breathed about the head. It is alſo adviſable, before this ſtep is taken, to evacuate the contents of the inteſtines; which is commodiouſly, and to the great relief of the patient, effected by the commonly family clyſters, or by infuſions of manna and rhubarb, with an addition of ſome aperient ſalt, ſuch as cream of tartar, or the Sedlitz ſalt.

In order to check the too violent orgaſm and tumultuous commotion of the redundant and effervеſcent blood, it is proper to exhibit a gentle diaphoretic and correcting mixture, prepared of the waters of lime flowers, lilies of the valley, elder, black cherries, with an addition of a proper quantity of diaphoretic antimony, purified nitre, calcined hart's horn, cinnabar, and ſyrup of white poppies. Externally a diſcutient and correcting epithem is to be applied, with a double linen cloth, to the forehead and head. The epithem, for this intention, may be prepared in the following manner:

Take of the vinegars of roſes and rue, each one ounce and a half; of the ſpirit of roſes two drams, in which ſix grains of camphire have been diſſolved; of purified nitre two ſcruples; of the oil of rhodium fifteen drops.

Or the following emulſion may be uſed with conſiderable ſucceſs.

Take of the kernels of peaches, and of bitter almonds, each half an ounce; of white poppy ſeeds two drams; of the waters of roſes, elder flowers, and black cherries, each two ounces; make into an emulſion, to which add of nitre half a dram, of camphire five grains diſſolved in oil of ſweet almonds: mix all together.

But another and quite different method of cure is neceſſary, if a pain, which generally continues for a conſiderable time, and is accompanied with a torpor and ſenſe of weight, is produced by a quantity of viſcid and peccant ſerum, ſtagnating within or without the veſſels of the membranes of the brain; in which caſe neither venections, nor the milder laxatives, are ſufficiently efficacious; ſo that it is proper to exhibit ſome more efficacious medicines, which have at once a power of diſſolving the thick and glutinous humours, and expelling the contents of the inteſtines: both theſe intentions are excellently anſwered by the following pills.

Take of pure gum ammoniac, ſagapenum, the beſt myrrh, roſated aloes, extract of black hellebore, reſin of jalap, mercurius dulcis, and prepared cinnabar, each half a dram; of the extract of ſaffron, of the powder of caſtor, and of the ſalt of amber, each fifteen grains: mix it up into a maſs; out of every ſcruple of which make twelve pills, ſix of which may be taken at night, and the remaining ſix in the morning.

The patient is at this time to abſtain from all aliments, except weak broths. When three days are expired, the ſame remedy may be repeated. When the peccant ſerum is by means of theſe pills ſufficiently evacuated, we are to have recourſe to ſuch medicines as corroborate the veſſels, reſtore the tone, and are at the ſame time diuretic.

HEAD-MOULD-SHOT, a diſeaſe in children, wherein the ſutures, generally the coronal, have their edges ſhot over each other, ſo as to compreſs the internal parts. This diſeaſe uſually occaſions convulſions, and admits of no cure, unleſs room could be given by a divulſion of the ſutures. This diſorder is oppoſite to the horſe-ſhoe head. See the article HORSE-SHOE-HEAD.

HEAD is alſo uſed for the top or extremity of any thing; thus we ſay, the head of a tree, the head of a bone, the head of a nail, &c.

HEAD, in architecture, an ornament of carved work, or ſculpture, frequently ſerving as the key of an arch, or platband, on other occaſions.

Theſe ſort of heads uſually repreſent ſome of the divinities, virtues, ſeaſons, ages, &c. with their attributes, as a thunderbolt for Jupiter, a diadem for Juno, a trident for Neptune, a crown of ears of corn for Ceres, a helmet for Mars, a caduceus for Mercury, &c.

The heads of beaſts are alſo uſed in places ſuitable, as an horſe's head for an equery; a deer's or boar's head, for a park or foreſt; a dog's head for a kennel; a bullock's, or ſheep's, for a ſhambles or market-houſe. In the metopes, friezes, and other parts of certain antique Doric temples, we ſee repreſentations of bullocks, or rams-heads, as a ſymbol of the ſacrifices offered there.

HEAD, in heraldry. The heads of men, beaſts, or birds, are very frequent in armoury, and borne either full-faced, looking forward, or ſide-faced in profile, when only one half of the face appears, which differences ought to be mentioned in blazoning, to avoid miſtakes; as a head, or heads fronting; or a head, or heads ſide-faced, or in profile: thus, Vert, a chevron gules, between three Turks heads couped ſide-faced proper, is borne by the name of Smith. And again, Or, a croſs gules, between four blackmoors heads, couped at the ſhoulders proper, is borne by the name Juxon. As the head is the principal part of the body, ſo it is of courſe the nobleſt bearing.

HEAD, among huntſmen, is uſed for the horns of a deer, as a hart, buck, &c. See ANTLERS, ROYALS, CROCHES, &c.

HEAD, in the military art. Head of a work is the front of it next the enemy, and fartheſt from the place, as the front of a hornwork is the diſtance between the flanked angles of the demi-baſtions; the head of a double tenaille is the ſaliant angle in the middle; and the two other ſides which form the re-entering angles. See the article FRONT.

HEAD, in painting, ſculpture, &c. a repreſentation of that part of the human body, whether in colours, draught, or creux: if taken from the life, or ſuppoſed to bear a juſt reſemblance to the perſon, it is more properly called portrait. See PORTRAIT.

HEAD-BOROUGH, the perſon who is chief of the frank-pledge in boroughs, or who anciently had the government within his own pledge. See the article FRANK-PLEDGE.

HEAD-BOROUGHS, at this time, are a kind of conſtables. See CONSTABLE.

HEAD-LAND, in huſbandry, is taken to ſignify the upper-part of land left for the turning of the plough.

HEAD-TIN, in metallurgy, a preparation of tin-ore toward the fitting it for working into metal. When the ore has been pounded and twice waſhed, that part of it which lies uppermoſt, or makes the ſurface of the maſs in the tub, is called head-tin: this is ſeparated from the reſt, and after a little more waſhing becomes fit for the blowing-houſe.

Moor's HEAD is underſtood of a horſe with a black head and feet; the body being uſually of a roan colour. Among engineers a Moor's head is uſed for a kind of bomb or granado ſhot out of a cannon. Among chemiſts it is a cover, or capital, of an alembic; having a long neck to convey the vapours raiſed by the fire into a veſſel, which ſerves as a refrigeratory. See ALEMBIC.

Dragon's

Dragon's HEAD, in aſtronomy, &c. is the aſcending node of the moon, or other planet. See the article NODE.

HEADS, a term uſed by builders for that kind of tile which they uſe to lay at the eaves of a houſe; being the full breadth of a common tile, and but half a tile in length. See the article TILE.

HEALING, in architecture, the covering a roof with lead, tiles, ſlate, or the like.

HEALTH, *Hygieia Hygeia*, a proper diſpoſition of the body, and all its parts for performing their reſpective functions; and this conſiſts in a due connexion. It is likewiſe applied to the mind, and then it means a juſt diſpoſition of the rational powers and paſſions to perform their proper actions; and this, in a great meaſure, depends on bodily health.

The preſervation and reſtoration of health conſtitute the objects of the arts of medicine. The continuance of health depends principally on the ſix non-naturals, air, food, exerciſe, the paſſions, evacuation and retention, ſleeping and waking. The ancients erected a goddeſs, to whom they ſuppoſed the care of health to belong: the Greeks worſhipped her under the name Υγιεια, and the Romans under that of Salus. Her temple at Rome was on the Mons Quirinalis, where ſhe had a ſtatue crowned with medicinal herbs.

She is repreſented in medals with a ſerpent ſtretched on her left arm, and holding a patera to it with the right: ſometimes ſhe has an altar before her with a ſerpent twiſted round, raiſing its head to take ſomething out of the ſame; with the inſcription SAL. AUG.

HEAM denotes in animals the ſame as after-birth or ſecundines in women.

HEARING, *Auditus*, one of the external ſenſes, being the act of faculty of perceiving ſounds; its organ is the ear, particularly the auditory nerve diffuſed through it; its objects are certain vibrations of the air. See the article SOUND.

The ear and its ſeveral membranes, nerves, canals, &c. are vehicles for the reception, modification, and tranſmiſſion of ſound to the brain, which is the ſeat of this ſenſe. See EAR.

HEARSE, among ſportſmen, a hind of the ſecond year of her age. See HIND.

HEART, *Cor*, in anatomy, a muſcular body ſituated in the cavity of the thorax, on the anterior part of the diaphragm, between the two laminæ of the mediaſtinum. It is ſomewhat conical, flatted on the ſides, round at the top, and oval at the baſis; this laſt is accompanied with appendices, called auriculæ, and by large blood-veſſels; and all theſe are included in a membranous capſula, named pericardium.

It is hallow within, and divided by a ſeptum, which runs between the edges into two cavities; one of which is thick and ſolid, called the left ventricle; the other thin and ſoft, termed the right ventricle; though in their natural ſituation, the right ventricle is placed more anteriorly than the left. Each ventricle opens at the baſis by two orifices, one of which anſwers to the auricles, the other to the mouth of a large artery; one of which may be termed the auricular orifice, the other the arterial orifice. The right ventricle opens into the right auricle, and into the trunk of the pulmonary artery; the left into the left auricle, and into the great trunk of the aorta. At the edges of theſe orifices are ſeveral moveable pellicles, called valves, of which ſome are turned inward towards the ventricles, that let the blood enter the heart, but hinder it from going out the ſame way, and are called triglochines or tricuſpides; others turned towards the great veſſels, which ſuffer the blood to go out of the heart, but hinder it from returning, and are called ſemi-lunares or ſigmoidales. The tricuſpides of the left ventricle are likewiſe termed nitrales.

The inner ſurfaces of the ventricles have thick fleſhy productions called columnæ. To the extremities of theſe columnæ or pillars are faſtened ſeveral tendinous cords, the other ends are joined to the tricuſpides. There are likewiſe other ſmall, ſhort, tendinous ropes along both the edges of the ſeptum, in an obliquely tranſverſe ſituation forming a kind of net-work.

The cavities of the ventricles are ſmall deep foſſulæ, near each other, with ſmall prominent interſtices between. The greateſt part of the foſſulæ are orifices of the venous ducts.

The fleſhy fibres of the heart, eſpecially thoſe of the right ventricle, are either bent into arches, or folded into angles, the latter being longer than the former. The middle of theſe arches, and the angles of the folds, are turned towards the apex of the heart; and the extremities of the fibres toward the baſis. Theſe fibres not only differ in length, but in their directions, which are very oblique in all, but much more ſo in the long or folded fibres than in the ſhort ones.

Each ventricle is compoſed of its proper diſtinct fibres; but the left has many more than the right. By carefully unravelling all the fibres of the heart, we find it to be made up of two bags contained in a third.

The tubes which croſs tranſverſely are much more numerous than thoſe which croſs longitudinally; which will ſerve to rectify the falſe notion about the motion of the heart, that it is performed by a contortion like a ſcrew; that the heart is ſhortened in the time of contraction, and lengthened in dilatation.

The tricuſpidal valves of the right ventricle are three triangular productions, very ſmooth on that ſide next the auricle, and on the ſide next the ventricle ſeveral membranous and tendinous expanſions, and their edges notched. The valves of the auricular orifice of the left ventricle are of the ſame ſtructure, and but two in number.

The ſemi-lunar valves are ſix in number, three belonging to each ventricle, ſituated at the mouths of the great arteries, and may be properly enough called valvulæ arteriales.

The auricles are muſcular bags, ſituated at the baſis of the heart, one towards the right ventricle, the other towards the left, and joined together by an inner ſeptum and external communicating fibres, much like the ventricles; one of them being called the right auricle, the other the left. They are very uneven on the inſide, but ſmoother on the outſide, and terminate in a narrow, fat, indented edge, like a cock's comb.

The right auricle is larger than the left, and it joins the right ventricle by a common tendinous opening. It has two other openings united into one, and formed by two large veins, which meet and terminate there, almoſt in a direct line, called vena cava, ſuperior and inferior; the notched edge of this auricle terminates obliquely in a kind of obtuſe point, which is a ſmall production of the great bag, and is turned towards the middle of the baſis of the heart.

The whole inner ſurface of the right auricle is uneven, by reaſon of a great number of prominent lines, which run acroſs the ſides of it, and communicate with each other by ſmaller lines, which lie obliquely in the interſtices between the former.

The left auricle is pretty thick and unequally ſquare, into which the four veins open that are called venæ pulmonares, and which has a diſtinct appendix belonging to it, like a third ſmall auricle.

Beſides the great common veſſels, the heart has ſome peculiar to itſelf, called the coronary arteries and veins, as in ſome meaſure they crown the baſis of the heart. Theſe arteries, which are two in number, called the right and left coronaries, go out from the beginning of the aorta, and afterwards ſpread round the baſis of the heart, to the ſubſtance of which they ſend numerous ramifications. The exterior courſe of the veins is pretty much the ſame with that of the arteries; their trunk opens principally into the right auricle, by a particular orifice, furniſhed with a ſemi-lunar valve: all the coronary veſſels and their ramifications communicate with each other. The pericardium conſiſts of three laminæ, the middle and principal of which is compoſed of very fine tendinous filaments croſſing each other in different directions. The external lamina ſeems to be a continuation of the outer coat of the heart, auricles, and great veſſels.

The pericardium is cloſely connected to the diaphragm not at the apex, but exactly at that place which anſwers to the flat or lower ſide of the heart; the reſt of the heart lies upon the diaphragm without any adheſion. The external lamina, or more properly common covering, is formed by the duplicature of the mediaſtinum. The

internal lamina is perforated by an infinite number of very ſmall holes, through which a ſerous fluid continually tranſudes, in the ſame manner as in the peritonæum: ſometimes, upon diſſection, it is of a reddiſh colour, which may be owing to a tranſudation of blood through the fine membrane of the auricles.

The heart and parts belonging to it are the principal inſtruments of the circulation of the blood. The two ventricles ought to be conſidered as two ſyringes ſo cloſely joined together as to make but one body, and furniſhed with ſuckers in contrary directions to each other; ſo as that, by drawing one of them, a fluid is let in, and forced out again by the other.

The heart is made up of a ſubſtance capable of contraction and dilatation. When the fleſhy fibres of the ventricles are contracted, the two cavities are leſſened in an equal and direct manner, more according to the breadth or thickneſs, than according to the length of the heart; becauſe the number of tranſverſe fibres is much greater than that of the longitudinal ones.

The fleſhy fibres, thus contracted, do the office of ſuckers, by preſſing upon the blood in the ventricles; which blood being forced to the baſis of the heart, preſſes the tricuſpidal valves againſt each other, opens the ſemilunares, and ruſhes with impetuoſity through the arteries and their ramifications, as through ſo many elaſtic tubes. The blood thus puſhed on enters the capillary veſſels, and is from thence forced to return by the veins to the auricles, which like retirements lodge in the blood returned by the veins during the time of a new contraction, which is termed ſyſtole.

The contraction or ſyſtole ceaſes immediately; and in that time the auricles, which contain the venous blood, being contracted, force the blood through the tricuſpidal valves into the ventricles, the ſides of which are thereby dilated, and this dilatation is called diaſtole. In this manner does the heart perform the circulation, and that three different ways: the firſt and moſt univerſal kind of circulation is that by which almoſt all the arteries of the body are filled by the ſyſtole of the heart, and the greateſt part of the veins evacuated by the diaſtole.

The ſecond kind of circulation, oppoſite to the firſt, is through the coronary veſſels of the heart, the arteries of which are filled with blood, during the diaſtole of the ventricles, and the veins emptied during the ſyſtole.

The third kind is that of the left ventricle of the heart, through the venous ducts of which a ſmall quantity of blood paſſes, without going through the lungs, which is the courſe of all the remaining maſs of blood. *Winſlow.*

Explanation of plate LXXIII.

Fig. 1. The human heart ſeen in its convex part, and in a horizontal ſituation.

B, The right ventricle opening into the right auricle and into the trunk of the pulmonary artery.
C, The left ventricle opening into the left auricle and into the great trunk of the aorta.

Fig. 3 and 4 repreſent the heart in different poſitions to ſhew the fibres and orifices of the venous ducts.

A, Aſcending trunk of the vena cava.
B, The trunk of the aorta.
C, Branches of the pulmonary vein.
D, Deſcending trunk of the vena cava.
E, Part of the right auricle cut away to ſhew the different ranging of the internal fibres and venous ducts.

To find the Force of the HEART. — Let $p =$ the weight of the left ventricle, or a quantity of blood equal to th ſame weight. S = the internal ſurface of the ſame; $l =$ the mean length of the filaments of blood iſſuing from the ſame; $s =$ the ſection of the aorta; $q =$ the quantity of blood contained in the left ventricle; $t =$ the time in which the blood would be expelled from the heart, taking away the reſiſtance of the arteries, and of the blood going before; $v =$ the variable velocity with which the blood iſſuing from the heart would flow through the aorta, abſtracted from the reſiſtance; $x =$ any variable length of the aorta, deſcribed by the blood guſhing from the heart; z the time in which the length x is deſcribed.

Hence the mean variable velocity of the blood contiguous to the ventricle, or the mean velocity of the ventricle itſelf, is $= \frac{sv}{S}$, and the motion of the ventricle $= p \times \frac{sv}{S}$: the motion of the iſſuing blood is $= sv \times \overline{l + x}$; and therefore the ſum of theſe, or the power of the ventricle $= sv \times \overline{\frac{p}{S} + l + x}$: all this is evident from the common principles of mechanics. But $v = \frac{\dot{x}}{\dot{z}}$; for the velocity is always equal to the ſpace divided by the time. Now for v put its equal $\frac{\dot{x}}{\dot{z}}$, and we ſhall have $\frac{s\dot{x}}{\dot{z}} \times \overline{\frac{p}{S} + l + x}$, for the fluxion of the forces, whoſe fluent $\frac{sx}{z} \times \overline{\frac{p}{S} + l + \frac{x}{2}}$ is the required force itſelf; which, when z becomes t, and sx becomes q, will be $\frac{q}{t} \times \overline{\frac{p}{S} + l + \frac{q}{2s}}$.

In the ſame manner the power of the right ventricle will be found equal to $\frac{q}{t} \times \overline{\frac{\pi}{\Sigma} + \frac{q}{2\sigma}} + \lambda$, wherein the ſame things are ſignified by the Greek letters in the right ventricle, as by the Latin letters in the left, q and t being the ſame in both. Hence the whole force of the heart will be expreſſed by $\frac{q}{t} \times \overline{\frac{p}{S} + l + \frac{q}{2s} + \frac{\pi}{\Sigma} + \frac{q}{2\sigma}} + \lambda$.

If we ſuppoſe $p = 8$ ounces avoirdupoiſe $= 13,128$ cubic inches; $\pi = 4 = 6,564$; S $= 10$ ſquare inches; $l = 2$ ſquare inches; $\Sigma = 10$; $\lambda = 1\frac{1}{2}$; $q = 2$ ounces avoirdupoiſe $= 3,282$ cubic inches; $s = 0,4185$ ſquare inches; $\sigma = 0,583$; $t = 0''$, 1. Theſe three laſt by Dr. Keill's experiments.

By the above theorem the force of the ventricles will be equal to the motion of the underwritten weights; that is,

	Pounds	Ounces
Of the left ventricle — —	9	1
Of the right ventricle — —	6	3
Of the whole heart — —	15	4

Of which weights the velocity will be ſuch, as that a line of an inch long might be deſcribed by the ſame in one ſecond of time.

Corol. 1. As often as the pulſe becomes quicker, either the reſiſtance is leſſened, or the force of the heart is increaſed, or a leſs quantity of blood than uſual is expelled by the heart at each contraction.

2. If the pulſe becomes ſlower than uſual, either the reſiſtance is increaſed, or the power of the heart is diminiſhed, or a greater quantity of blood is thrown out of the heart.

3. When the reſiſtance is increaſed, the pulſe will neceſſarily become ſlower, or the force of the heart will be increaſed, or a leſs quantity of blood than uſual will be ſqueezed out of the heart.

4. When the reſiſtance is leſſened, either the pulſe is accelerated, or a greater quantity of blood is thrown out at every ſyſtole, or the force of the heart is diminiſhed.

5. If the force of the heart be increaſed, either the reſiſtance will neceſſarily be increaſed, or the pulſe will be accelerated, or more blood will be thrown out by the heart.

6. If the force of the heart be diminiſhed, either the reſiſtance will neceſſarily be diminiſhed, or the pulſe will become ſlower, or leſs blood will be ſqueezed from the heart.

7. When a leſs quantity of blood is diſcharged by the heart, either the pulſe will be accelerated, or the force

of the heart diminiſhed, or the reſiſtance will be increaſed.

8. When more blood is ſqueezed out of the heart, either the pulſe will become ſlower, or the force of the heart will be increaſed, or the reſiſtance will be diminiſhed.

Schol. We have contented ourſelves to eſtimate the internal ſurfaces of the ventricles ſomething near the truth, ſince it ſeems very difficult to determine them exactly, or to take account of that diminution they muſt undergo in contracting: for whether we make them twelve or eight ſquare inches, the change made in the forces would be found to be but very little: this alſo may be obſerved of the mean length of the filaments of blood. We have alſo neglected the differences by which both the arteries and their branches neareſt the heart are increaſed by ſection, as being very difficult to be eſtimated, and almoſt inſenſible; otherwiſe the force of the heart muſt be made ſomething ſmaller than is before determined.

HEAT, *Calor*, one of the qualities of the body, oppoſed to cold. Its preſence is known, and its degree meaſured by the expanſion of the air or ſpirit in the thermometer. It is properly a ſenſation excited in us by the action of fire, ſo that it is a particular modification of our minds, and not any thing exiſting in that form in the body that occaſions it. Heat, in the body that communicates it, is only motion; in the mind, a particular diſpoſition of the ſoul.

Heat, with reſpect to the effect produced on us, is eſtimated by its relation to the organ of feeling, no object appearing to be hot, unleſs its heat exceed that of our bodies.

Heat, as it exiſts in the hot body, and enables it to produce ſuch and ſuch effects on our organ, is variouſly conſidered by the philoſophers.

Ariſtotle and the Peripatetics define heat a quality or accident, whereby homogeneous things are collected together, and heterogeneous things ſeparated: but heat cannot be ſaid to do either this or that univerſally; all its effects depend on the circumſtances of application: thus, to do the ſame thing in different bodies, different degrees of heat are required; add to this, that the ſame degree of heat ſhall have oppoſite effects on different bodies.

The Epicureans and other Corpuſcularians define heat an eſſential property of fire, the ſame in reality with it, only diſtinguiſhed therefrom in the manner of our conception. Heat then, on their principles, is no other than the volatile ſubſtance of fire itſelf, reduced into atoms, and emitted in a continual ſtream from the ignited bodies; ſo as not only to warm the objects near them, but kindle them, if inflammable. In effect, theſe corpuſcles flying off from the ignited body, while yet within the ſphere of its flame, by their motion conſtitute fire; but when got beyond it, ſo as only to be perceivable by the feeling, they take the denomination of heat, as they ſtill excite that ſenſation in us.

The Carteſians, improving on this doctrine, aſſert heat to conſiſt in a certain motion of the inſenſible particles of a body, like that whereby all the parts of the human body are agitated by the motion of the heart and blood.

Our lateſt and beſt writers of experimental and chemical philoſophy differ very conſiderably about heat; the fundamental difference is, whether it be a peculiar property of one certain immutable body called fire, or whether it may be produced mechanically in other bodies, by inducing an alteration in the particles thereof.

The former tenet, which is that of Democritus, and as ancient as the ſyſtem of atoms, had given way to that of the Carteſians and other mechaniſts, but is now with great addreſs retrieved and improved by Homberg, the younger Lemery, s'Graveſande, and particularly Boerhaave. See the article FIRE.

HEAT, in geography. The diverſity of the heat of climates and ſeaſons ariſes from the different angles under which the ſun's rays ſtrike on the earth's ſurface.

It is ſhewn in mechanics, that a moving body ſtriking perpendicularly on another, acts on it with all its force; and that a body ſtriking obliquely acts with the leſs force, the more it deviates from the perpendicular. Now fire moving in right lines muſt follow the ſame law, and conſequently its action muſt be meaſured by the ſine of the angle of incidence: and hence fire, ſtriking on any obſtacle in a direction parallel thereto, has no ſenſible effect, by reaſon the ratio is almoſt infinite, that is nothing.

Hence Dr. Halley gives a mathematical computation of the effect of the ſun under different climates and ſeaſons, going on this principle, that the ſimple action of the ſun, as all other impulſes, is more or leſs forcible, according to the ſines of the angles of incidence, or to the perpendicular let fall on the plane: whence the vertical ray being put for radius, the force of the ſun on the horizontal ſurface of the earth will be to that, as the ſine of the ſun's altitude at any other time. Hence it follows, that the time of the continuance of the ſun's ſhining being taken for a baſis, and the ſines of the ſun's altitudes erected thereon as perpendiculars, and a curve drawn through the extremities of thoſe perpendiculars, the area comprized therein will be proportional to the collection of the heat of all the ſun's beams in that ſpace of time.

Hence it will alſo follow, that under the pole the collection of all the heat of a tropical day is proportionate to a rectangle of the ſine of 23 degrees and a half into 24 hours, or the circumference of a circle; that is, the ſine of 23° and $\frac{1}{2}$ being nearly $\frac{4}{10}$ of radius, as $\frac{8}{10}$ into 12 hours: or the polar heat is equal to that of the ſun continuing 12 hours above the horizon at 53° height, than which the ſun is not five hours more elevated under the equinoctial.

But whereas the nature of heat is to remain in the ſubject, after the luminary is removed, and particularly in the air; under the equinoctial, the 12 hours abſence of the ſun does but little diminiſh the motion impreſſed by the paſt action of his rays, before he riſes again: but under the pole, the long abſence of the ſun for ſix months, wherein extreme cold obtains, hath ſo chilled the air, that it cannot, before the ſun has got far towards it, be any ways ſenſible of his preſence, his beams being obſtructed by thick clouds and perpetual fogs. Add to this, that the different degrees of heat and cold in different places depend, in a great meaſure, upon the accident of ſituation with regard to mountains, vallies, &c. the firſt greatly helping to chill the air by the winds that blow over them, and which come in eddies through the adjoining levels. Mountains ſometimes have the effect of a burning mirrour on the adjacent plane, and the ſame effect is ſometimes produced from the concave or convex parts of clouds, either by refraction or reflection. And ſome take theſe to be ſufficient to produce thunder, lightning, &c.

A ſtony, ſandy, or chalky ſoil reflects moſt of the rays into the air again and retains but few, whereby a conſiderable acceſſion of heat is made to the air; as, on the contrary, black earths abſorb moſt of the rays and return few into the air.

The following table gives the heat to every 10° of lat. to the equinoctial and tropical ſun, whereby an eſtimate may be made of the intermediate degrees.

Lat.	Sun in ♈ ♎	Sun in ♋	Sun in ♑
0	20000	18341	18341
11	19696	20290	15834
20	18797	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	000
80	3473	24673	000
90	0000	25055	000

Hence are deducible the following corollaries: 1. That the equinoctial heat, when the ſun is vertical, is as twice the ſquare of the radius, which is a ſtandard to be compared with in all other caſes. 2. That, under the equinoctial, the heat is as the ſine of the ſun's declination. 3. That in the frigid zones, when the ſun does not ſet, the heat is as the circumference of a circle into the ſine of the altitude at 6: and conſequently, that in the ſame latitude, theſe aggregates of warmth are as the ſines of the ſun's declination; and at the ſame declination of the ſun

ſun, they are as the ſines of the latitudes into the ſines of the declination. 4. That the equinoctial day's heat is every-where as the co-ſine of the lat. 5. In all places where the ſun ſets, the difference between the ſummer and winter heats, when the declinations are contrary, is equal to a circle multiplied into the ſine of the altitude at ſix in the ſummer parallel; and conſequently thoſe diſferences are the ſines of lat. into the ſines of declin. 6. From the table it appears that the tropical ſun under the equinoctial has of all others the leaſt force: under the pole it is greater than any other day's heat whatever, being to that of the equinoctial as 5 to 4.

Thus all the actions of the ſun throughout the year, and that part of heat which ariſeth ſimple from the preſence of the ſun may be brought to a geometrical certainty. The heat of the ſun, for any ſmall portion of time, is always as a rectangle contained under the ſine of the angle of incidence of the ray that produces it.

HEAT, in the animal œconomy, known by the ſeveral names of natural heat, vital heat, innate heat, and animal heat, is commonly ſuppoſed to be that generated by the attrition of the parts of the blood, occaſioned by its circulatory motion, eſpecially in the arteries.

To what organs, or operations, the heat of the human body, and other animal bodies, is owing, is hitherto extremely doubtful. The opinions that at preſent prevail are, 1. That the heat of animal bodies is owing to the attrition betwixt the arteries and the blood. 2. That the lungs are the fountain of this heat. 3. That the attrition of the parts of the ſolids on one another produce it. 4. That it is owing to the mechanical attrition of the particles of our fluids. To which opinions Dr. Stevenſon of Edinburgh, adds a 5, viz. That whole proceſs by which our aliment and juices are conſtantly undergoing ſome alteration.

HEAVEN, *Cœlum*, that orb over our heads where the heavenly bodies revolve. Philoſophers, divines, and aſtronomers, lay down divers heavens, as the higheſt or empyrean heaven, the æthereal or ſtarry heaven, and the planetary heaven.

HEAVEN, among divines, called the empyrean, is the abode of God, and bleſſed ſpirits, ſuch as angels, and the ſouls of the righteous deceaſed. This in Scripture is frequently called the kingdom of heaven, the heaven of heavens, the third heaven, paradiſe, the new Jeruſalem, &c. This heaven is conceived as a place where the Deity is pleaſed to afford a more immediate view of himſelf than in the other parts of the univerſe, where he is likewiſe preſent. This makes the beatific viſion. The inſpired writers, particularly Iſaiah and St. John the divine, give us very magnificent deſcriptions of heaven, its ſtructure, apparatus, and attendance. Euſebius charges Plato with borrowing his deſcription of heaven, *in Dial. de Anima*, from the Scriptures, ſo near is the reſemblance.

The ancient Romans had a kind of heaven in their theology, called Elyſium or Elyſian fields, as the Mahometans have their paradiſe, which is very groſs, agreeable to the genius of their religion.

HEAVEN, in aſtronomy, called the æthereal and ſtarry heaven, is that immenſe region where the ſtars, planets, and comets are ranged. It is vulgarly called the firmament, though the original word uſed by Moſes, when ſpeaking of the ſecond day's creation, properly ſignifies no more than expanſe, a term adapted to the impreſſion which the heavens make on our ſenſes; whence in other parts of Scripture the heaven is compared to a curtain or tent to dwell in.

Deſcartes, Kircher, &c. have eaſily demonſtrated this heaven not to be ſolid, but fluid, though they ſtill ſuppoſe it full, without any vacuity, and cantoned out into ſo many vortices.

Sir Iſaac Newton has abundantly ſhewn the heavens to be void of all reſiſtance, and conſequently almoſt all matter, from the planets perſiſting in their motions without any ſenſible diminution of their velocity, and the comets paſſing freely in all directions.

The ancient aſtronomers aſſumed as many heavens as they obſerved different motions therein; all which they ſuppoſed ſolid and ſpherical. Thus, there were ſeven heavens for the ſeven planets; the eighth was for the fixed ſtars, which they called firmament: Ptolemy adds a ninth, which he called the primum mobile. K. Alphonſus added two cryſtalline heavens to account for ſome irregularities in the heavenly motions; and, laſtly, an empyrean heaven was drawn over the whole for the reſidence of the Deity.

The cryſtalline heavens were ſuppoſed to have no ſtars fixed in them; they encompaſſed the inferior, ſtarry, and planetary heavens, communicating their motion thereto. The firſt ſerved to account for that ſlow motion of the fixed ſtars, whereby they advance a degree eaſtward in ſeventy years: whence the preceſſion of the equinoxes. The ſecond was to ſolve the phænomena of libration or trepidation.

Eudoxus ſuppoſed twenty-three heavens, Calippus thirty, Regiomontanus thirty-three, Ariſtotle forty-ſeven, and Fracaſtor ſeventy.

The aſtronomers did not much concern themſelves about the reality of theſe heavens, provided they ſerved to account for any of the celeſtial motions, and agreed with phænomena.

HEAVING, among ſeamen, the act of turning a windlaſs or capſtern by the help of long bars thruſt into holes or mortices cut in the bodies of them. See the articles WINDLASS and CAPSTERN.

HEAVING *a-head*, drawing the ſhip a-head by heaving in the cable, and thereby making her advance towards the anchor or other place where the cable or rope which draws her onward is faſtened.

HEAVING-DOWN, the ſame with careening. See CAREENING.

HEBDOMARY, a ſolemnity of the ancient Greeks, in honour of Apollo, in which the Athenians ſung hymns to that god, and carried in their hands branches of laurel. The word ſignifies the ſeventh day, this ſolemnity being obſerved on the ſeventh day of every lunar month.

HEBRAISM, an idiom or peculiar manner of expreſſion in the Hebrew language.

HEBREW, or HEBREW-LANGUAGE, that ſpoken by the ancient Jews, and wherein the Old Teſtament is wrote.

This appears to be the moſt ancient of all the languages in the world, at leaſt we know of none older: and ſome learned men are of opinion that this is the language in which God ſpoke to Adam in Paradiſe, and in which the ſaints will ſpeak in heaven.

The books of the Old Teſtament are the only pieces to be found, in all antiquity, written in pure Hebrew; and the language of many of theſe is extremely ſublime: it appears perfectly regular, and particularly ſo in its conjugations; indeed, properly ſpeaking, it has but one conjugation, but this is varied in each ſeven or eight different ways, which has the effect of ſo many different conjugations, and affords a great variety of expreſſions to repreſent by a ſingle word the different modifications of a verb, and many ideas which in the modern, and in many of the ancient and learned languages, cannot be expreſſed without a periphraſis.

The primitive words, which are called roots, have ſeldom more than three letters or two ſyllables.

In this language there are twenty-two letters, only five of which are uſually reckoned vowels, which are the ſame with ours, viz. *a*, *e*, *i*, *o*, *u*; but then each vowel is divided into two, a long and a ſhort, the ſound of the former being ſomewhat grave and long, and that of the latter ſhort and acute: it muſt however be remarked, that the two laſt vowels have ſounds that differ in other reſpects beſides quantity, and a greater or leſs elevation. To theſe ten or twelve vowels may be added others called ſemi-vowels, which ſerve to connect the conſonants, and to make the eaſier tranſitions from one to another. The number of accents in this language are, indeed, prodigious: of theſe there are near forty, the uſe of ſome of which, notwithſtanding all the enquiries of the learned, are not yet perfectly known. We know, in general, that they ſerve to diſtinguiſh the ſentences like the points called commas, ſemicolons, &c. in our language; to determine the quantity of the ſyllables, and to mark the tone with which they are to be ſpoke or ſung.

HEBREWS, or *Epiſtle to the* HEBREWS, a canonical book of the New Teſtament.

Though

Though St. Paul did not prefix his name to this Epiſtle, the concurrent teſtimony of the beſt authors, ancient and modern, afford ſuch evidence of his being the author of it, that the objections to the contrary are of little or no weight. His mentioning himſelf in it, as lately a priſoner in Italy, and his promiſe to viſit the Hebrews, together with Timothy, who had been releaſed from impriſonment, both denote the writer, and the time of his writing this Epiſtle, that it was juſt after the deliverance of St. Paul from his firſt trial at Rome.

The Hebrews, to whom this Epiſtle was wrote, were the believing Jews of Paleſtine, and its deſign was to convince them, and, by their means, all the Jewiſh converts, whereſoever diſperſed, of the inſufficiency and aboliſhment of the ceremonial and ritual law. In order to which he undertakes to ſhew, firſt, the ſuperior excellency of Chriſt's perſon above that of Moſes: ſecondly, the ſuperiority of Chriſt's prieſthood above the levitical: thirdly, the mere figurative nature, and utter inſufficiency of the legal ceremonies and ſacrifices: and, fourthly, that to forſake the Moſaical law, was not, as the Jews boldly aſſerted, to apoſtatize from God, but was their indiſpenſible duty and obligation. Theſe particulars are intermixed with proper inferences and exhortations, all tending to ſhew the Jewiſh Chriſtians the unreaſonableneſs, folly, and danger of relapſing into Judaiſm.

HECATOMB, *Hecatombe*, in antiquity, a ſacrifice of an hundred oxen, at as many altars, and by as many prieſts.

The word is Greek, εκατομβη, and derived from εκατον, an hundred, and βους, an ox, as conſiſting of an hundred bullocks; others from εκατον, an hundred, and πους, a foot, as if the ſacrifice might conſiſt only of twenty-five quadrupeds.

Pythagoras we are told ſacrificed a hecatomb to the muſes, for joy of diſcovering the demonſtration of the 47th Prop. of Euclid's firſt book.

HECKLE. See HATCHEL.

HECKLING *of Hemp and Flax*. See HEMP and FLAX.

HECTIC, or HECTIC FEVER. See *Slow* FEVER.

HEDERA, ivy, in botany. See IVY.

HEDERA TERRESTRIS, ground ivy, a genus of plants called by Linnæus glechoma. See GLECHOMA and GROUND IVY.

HEDGE, in agriculture, a fence incloſing a field or garden, made of buſhes, boughs, &c. interwoven together.

The word is Saxon, *hegge*, or *hege*, which literally ſignifies circumference or incloſure.

For quickſet hedges, hawthorn is allowed to be the beſt of all the Engliſh ſhrubs. The beſt method of raiſing this for uſe, is to put the haws into the ground as ſoon as ripe, and cover them with earth; and by the ſpring twelvemonth, the young ſhoots will be fit to tranſplant from the ſeed-plot into hedge-rows. The crab-tree is a common mixture with the hawthorn in hedges; but grows faſter than the hawthorn, and requires cutting to keep the hedge even. The young hawthorns raiſed from ſeed always thrive better than thoſe picked up wild in the fields. *Moreton's Northampt.*

The great conſideration, in making quick-ſet hedges, is to bring the plants from a worſe ſoil than that in which it is intended to ſet them. They muſt be about the thickneſs of one's thumb, well rooted and ſtrong, and muſt be planted about four or five inches out of the ground. If there be a ditch to the hedge, it ſhould be three feet wide at the top, one at the bottom, and two deep; and, if wider, then deeper in proportion.

If the bank be without a ditch, the plants ſhould be ſet in two rows at a foot diſtance below one another. The turf is to be laid with the graſs ſide downward on that ſide of the ditch on which the bank is deſigned to be made, and ſome of the beſt mould muſt be laid upon it to bed the quick; then the quick is to be laid upon it a foot aſunder, ſo that the end of it may be inclining upwards; and at equal diſtances of thirty feet, plant an aſh, oak, crab, or elm, to grow with the quick. When the firſt row of quick is laid, it muſt be covered with mould, and the turf laid upon it as before, and ſome more mould upon that; ſo that when the bank is a foot high, another row of ſets may be laid againſt the ſpaces of the lower quick. Theſe muſt be then covered as the former, and the bank is to be then topped with the bottom of the ditch, and a dry or dead hedge laid, to ſhade the under plantation. There ſhould then be ſtakes driven into the looſe earth quite down to the firm ground, at about two feet and a half diſtance from each other; oak ſtakes are accounted the beſt of all for uſe, and, the next to this, thoſe of black-thorn or ſallow. Small buſhes are to be laid below, but not too thick, only to cover the quick from being injured, as it ſhoots. *Miller's Gard. Dict.*

HEEL, in anatomy, the hind-part of the foot. See FOOT and CALCANEUM.

HEEL *of a Horſe*, the lower hinder part of the foot, comprehended between the quarters, and oppoſite to the toe.

The heel of a horſe ſhould be high and large, and one ſide of it ſhould not riſe higher than the other upon the paſtern. To recover the heels of a horſe that is hoof-bound, you ſhould take out his ſole, and keep his heels very wide, by which they will be reſtored in a month.

HEEL *of a Maſt*, the foot or lower end of it.

HEEL *of a Ship*, the hindmoſt or aftmoſt part of a ſhip's keel.

HEELING, in the ſea-language, ſtooping or inclining to one ſide, either by the preſſure of ſail at ſea, or to clean the ſhip's bottom, &c. See the article CAREEN and BOOT-TOP.

HEGIRA, in chronology, a celebrated epocha among the Arabs and Mahometans.

The word is Arabic, *hagirah*, which ſignifies flight.

The event which gave occaſion to this epocha was Mahomet's flight from Mecca; the magiſtrates of this city, fearing this impoſtor might raiſe a ſedition, expelled him on the 15th or 16th of July, in the year 622, being the fourteenth year of his aſſuming the character of prophet, and under the reign of the emperor Heraclius.

There is an earlier Hegira in the ſame year, when Mahomet and his diſciples relinquiſhed Medina. Both theſe hegira's the Mahometans call hegiratan.

HEIGHT, *Altitudo*, in geometry. See the article ALTITUDE.

HEIR, *Hæres*, in law, ſignifies a perſon who ſucceeds another by deſcent to lands, tenements, hereditamens, being an eſtate of inheritance, or an eſtate in fee; becauſe nothing paſſes by right of inheritance but in fee.

HEIR-APPARENT is a perſon ſo called in the lifetime of his anceſtor, at whoſe death he is heir at law.

HEIRESS, a female heir to one who has an eſtate in lands, &c. Stealing an heireſs, and marrying her againſt her will, was declared felony by 3 Hen. VII.

HEIR-LOOME is a word that comprehends in it divers pieces of furniture; as the firſt bed, and other things, which by the cuſtom of ſome places have belonged to a houſe for ſeveral deſcents. Theſe are never inventoried after the death of the owners as chattles; and therefore do not go to the executor or adminiſtrator, but to the heir along with the houſe, by cuſtom, and not by common law.

HALENIUM, ELECAMPANE, in botany, &c. is ranked by Linnæus among the ſtar-worts. See ELECAMPANE.

HELEPOLIS, in the ancient art of war, a machine for battering down the walls of a place beſieged, the invention of which is aſcribed to Demetrius, the Poliorcete.

Diodorus Siculus ſays, that each ſide of the helepolis was four hundred and five cubits broad, and ninety in height; that it had nine ſtages, and was carried on four ſtrong ſolid wheels eight cubits in diameter; that it was armed with large battering rams, and had two roofs capable of ſupporting them; that in the loweſt ſtages there were different ſorts of engines for caſting ſtones; and in the middle they had large catapultas for lancing arrows, and ſmaller in thoſe above, with a number of expert men for working all theſe machines.

HELIACAL, in aſtronomy, a term applied to the riſing or ſetting of the ſtars, or, more ſtrictly ſpeaking, to their emerſion out of and immerſion into the rays and ſuperior ſplendor of the ſun.

A ſtar is ſaid to riſe heliacally, when, after being in conjunction with the ſun, and ſo inviſible, it gets at ſuch a diſtance as to be ſeen before the ſun riſe; and it ſets heliacally, when it approaches ſo near the ſun as to be hid by his rays: ſo that ſtrictly theſe are only an apparition and occultation.

The heliacal riſing of the moon happens when ſhe is ſeventy degrees diſtant from the ſun; for the other planets twenty degrees diſtance is required; and for the ſtars more or leſs, according to their magnitude.

To find by the globe the time of the year when any known ſtar or planet will riſe or ſet heliacal: rectify the globe, and bring the ſtar or planet to the eaſt part of the horizon; then ſee what degree of the ecliptic is elevated above the weſtern horizon, according to the reſpective arch of viſion; then the oppoſite degree on the horizon, ſo found, compared with the calendar, will ſhew you the day of its riſing; and for its ſetting bring the ſtar or planet to the weſt-ſide of the horizon; obſerve to the eaſt what degree is elevated equal to the known arch of viſion; then, by the oppoſite degree, will be found the day of its ſetting.

HELIANTHEMUM, ſmall ſun-flower, in botany, is called by Linnæus ciſtus. See CISTUS.

HELIANTHUS, the great ſun-flower, in botany, a genus of plants, the compound flower of which is radiated, with a multitude of cylindraceous hermaphrodite flowers on the diſc, and a few very long ligulated female ones: the ſtamina are five filaments; and the ſeeds are ſingle, and contained in the cup. The flowers are yellow, and often more than a foot in diameter.

HELICE, in aſtronomy, the ſame with urſa major. See URSA.

HELICTERES, the ſcrew tree, in botany, a genus of plants, the flower of which conſiſts of five oblong petals, equal in breadth; and the fruit is compoſed of five unilocular capſules, containing a great many kidney-ſhaped ſeeds, and twiſted ſpirally about one another.

HELIOCENTRIC *Place of a Planet*, that place or point in the ecliptic wherein a planet would appear to a ſpectator placed in the center of the ſun.

The word is Greek, and compounded of ηλιος, the ſun, and κεντρον, a center.

The heliocentric place is the ſame with the longitude of a planet viewed from the ſun.

HELIOCENTRIC *Latitude of a Planet*, the latitude it would appear in at any time to a ſpectator placed in the ſun.

HELIOCOMETES, a phænomenon ſometimes obſerved about ſun-ſetting; being a large luminous tail, or column of light, proceeding from the body of the ſun, and dragging after it, not unlike the tail of a comet; whence the name.

HELIOSCOPE, in optics, a ſort of teleſcope, peculiarly adapted for obſerving the ſpots, eclipſes, &c. of the ſun.

The word is Greek, and compounded of ηλιος, the ſun, and σκοπεω, to view.

There are various apparatus's of this kind. Dr. Hook recommends four reflecting glaſſes placed in the tube, whereby the force of the rays will be ſo weakened, as only to ſtrike the eye with a 256th part of their force; and this he prefers to all others.

M. Huygens only blackens the inſide of the eye glaſs of the teleſcope, by holding it over the flame or ſmoke of a lamp, &c. or rather he blackens a piece of plain glaſs, and holds it between the eye and the object glaſs; or, which is beſt of all, he claps the ſmoked glaſs to another with a rim of thick paper between to keep the black from rubbing off, and fits the two into a frame, to be applied between the eye and the eye-glaſs. But the beſt method of viewing this luminary is by the ſolar teleſcope. See *Solar* TELESCOPE.

HELIOSTATA, in optics, an ingenious inſtrument invented by the learned Dr. s'Graveſande; ſo called from its uſe, which is to fix, as it were, the rays of the ſun in a horizontal direction a-croſs the dark chamber, all the while it is in uſe.

The word is formed from the Greek, ηλιος, the ſun, and ϛατιζω, to ſtop or fix.

This inſtrument is an automaton, or piece of clock-work, whoſe parts are as follows. A A (plate LXXIII, *fig.* 5.) is a frame, about which a metalline ſpeculum S is ſuſpended, moveable about its axis, by means of two ſmall ſcrews *a*, *a*. This frame is fixed to the piece C, which being hollow is moveable upon the cylindric ſhaft P. This pillar is fixed on a triangular baſe or foot ſet perpendicular, by the three ſcrews B, B, B.

On the back part of the ſpeculum is fixed a long cylindric wire, or tail D, in a perpendicular poſition. By this it is connected to the ſecond part of the helioſtata, which is a common thirty-four hour clock, repreſented at H; the plane of which clock is ſet parallel to that of the equator in any given place. This clock is ſuſtained on the column F G, in which it is moveable up and down by a thin lamina or plate that enters it as a caſe, and fixed to a proper height by two ſcrews *d*, *d*, at the ſide. The whole is truly adjuſted to a perpendicular ſituation by means of the three ſcrews I, I, I, in the tripod L, L, M, and the plummet Q, whoſe capſis muſt anſwer to the point *o* beneath.

The axis of the wheel which moves the index N O, over the hour circle, is ſomewhat large, and perforated with a cylindric cavity approaching a little to a conical figure; and receives the ſhank of the ſaid index N O very cloſe and tight, that by its motion the index may be carried round. In the extremity O of the index is a ſmall cylindric piece, with a cylindric perforation to receive the tail *t* of the fork T, yet ſo as to admit a free motion therein. In each ſide of the fork are ſeveral holes exactly oppoſite to each other, in which go the ſcrews *r*, *r*, upon whoſe ſmooth cylindric ends moves the tubular piece R.

When the machine is to be fixed for uſe, another part is made uſe of to adjuſt it; which is called the poſitor, and is denoted by the letters V X Y Z, *fig.* 6.

The cylinder C is removed with a ſpeculum from the foot P, and the braſs column V X put on in its ſtead, and adheres more ſtrictly to the pin *e*, that it may keep its poſition while the machine is conſtituted.

On the top of the column, about X as a center, moves the lever Y Z, ſo that it may be any how inclined to the horizon, and keep its poſition. The arm Y X may be of any length at pleaſure; but the arm X Z is of a peculiar conſtruction, and of a determinate length. To this arm, which extends no farther than *y*, is a ſliding-piece Z *x*, ſharp-pointed at Z. By this the arm X Z is determined to a given length, the piece Z *x* being fixed by the ſcrews *zz*. Upon this arm is drawn the ſhort line *v x*, by which it may be lengthened in the whole, and is $\frac{8}{100}$ of the whole length X Z, when ſhorteſt. The reaſon is, this arm is always to increaſe and decreaſe in proportion to the ſecant of the ſun's declination to the radius X Z, when ſhorteſt; but the radius is to the ſecant of 23° 30′, the ſun's greateſt declination, as 10000000 to 10904411, or as 100 to 109. Now the reaſon of this conſtruction of the arm X Z, is to find for any given day the diſtance of the center of the ſpeculum S from the top *l* of the ſtyle *l* N, which muſt ever be equal to the ſecant of the ſun's declination; for it muſt always be equal to the diſtance of the top of the ſaid ſtyle, *l*, from the center of the cylinder R in the fork T, and that is always equal to the ſaid ſecant of declination.

For ſince the ſtyle *l* N and the fork T are in a poſition parallel to each other, therefore the middle hole in the ſides of the fork being, as they muſt be, of the ſame height above the end of the index O, as is the height of the ſtyle N *l*, it is evident that on an equinoctial day the ſun's rays will paſs directly through the perforation of the piece R, if it be put in a poſition parallel to the plane of the ecliptic, or that of the clock; and alſo that the top of the ſhadow of the ſaid ſtyle will fall exactly on the ſaid hole.

In this caſe the top of the ſtyle is at the leaſt diſtance from the central point of R, and therefore may be repreſented by radius; while in any other poſition above or below, the diſtance will increaſe in proportion to the ſecant of the angle which the rays make with this firſt or middle ray, that paſs by the top of the ſtyle, and through the hole R.

Now it may be demonſtrated, that on any day of the

year, if the clock and its pedeſtal be ſo fixed that the line of XII be exactly in the meridian, and that the poſition of R in the fork be ſuch that the ſun's rays go directly through it, and the ſhadow of the ſtyle's top fall juſt upon the hole; moreover, if the diſtance of the center of the ſpeculum S from the top of the ſtyle *l* be made equal, by the poſitor, to the diſtance of the central point of R therefrom; and, laſtly, the tail of the ſpeculum D E paſſing through R; then if the clock be put into motion, the index N O ſhall carry about the tail of the ſpeculum, in ſuch a manner, that at all times of that day, when the ſun can come upon the ſpeculum, it will reflect the rays conſtantly in one and the ſame poſition and direction all the time without variation.

The machine thus conſtituted, is placed in a box or caſe, and ſet in a window with one ſide open, expoſed to the ſun, and all the other parts cloſe; ſo that when the room is made dark, and the ſolar microſcope fixed to the fore-part of the box in which the helioſtata is placed, juſt againſt the center of the ſpeculum to receive the reflected horizontal beam, all the experiments of the darkened room are then performed as uſual.

This is a very ingenious conſtruction of a ſolar microſcope-apparatus, but we fear too expenſive and troubleſome for common uſe. However, it is eaſy to ſee that this machine is capable of being greatly reduced; ſince it may be made to anſwer the end very well without a clock, and the ſpeculum may be glaſs inſtead of metal, and all fixed in one pedeſtal. See the article MICROSCOPE.

HELIOPTROPE, in natural hiſtory, a hard bluiſh-green jaſper, with red variegations. See the article JASPER.

HELIX, in geometry, the ſame with a ſpiral line.

The word is Greek, ἕλιξ, a wreath, or winding, and derived from εἱλεω, or ἑλισσω, to environ.

HELIX, in architecture. Some diſtinguiſh between it and ſpiral. Daviler ſays a ſtaircaſe is helical, when the ſteps wind round a cylindrical newel; whereas the ſpiral winds round a cone, continually approaching nearer its axis. Helix alſo denotes, in architecture, the caulicules or little volutes under the flower of the Corinthian capital, called likewiſe urillæ.

HELIX, in anatomy, the external circle or border of the ear, in contradiſtinction to the inner protuberance correſponding thereto, called the anthelix. See EAR.

HELL, *Gehenna*, *Tartara*, *Hades*, *Infernus*, &c. the place of divine puniſhment after death, in contradiſtinction to heaven. See the article HEAVEN.

As all religions have ſuppoſed a future ſtate of exiſtence after this life, ſo all have their hell or place of torment, in which the wicked are ſuppoſed to be puniſhed. The hell of the ancient heathens was divided into two manſions, the one called Elyſium, on the right hand, pleaſant and delightful, appointed for the ſouls of good men; the other called Tartara, on the left, a region of miſery and torment, appointed for the wicked. The latter was only hell in the preſent reſtrained ſenſe of the word. See the article ELYSIUM.

Of all the poets of antiquity, Virgil is the moſt particular in his deſcription of hell; having carried his hero thither, and given him a full view of theſe infernal regions: for an account of which we muſt refer the reader to the ſixth Æneid of that poet, where the many dreadful apparitions, as gorgons, harpies, chimæras, and the like, are ſtrongly painted, and a deſcription of Charon, the old ferryman of hell, his buſineſs, together with the office of Minos and Radamanthus, two of the judges of hell, are very lively repreſented. The opening of the adamantine gate diſcovers to Æneas the inmoſt receſſes of Tartara, or hell, which according to the poet is twice as deep as the earth is diſtant from the ſkies. Here Æneas ſees various perſons condemned to puniſhment, as alſo the different kinds and forms of torture, which are ſo numerous, that the poet concludes, *non mihi ſi linguæ centum*, &c.

"Had I an hundred mouths, an hundred tongues,
"And throats of braſs inſpir'd with iron lungs;
"I could not half theſe horrid crimes repeat,
"Nor half the puniſhments theſe crimes have met."
Dryden.

The philoſophers were of opinion, that the infernal regions were at an equal diſtance from all the parts of the earth; nevertheleſs it was the opinion of ſome, that there were certain paſſages which led thither, as the river Lethe, near the Syrtes, and the Acheruſian cave in Epirus. At Hermione it was thought, that there was a very ſhort way to hell; for which reaſon, the people of that country never put the fare into the mouths of the dead to pay their paſſage. Ulyſſes, according to Homer, went by ſea to the country of the Cimmerians, in order to go thither; and Æneas went by the lake of the cave of Avernus.

The Jews placed hell in the center of the earth, and believed it to be ſituated under waters and mountains. According to them there are three paſſages leading to it: the firſt is in the wilderneſs, and by that Korah, Dathan, and Abiram, deſcended into hell; the ſecond is in the ſea, becauſe Jonah, who was thrown into the ſea, cried to God out of the belly of hell; the third is in Jeruſalem, becauſe it is ſaid, "The fire of the Lord is in Zion, and his furnace is in Jeruſalem." They likewiſe acknowledged ſeven degrees of pain in hell, becauſe they find this place called by ſeven different names in Scripture. Though they believed that infidels, and perſons eminently wicked, will continue for ever in hell; yet they maintained, that every Jew who is not infected with ſome hereſy, and has not acted contrary to the points mentioned by the Rabbins, will not be puniſhed therein for any other crimes above a year at moſt.

The Mahometans believe the eternity of rewards and puniſhments in another life. In the Koran it is ſaid, that hell has ſeven gates, the firſt for the Muſſulmans, the ſecond for the Chriſtians, the third for the Jews, the fourth for the Sabians, the fifth for the Magians, the ſixth for the Pagans, and the ſeventh for the hypocrites of all religions.

Among Chriſtians, there are two controverted queſtions in regard to hell; the one concerns locality, the other the duration of its torments. The locality of hell, and the reality of its fire, began firſt to be controverted by Origen. That father interpreting the Scripture account metaphorically, makes hell to conſiſt not in external puniſhments, but in a conſciouſneſs or ſenſe of guilt, and a remembrance of paſt pleaſures.

Among the moderns, Mr. Whiſton advanced a new hypotheſis. According to him, the comets are ſo many bells appointed in their orbits alternately to carry the damned into the confines of the ſun, there to be ſcorched by its violent heat, and then to return with them beyond the orb of Saturn, there to ſtarve in theſe cold and diſmal regions. Another modern author, not ſatisfied with any hypotheſis hitherto advanced, aſſigns the ſun to be the local hell. As to the ſecond queſtion, viz. the duration of hell torments, we have Origen again at the head of thoſe who deny that they are eternal; it being that father's opinion, that not only men, but devils, after a due courſe of puniſhment ſuitable to their reſpective crimes, ſhall be pardoned and reſtored to heaven. The chief principle upon which Origen built his opinion, was the nature of puniſhment, which he took to be emendatory, applied only as phyſic for the recovery of a patient's health. The chief objection to the eternity of hell torments among modern writers, is the diſproportion between temporary crimes and eternal puniſhments. Thoſe who maintain the affirmative, ground their opinions on the Scripture accounts, which repreſent the pains of hell under the figure of a worm which never dies, and a fire which is not quenched; as alſo upon the words, "Theſe ſhall go away into everlaſting puniſhment, but "the righteous into life eternal."

HELLEBORE, *Helleborus*, in botany, a medicinal plant which the ancients reputed as a ſpecific for the cure of melancholy and madneſs, &c. There are two kinds of it, white and black hellebore.

White HELLEBORE, *Helleborus Albus*, ſneeze-wort, a plant with large oval ribbed leaves, crumpled and plaited as it were, ſet alternately on a round firm ſtalk, and embracing it by a tubulous baſis: in their boſoms, towards the top, appear cluſters of hexapetalous greeniſh-white flowers, followed each by three flat pods containing many triangular ſeeds: the root is ſhort and thick, with many

merous fibres hanging from it, externally of a brown colour, internally white. It is common on mountainous places in Germany, Switzerland, and ſome other parts of Europe.

White hellebore root has, when freſh, a diſagreeable ſmell; but as brought into the ſhops, ſcarcely any: its taſte is nauſeous, bitteriſh, acrid, very penetrating and durable. The juice of the freſh root, in taſte extremely acrid, is ſaid, when mixed with the blood, to act as a poiſon. The powder of the dry root is ſometimes mixed with external applications for deſtroying cutaneous inſects: ſnuffed up the noſe, in ſmall quantity, it proves a violent ſternutatory, and in this intention is ſometimes uſed in lethargic and other diſorders.

Black HELLEBORE, *Helleborus Niger*, or Chriſtmas-flower, a low plant, without any other ſtalk than the pedicles of the leaves and flowers, which are pretty thick, and generally ſtreaked with red or purple: the leaf is divided, quite to the pedicle, into ſix, ſeven, or more, ſmooth, firm ſegments, indented from about the middle to the extremity: the flower is large, naked, pentapetalous, of a pale roſe colour, with numerous ſtamina in the middle, which are followed by five or ſix pods full of ſhining blackiſh ſeeds, the petala continuing, and changing greeniſh: the root conſiſts of numerous fibres, hanging generally from a knotty head, externally of a black colour, internally white. It is perennial, grows wild in the mountainous parts of Germany; and flowers in our gardens in January.

Black hellebore root, in doſes of from ten grains to half a dram, proves a very ſtrong, though not very violent, cathartic. The hellebore of the ancients, which was never ventured on without extreme caution and as a laſt reſource, appears to have been a different ſpecies from ours, much larger and of more violent operation, called by Tournefort *helleborus niger orientalis, ampliſſimo, caule præalto, flore purpuraſcente*, which is ſtill ſaid to be found in plenty about Mount Olympus, and in the iſland of Anticyra, celebrated of old for the production of this reputed antimaniacal drug. In the preſent practice, this root or its preparations are uſed ſometimes as a purgative in hydropic and other caſes where the ſtronger cathartics are required, but oftener in ſmall doſes as an attenuant and deobſtruent. It is found particularly ſerviceable againſt obſtinate ſuppreſſions of the menſtrual purgations, in plethoric habits and ſanguine conſtitutions, where chalybeates are ineffectual or injurious.

The extract made with water is the beſt and ſafeſt preparation of this root when deſigned for a cathartic; as it contains both the purgative and diuretic parts of the hellebore, and as the irritating power of its active matter is conſiderably abated by the boiling: it may be given from eight or ten grains to a ſcruple or more, but is uſed oftener in conjunction with other materials of ſimilar intention than by itſelf. A tincture made in proof ſpirit appears the moſt eligible preparation for the purpoſes of an alterative or deobſtruent: four ounces of the root may be digeſted in a quart of the ſpirit, with the addition of thirty or forty grains of cochineal, to render the colour more ſightly; and the filtered tincture given to the quantity of a tea ſpoonful, twice a day, in warm water, or any other convenient vehicle.

HELLENISM, a ſort of Græciſm; a phraſe peculiarly adapted to the genius of the Greek tongue.

Helleniſm is diſtinguiſhed from Græciſm, in that the former is not applied to authors who have wrote in Greek, but to thoſe who, writing in ſome other language, uſe terms peculiar to the Greek.

HELLENISTIC, or HELLENISTIC LANGUAGE, that ſpoken among the Helleniſts.

The critics are divided as to their language. Several of them, among which are Druſius and Scaliger, take it to be the language uſed among the Græcian Jews: in this language the tranſlation of the Seventy was wrote, and the books of the New Teſtament compoſed: it was only thus denominated to ſhew that it was Greek mixed with Hebraiſms and Syriaciſms.

HELM, in the marine, an engine of wood hung on the outſide of a ſhip behind, upon certain googings bolted to the ſtern-poſt, upon which it revolves, and by its motion directs the courſe of the ſhip at ſea.

The helm is compoſed of two or three parts, viz. the rudder, the tiller, and the wheel; this laſt part however is ſeldom uſed but in men of war, and the largeſt merchant-ſhips.

The rudder is that part of the helm which is hung on the outſide of the ſtern-poſt, as before deſcribed: in the top of the rudder there is a mortice cut, into which is firmly bolted the tiller, which is a piece of timber thruſt into the rudder to turn it; and, laſtly, the wheel is employed to move the tiller with greater facility from one ſide to the other, in directing the ſhip.

HELMET, an ancient defenſive armour worn by horſemen, both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front ſecured by bars, which was called the viſor.

It is ſtill uſed in heraldry by way of creſt over the ſhield or coat of arms, in order to expreſs the different degrees of nobility, by the different manner in which it is borne. Thus a helmet in profile is given to gentlemen and eſquires: to a knight, the helmet ſtanding forward, and the beaver a little open: the helmet in profile and open, with bars, belongs to all noblemen under the degree of a duke: and the helmet forward and open, with many bars, is aſſigned to kings, princes, and dukes.

HELVE, a term uſed among country people for the handle of a hatchet, pick-ax, mattock, or the like.

HELXINE, buck-wheat. See the article BUCK-WHEAT.

HEMERODROMI, in Grecian antiquity, centinels and guards appointed for the ſecurity and preſervation of cities and other places.

HEMICRANIA, in medicine, a ſpecies of head-ach, wherein only one half or ſide of the head is affected. See HEAD-ACH.

HEMICYCLE, in architecture, is defined by Daviler to be an arch forming a perfect ſemicircle. See the articles ARCH and BRIDGE.

To conſtruct ſuch an arch of hewn ſtone, they divide hemicycle into a certain number of equal parts, and faſhion an equal number of vouſoirs, which will complete the arch: however, that there may be no joint in the middle, where the key-ſtone ſhould be, they always take care that the number of vouſoirs be an odd one.

HEMICYCLIUM, in antiquity, a part of the orcheſtra in the ancient theatres.

HEMICYCLIUM alſo ſignified a kind of ſun-dial; being a concave ſemicircle, the upper cuſp of which looked to the north. On the middle of the hemicyclium ſtood a ſtyle, whereof the point that correſponded to the center of the hemicycle, repreſented the center of the earth; and its ſhadow, being projected on the concavity of the hemicycle, which repreſented the ſpace between the two tropics, pointed out not only the declination of the ſun, and the day of the month, but likewiſe the hour of the day.

HEMINA, in Roman antiquity, a liquid meaſure which, according to Arbuthnot, was equal to half a wine-pint Engliſh meaſure; its contents being 2,818 ſolid inches. See the article MEASURE.

HEMISPHERE, *Hæmiſpherium*, in geometry, the half of a globe or ſphere, when divided into two by a plane paſſing through its center.

The word is Greek, and compounded of *ημισυς*, half, and *σφαιρα*, a ſphere.

The center of gravity of a hemiſphere is $\frac{5}{8}$ of the radius diſtant from the vertex. It is proved in optics, that a glaſs hemiſphere unites the parallel rays at the diſtance of a diameter and one third of a diameter from the pole of a glaſs.

HEMISPHERE, in aſtronomy, particularly denotes one half of the mundane ſphere. The equator divides the ſphere into two equal parts, called the northern and ſouthern hemiſpheres, having the north and ſouth poles in their reſpective zeniths. The horizon alſo divides the ſphere into two hemiſpheres, the upper and lower, having the zenith and nadir in their reſpective vertices.

HEMISPHERE alſo denotes a projection of half the terreſtrial globe or half the celeſtial ſphere on a plane, and is frequently called planiſphere.

HEMISPHEROIDAL, in geometry, an appellation given

given to whatever approaches to the figure of an hemiſphere, but is not exactly ſo.

HEMISTICH, ημιστιχον, in poetry, denotes half a verſe, or a verſe not completed.

Of this there are frequent examples in Virgil's Æneid; but whether they were left unfiniſhed by deſign or not, is diſputed among the learned: ſuch are, *Ferro accincta vocat*, Æ. II. v 614. And, *Italiam non ſponte ſequor*, Æ. IV. v. 361.

In reading common Engliſh verſes, a ſhort pauſe is required at the end of each hemiſtich, or half verſe.

HEMITONE, in the ancient muſic, what we now call a half note or ſemitone.

HEMITRITÆUS, in medicine, a kind of fever denoting the ſame as ſemi-tertian, returning twice every day.

The word is Greek, and compounded of ημισυς, half, and τριταιος, third or tertian.

HEMLOCK. See CICUTA.

HEMP, *Cannabis*, in botany, a very uſeful plant for making cordage and all things of that kind.

The ſtalks of hemp grow to be five or ſix feet high, angular, and covered with a ſtrong tough bark; and cloathed with many digitated leaves, each compoſed of five, ſix, or ſeven parts, long and narrow, ſharp pointed and ſerrated about the edges, the middlemoſt being longeſt, ſet together upon one foot-ſtalk; they are green above and hoary underneath, and rough in handling. The flowers, in that they call the male, grow towards the top of the ſtalk in bunches, ſmall and ſtaminous, which periſh without bringing any ſeed, which is produced by the female without any previous flowers.

Hemp is a uſeful plant, purchaſed at a dear rate from foreigners, when it might be cultivated among ourſelves, to the great benefit of the nation in general. It delights in warm, ſandy, or ſomewhat gravelly ſoil; but it muſt be ſomewhat rich, and of a good depth. The beſt ſeed is that which is brighteſt, and retains its colour and ſubſtance in rubbing. Three buſhels will ſow an acre; but the richer the land is, the thicker it muſt be ſown, and the poorer it is, the thinner. The time of ſowing it, is from the latter end of March, to the end of April, according as the ſpring falls out; but the earlier it is ſown the better. If it be a dry ſeaſon, great care muſt be taken to preſerve it from birds.

The firſt ſeaſon for gathering it is about Lammas, when a good part of it will be ripe; that is, the light ſummer hemp which bears no ſeed, and is called fimble-hemp. When it is ripe the ſtalks grow white, and the leaves fall downwards, turning yellow at the top; it muſt then be pulled up, dried, bound up in bundles as big as may be graſped in both hands, and laid by for uſe. Care muſt be taken not to break what is left ſtanding, becauſe it is to grow till near Michaelmas before it will be fit to gather: this is uſually called karle-hemp. When it is gathered, lay it in the ſun three or four days to dry, and then ſtack or houſe it till the ſeed be threſhed out.

An acre of hemp, in the beſt land, commonly yields about two or three quarters of ſeed, which, with the hemp unwrought, is often worth from 5 to 8 l. but if wrought, from 10 to 12 l. but the fimble-hemp is not worth above half as much as the other.

As to the method of preparing it, after the ſeeds are threſhed out of the heads, and the ſtalks are laid up in bundles and ſteeped in a ſtanding water, the cleaner it is the better; they are faſtened to poles, and left to ſoak about fifteen days; and when the ſubſtance of the ſtalk is almoſt rotten, the bundles are taken out and well dried. But flax, inſtead of being ſteeped in water, is uſually expoſed alternately to the moiſt air of the night, and the heat of the ſun, by which means it receives a finer colour.

When hemp and flax are well penetrated and afterwards completely dried, they are bruiſed by handfuls on a block, with a kind of mallet; all the bullen, which is the inward ſubſtance of the ſtem, flies off in ſhivers, by the force of the blows, and nothing remains in the hands of the beater but the thin bark in large threads, through the whole length of the ſtem. This parcel of threads is afterwards hung on a perpendicular board, and bruiſed with a wooden beetle, in order to ſhake out all the little ſtraws that may happen to remain of the bullen. All the groſs parts are now ſeparated from the ſtem, and the threads of the bark receive their perfection from the comb or hatchel. See HATCHEL.

The refuſe of this combing, which conſiſts of all the threads which are too thick, is called tow, for the uſe of which ſee the article TOW.

Hemp and flax are the materials of a variety of profitable manufactures; for beſides linnen, great quantities of ticken of all fineneſſes, ſail-cloth, incle, tape, ſacking, girtwip, cordage, twine, nets, and many other things are made of them: and they furniſh multitudes of other manufactures, which employ the poor, and bring, by their exports, profit to the nation. But as we are under the neceſſity of importing very large quantities of hemp from foreign countries, the production of this article among ourſelves, and in our plantations, cannot be too plentifully cultivated, nor too highly encouraged.

For the laws relating to hemp and flax, ſee the article FLAX.

HEN, *Gallina*, in ornithology, though uſed in a general ſenſe to ſignify any female bird, is more particularly reſtrained to thoſe of the order of gallinæ.

HEN-BANE, a plant called by botaniſts hyoſciamus. See HYOSCIAMUS.

HEN-MOULD, among farmers, denotes a black ſpungy ſoil, fitter for grazing than for corn.

In ſome places, indeed, they give the name of hen-mould to a rich black earth mixed with whitiſh ſtreaks, which is exceeding fertile.

HENOTICON, in church-hiſtory, a decree or edict of the emperor Zeno, made at Conſtantinople, in the year 482, by which he pretended to reconcile all parties under one faith. It is generally agreed that Peter, patriarch of Alexandria, and Acacius, patriarch of Conſtantinople, were the authors of this decree, and that their deſign was to compliment the emperor with a right of preſcribing regulations in matters of faith. The emperor, by this decree, arrogated to himſelf the right of being head of the church. Pope Simplicius, however, in the year 483, condemned the henoticon, and cited Acacius, the chief promoter of it, to appear before him at Rome; but it was not entirely ſuppreſſed till the year 518.

HENTING, among farmers, a method of ſowing immediately before the plough, by which, it is pretended, a great deal of charge is ſaved. See PLOWING.

HENTING-FURROWS, thoſe turned from each other at the bottom, in plowing ridges. See the article PLOWING.

HEPAR, the liver, in anatomy. See LIVER.

HEPATIC, in medicine and anatomy, any thing belonging to the liver.

HEPATIC ALOES. See ALOES.

HEPATIC VEIN. See BASILICA.

HEPATICA, noble liverwort, in botany, a low plant without any other ſtalk than the pedicles of the leaves and flowers; the leaf is cut, not very deep, into three lobes, entire about the edges; the flower is commonly blue, ſometimes reddiſh or white, hexapetalous, ſet in a three-leaved cup, with numerous ſtamina in the middle, which are followed by a cluſter of whitiſh ſeeds. It is perennial, grows wild on gravelly ſhady grounds in Germany and other parts of Europe, and flowers in our gardens in March or ſooner.

This herb is a mild reſtringent and corroborant; to which intentions, infuſions of it have been drank as tea, or the powder of the dry leaves given to the quantity of half a ſpoonful at a time.

HEPATICA, liverwort, in botany, a ſpecies of moſs conſiſting of numerous obtuſely laciniated leaves, lying over one another, marked on the ſurface with white tubercles reticularly diſpoſed through the green ſubſtance of the leaf, ſhooting out underneath fine capillary roots from the extremities of the leaves iſſue clear whitiſh pedicles, bearing globular bodies, which when ripe contain black minute ſeeds like duſt. It is perennial, grows in moiſt ſtony places, and runs up to ſeed in March or April.

This moſs is recommended as an aperient, reſolvent and purifier of the blood. From the penetrating but mild pungency and bitteriſhneſs of its taſte, ſinking in

were into the tongue, it promiſes to be a plant of no inconſiderable virtue, though in this country at preſent diſregarded.

HEPATITIS, in medicine, an inflammation of the liver, with an impoſthume of that organ. It bears a near reſemblance to the pleuriſy, only its ſymptoms are not ſo intenſe. It commonly either kills the patient or ſuppurates gradually, or degenerates into a ſchirrhus. See LIVER.

HEPHÆSTIA, in Grecian antiquity, an Athenian feſtival in honour of Vulcan, the chief ceremony of which was a race with torches.

HEPTACHORD, in the ancient poetry, ſignified verſes that were ſung or played on ſeven chords, that is, on ſeven different notes. In this ſenſe it was applied to the lyre, when it had but ſeven ſtrings.

One of the intervals is alſo called an heptachord, as containing the ſame number of degrees between the extremes.

HEPTAGON, in geometry, a figure conſiſting of ſeven ſides and as many angles.

The word is Greek, and compounded of ἑπτα, ſeven, and γωνια, an angle.

If the ſides be all equal, it is called a regular heptagon.

HEPTAGONAL NUMBERS, are a ſort of polygonal numbers, wherein the difference of the terms of the correſponding arithmetical progreſſion is 5.

One of the properties of theſe numbers is, that, if they be multiplied by 40, and 9 be added to the product, the ſum is a ſquare number.

HEPTAMERIS, in muſic, the ſeventh part of a meris, being, according to M. Sauveur, the forty-third part of the octave. See the article OCTAVE.

HEPTANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and ſeven male parts or ſtamina in each.

The word is formed of the Greek ἑπτα, ſeven, and ανηρ, male.

Of this claſs are the horſe-cheſnut, finitelis, &c.

HEPTANGULAR, in geometry, an appellation given to figures which have ſeven angles.

HEPTARCHY, a government conſiſting of ſeven perſons, or a country divided into ſeven kingdoms.

The word is Greek, and formed of ἑπτα, ſeven, and αρχη, rule.

The Saxon heptarchy included the ſouthern and northern parts of England, which was cantoned into ſeven petty kingdoms, as thoſe of Kent, South-Saxons, Weſt-Saxons, Eaſt-Saxons, Northumberland, the Eaſt-Angles, and Mercia. The heptarchy was formed by degrees from the year 457, when the kingdom of Kent was firſt erected, and terminated in 805, when king Egbert re-united them into a monarchy.

HEPTATEUCH, in literature, a volume conſiſting of ſeven books.

The work is Greek, and compounded of ἑπτα, ſeven, and τευχος, a book or work.

Heptateuch chiefly denotes the five books of Moſes called the Pentateuch, together with the two following books, Joſhua and Judges.

HERACLEIA, an ancient feſtival, celebrated in honour of Hercules by ſeveral ſtates of Greece.

HERACLEONITES, a ſect of Chriſtians, the followers of Heracleon, who refined upon the Gnoſtic divinity, and maintained that the world was not the immediate production of the Son of God, but that he was only the occaſional cauſe of its being created by the Demiurgus. The Heracleonites denied the authority of the prophecies of the Old Teſtament, maintaining that they were mere random ſounds in the air; and that St. John the Baptiſt was the only true voice that directed to the Meſſiah.

HERACLIDÆ, or *Return of the* HERACLIDÆ *into Peloponneſus*, in chronology, a famous epocha that conſtitutes the beginning of profane hiſtory; all the time preceding that period being accounted fabulous.

This return happened in the year of the world 2862, an hundred years after they were expelled, and eighty after the deſtruction of Troy.

HERAIA, an ancient Greek feſtival obſerved at Argos and ſome other places, in honour of Juno.

This name was alſo given to a ſolemn day of mourning kept at Corinth for Medea's children, who were buried in the temple of Juno Aſtræa.

HERALD, an officer at arms, whoſe buſineſs it is to declare war, to proclaim peace, to marſhal all the ſolemnities at the coronation, chriſtening, marriage, and funeral of princes, to blazon and examine coats of arms, &c.

Heralds were formerly held in much greater eſteem than they are at preſent, and were created and chriſtened by the king, who pouring a gold-cup of wine on their head, gave them the herald-name; but this is now done by the earl-marſhal. They could not arrive at the dignity of herald without having been ſeven years purſuivant; nor could they quit the office of herald, but to be made king at arms. See POURSUIVANT.

The three chief heralds are called Kings at Arms, the principal of which is Garter; the next is called Clarencieux, and the third Norroy; theſe two laſt are called provincial heralds. See KING *at Arms*.

Beſides theſe there are ſix other inferior heralds, viz. York, Lancaſter, Somerſet, Richmond, Cheſter, and Windſor; to which, on the coming of king Geo. I. to the crown, a new herald was added, ſtyled Hanover herald; and another, ſtyled Gloceſter king at arms.

The kings at arms, the heralds, and four purſuivants are a college or corporation, erected by a charter granted by Richard III. by which they obtained ſeveral privileges, as to be free from ſubſidies, tolls, and all troubleſome offices.

HERALDRY, the art of armoury and blazoning, which comprehends the knowledge of what relates to ſolemn cavalcades and ceremonies at coronations, inſtalments, the creation of peers, nuptials, funerals, &c. and alſo whatever relates to the bearing of arms, aſſigning thoſe that belong to all perſons, regulating their right and precedencies in point of honour, and reſtraining thoſe who have not a juſt claim, from bearing coats of arms that do not belong to them. See BLAZONING, ARMS, SHIELD, BEARING, &c.

HERB, a denomination common to all plants, whoſe ſtalks die every year, after their ſeed is ripe.

The word is derived from the Latin *herba*, which ſignifies the ſame thing.

There are ſome herbs whoſe root periſhes with the ſtem, and others where the root ſurvives the ſtem by ſeveral years. The former are called annuals: thoſe which only bear flowers and fruit the ſecond year, or even the third, and then periſh, are called biſannuals. Herbs whoſe roots do not periſh after they have ſhed their ſeed, are called perennials, and, if they keep their leaves all the year round, they are called ever-greens. Herbs are alſo diſtinguiſhed into kitchen, ſallad, and medicinal herbs.

HERBAGE, in law, ſignifies the paſture provided by nature for the food of cattle; alſo the liberty to feed cattle in the foreſt, or in another perſon's ground.

HERBAL, in literary hiſtory, a book that treats of the claſſes, genera, ſpecies, and virtues of plants.

HERBAL is ſometimes alſo uſed for what is more uſually called hortus ſiccus.

HERBALIST, the author of an herbal, or one who is ſkilled in plants.

HERBIVOROUS ANIMALS, thoſe which feed only on vegetables.

HERCULES, in aſtronomy, one of the conſtellations of the northern hemiſphere. See the article CONSTELLATION.

HERD, a company of eatable cattle of the larger ſort, as cows, oxen, ſwine, deer, &c. alſo of wild beaſts.

HEREDITAMENTS, whatever immoveable things a perſon may have to himſelf and his heirs, by way of inheritance; and which, if not otherwiſe bequeathed, deſcend to him who is next heir, and not to the executor, as chattels do.

This word extends to whatever is inheritable, be it real, perſonal, or mixed; and in conveyances, by the grant of hereditaments, manors, houſes, lands, rents, &c. will paſs.

HEREDITARY, an appellation given to whatever

belongs to a family by right of ſucceſſion, from heir to heir.

HERESY, the crime of obſtinately perſiſting in opinions that are contrary to the fundamentals of religion.

HERETIC, a general name for all ſuch perſons under any religion, but eſpecially the Chriſtian, as profeſs or teach religious opinions contrary to the eſtabliſhed faith, or to what is made the ſtandard of orthodoxy.

HERISSON, in fortification, a beam armed with a great number of iron ſpikes, with their points outwards, and ſupported by a pivot, on which it turns.

Theſe ſerve as a barrier to block up any paſſage, and are frequently placed before the gates, and more eſpecially the wicket-doors of a town or fortreſs, to ſecure thoſe paſſages, which muſt of neceſſity be often opened and ſhut.

HERMÆ, among antiquarians, ſtatues of the god Mercury, made of marble, and ſometimes of braſs, without arms or feet, and ſet up by the Greeks and Romans in the croſs-ways.

HERMÆA, in antiquity, ancient Greek feſtivals, in honour of the god Hermes, or Mercury.

HERMAPHRODITE, one who partakes of both ſexes.

The word is Greek, Ερμαφροδιτος, and compounded of Ερμης, Mercury, and Αφροδιτη, Venus, as being a mixture of Mercury and Venus, that is, of male and female.

Moſt, if not all thoſe reported to be hermaphrodites, are probably no other than mere women, whoſe clitoris is grown to an exorbitant ſize, and whoſe labia pudendorum are become preternaturally tumid.

Among the inſect claſs of animals, indeed, hermaphrodites are very frequent: ſuch are worms, ſnails, leeches, &c.

HERMAPHRODITE FLOWERS, among botaniſts. See FLOWER.

HERMATHENA, among antiquarians, a ſtatue repreſenting Mercury and Minerva both in one.

HERMETIC, or HERMETICAL, an appellation given to whatever belongs to chemiſtry, from Hermes Triſmegiſtus, who is ſuppoſed to have been its inventor.

HERMETICAL PHILOSOPHY, that which undertakes to ſolve all the phænomena of nature from the three chemical principles, ſalt, ſulphur, and mercury. A conſiderable addition was made to the ancient hermetical philoſophy by the modern doctrine of alkali and acid. See ALKALI.

HERMETICAL PHYSIC, the art of healing as founded on the hermetical philoſophy.

HERMETICAL SEAL, a method of ſtopping glaſs-veſſels for chemical operations ſo very accurately, that nothing can eſcape. It is done by heating the neck of the veſſel in the flame of a lamp, till it be ready to melt, and then twiſting it cloſe together with a pair of pincers.

Veſſels may likewiſe be ſealed hermetically, by ſtopping them with a plug of glaſs well luted into the neck of the veſſel; or by inverting another ovum philoſophicum over that wherein the matter is contained.

HERMIT, a devout perſon retired into ſolitude to be more at leiſure for prayer and contemplation.

The word is derived from the Greek, ερημος, a wilderneſs.

HERMODACTYL, in pharmacy, the root of an unknown plant, brought from Turky; of the ſhape of a heart flatted; of a white colour; compact and ſolid, yet eaſy to cut or powder.

This root has a viſcous, ſweetiſh, farinaceous taſte, and no remarkable ſmell. It was ranked by the ancients among the cathartics, but ſuch as we now meet with in the ſhops does not appear to have any purgative virtue. Alpinus relates, that hermodactyls, the ſame with what are ſold in Europe, are eaten by the Egyptian women, to the quantity of ſeveral roots at a time: that they do not move the belly, or produce any ill effect: that they are ſuppoſed to be very nutritious, and contribute to procure the fatneſs and plumpneſs there admired. Thoſe who report them to be a purgative, have probably aſcribed to the hermodactyls, a part of the effects of the ſubſtances which were joined to them; for, being acknowledged ſlow in operation, they have been commonly acuated with aloes and other cathartics; and have long been an entire ſtranger to practice.

HERNANDIA, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: the petals of the flower are multifid, and placed in a circular order; the male and female flowers ſtand on diſtinct plants. There is no pericarpium, but the cup of the flower is very large, ſwelled, and roundiſh; containing a plicated oval nut, with only one cell, and a globoſe nucleus. *Linnæi Gen. Plant.*

We know only one ſpecies of this genus, which is the hernandia, with a large umbilicated ivy-like leaf, commonly called, in the Weſt-Indies, Jack in a box.

HERNIA, in medicine, a tumor formed by the deſcent of the inteſtines or omentum out of their place: it is popularly called a rupture.

The word is Latin, and originally ſignifies a tumor in the ſcrotum.

The preternatural tumors formed at the navel are called omphalocele and exomphalos; thoſe of the ſcrotum oſcheocele; and if in other parts of the belly, they are called ventral. A tumor proceeding from a falling out of the inteſtines, is termed an enterocele; from the omentum, epiplocele; from wind, pneumatocele; from water, hydrocele. They differ alſo as to their ſize; ſome are ſoft, others hard; ſome fixed, ſome moveable, others not without great difficulty, or not at all returned into the abdomen; the laſt are called adheſive ruptures. Sometimes the parts prolapſed are ſo confined, that the wind and fæces can by no means be tranſmitted; theſe are denominated incarcerated ruptures; ſome are free from pain; others very painful, and attended with ſickneſs, vomiting, and many bad ſymptoms.

The cauſes are various, though the immediate cauſe is always ſome violence offered to the abdomen, and principally the navel.

An omphalocele in children is not very dangerous, and for the moſt part eaſily cured. In adults likewiſe there is no great danger, while the parts are capable of being returned; but if the protruſion of the inteſtines through a narrow foramen of the navel cannot be returned, it is a very hazardous caſe; for the blood muſt be prevented from returning out of the protruded inteſtines, and the ſtagnating fluids occaſion inflammation, exceſſive pain and anguiſh, with vomiting, and indeed the iliac paſſion; and likewiſe a mortification of the inteſtines, followed by a painful death. But if the inteſtines can be returned, an omphalocele, as well as any other rupture, is ſooner cured in children than in adults, by the uſe of a proper bandage, and the obſervation of a regular diet and exerciſe.

There are two methods of cure, the one when the inteſtines can, the other, when they cannot be returned. In the firſt caſe, the inteſtines and omentum muſt be returned and bound up tightly to prevent a relapſe. In tender infants, after repreſſion and repoſition, apply a ſmall round plaſter to the navel, laying another over that covered with linen or leather, and over this a ſimple thick compreſs, as in a recent and ſlight diſorder; then faſten the whole with a ſimple roller carried ſeveral times round the body, taking care, when this is opened, that it be immediately bound up.

When the diſorder is inveterate, uſe a double compreſs of a leſs ſize, and upon that lay a leaden plate, then a larger compreſs, and proceed as before: but in children, adults, and old men, apply a truſs ſuitable to the purpoſe, furniſhed with a peculiar plate, and faſtened round the belly; but before you uſe this bandage, you ſhould lay on the navel a ſound ſtrengthening plaſter, and upon that a ſticking plaſter with a compreſs: but if the aperture is ſo narrow that the inteſtines cannot be repelled, and the patient is troubled with a vomiting and acute pains, apply proper clyſters and emollient cataplaſms. If you ſtill find the inteſtines unfit for repoſition, inject the ſmoke of tobacco into the anus, till it give a ſtool, and they are relaxed. If there is an inflammation in the inteſtines, you muſt immediately open a vein, and bleed plentifully; by this, with a gentle preſſure of the hand, the prolapſed parts return into the abdomen: after this, you muſt preſs the

the orifice with your fingers, apply a compreſs, and then a proper linen bandage as before.

If all this prove ineffectual in twenty or twenty-four hours, immediate recourſe muſt be had to the chirurgical operation, which is thus performed: the patient is laid on a bed or table, with his head ſomewhat low, but his belly and buttocks elevated, and is faſtened down to prevent his moving; then the ſkin over the navel is held tranſverſely, and, being drawn tight, an inciſion is carefully made with a knife, till you have uncovered the inteſtines. The beſt inſtrument for this inciſion is Morand's biſtouri gaſtrorapbique, or le Dran's biſtouri herniaire.

Where the inteſtines are thus replaced, the wound, being preſſed by an aſſiſtant, ſhould be bound up. After the firſt dreſſing, the patient muſt keep quiet, and the bandage remain for three or four days, unleſs extraordinary ſymptoms require the contrary; and after the firſt opening, it may be dreſſed every day; and when it is healed, a proper bandage is ſtill neceſſary, but adults and old men muſt wear a truſs all their lives. As to Petit's method of cure, ſee *Garangeot's Operat. Chirurg.*

For the cure of an enterocele without inciſion, one Littlejohn uſed the following method: firſt, he returned the inteſtines into the belly, then applied a corroſive medicine above the os pubis, to the place where the inteſtines deſcended; and he recommends oil of vitriol, in ſuch plenty, that it might ſoon penetrate the ſkin; for the deeper the eſchar, the more effectual the remedy: therefore he orders it to be repeated for three or four days, that the ſkin may be more corroded; and upon every freſh application of the oil, he removed the old eſchar; then he dreſſed the wound with a plaſter of paracelſus and oxycroceum, mixed in equal parts, and ſpread upon leather, and ſecured it with compreſſes and bandage. This plaſter alone, he affirms, ſeparates the eſchar, and cures the ulcer. He ordered any excreſcence of ſpongy fleſh to be eaten off with the lapis infernalis. The patient muſt obſerve a ſpare diet, and refrain from exerciſe till the wound be cured: after which, he lays the rupture plaſter on the cicatrix, and applies a proper bandage, which muſt be worn till the cicatrix be ſtrong enough to prevent a relapſe. King George I. gave five thouſand pounds for this arcanum, which was ſoon after deſpiſed by the Engliſh.

The celebrated method of the prior de Cabrier for curing an enterocele, or any rupture, without bandage or ſection, though it does not prove effectual without containing the former, was purchaſed about the end of the laſt century by Lewis XIV. and then made public for the good of mankind. It is done by ſpirit of ſalt mixed with red wine, and drank for ſeven mornings faſting, the patient remaining for four or ſix hours afterwards without taking either food or drink: but if it ſhould not agree with the ſtomach, then only every other day. For a child, from two years old to ſix, three or four drops in a ſpoonful or two of red wine; from ſix years to ten, mix a dram of the ſpirit with a pint of wine for ſeven doſes. It is to be continued, if neceſſary, for a fortnight longer in the ſame manner. From ten to fourteen years, the quantity of the ſpirit may be increaſed to two drams: from fourteen to eighteen, two drams and a half; and after eighteen, five drams. During four months, after this courſe is begun, a ſteel truſs muſt be worn night and day, exactly fitted to the rupture.

The patient ought never to ſit down, but either ſtand or lie, and neither run nor ride, and take great care to commit no error in diet. Under the truſs the following plaſter is applied to the part, being firſt ſhaved. Take of maſtich half an ounce; labdanum, three drams; hypocyſtis, one dram; three dried Cyprus nuts; of ſealed earth, one dram; black pitch, three ounces; Venice turpentine, one dram; yellow wax, one ounce; dry comfrey-root, half an ounce; make into a plaſter according to art.

HERO, in the ancient mythology, a great and illuſtrious perſon, of a mortal nature, though ſuppoſed by the populace to partake of immortality; and, after his death, placed among the number of the gods.

Heroes were perſons partly of divine and partly of human extraction, being begot between a deity and a mortal, and coincides with what we otherwiſe call a demi-god; ſuch was Hercules, who was the ſon of Jupiter by Alcmena: accordingly Lucian deſcribes a hero to be a medium between a god and man, or rather a compoſition of both.

HERO is alſo uſed in a more extenſive ſenſe for a great, illuſtrious, and extraordinary perſonage; particularly in reſpect of valour, courage, intrepidity, and other military virtues.

F. Bouhours makes this diſtinction between a hero and a great man, that the former is more daring, fierce, and enterprizing; and the latter more prudent, thoughtful, and reſerved. In this ſenſe we ſay, Alexander was a hero, and Julius Cæſar a great man.

HERO *of a Poem, or Romance*, is the principal perſonage, or character therein. See the article CHARACTER.

The hero of the Iliad is Achilles; of the Odyſſee, Ulyſſes; of the Æneid, Æneas; of Taſſo's Jeruſalem, Godfrey of Bulloign; of Milton's Paradiſe Loſt, Adam; though Mr. Dryden will have the Devil to be Milton's hero, in regard he gets the better of Adam, and drives him out of Paradiſe.

Many of the critics find fault with the hero of the Æneid, for being too delicate, wanting the fire, firmneſs, and uncontroulable ſpirit, remarkable in the hero of the Iliad. Piety, tenderneſs, and ſubmiſſion to the gods, are virtues of the middle claſs of mankind; they do not ſtrike enough for a hero who is to be the inſtrument of ſuch notable exploits. In anſwer to this, F. Boſſu obſerves, that Æneas's character was not to be formed on the model either of Achilles or Ulyſſes; nor to be of the ſame kind with them, as the fable and deſign of the Æneid were very different from thoſe of the Iliad and Odyſſee. Virgil's deſign was to perſuade the Romans to receive a new form of government, and a new maſter; who muſt have all the qualities requiſite for the founder of a ſtate, and all the virtues which make a prince beloved.

HEROIC, ſomething belonging to a hero, or heroine: thus,

HEROIC AGE, that age or period of the world wherein the heroes are ſuppoſed to have lived. The heroic age coincides with the epic poem. See EPIC.

HEROIC VERSE, that wherein heroic poems are uſually compoſed; or it is that proper for ſuch poems. In the Greek and Latin, hexameter verſes are uſually denominated heroic verſes, as being alone uſed by Homer, Virgil, &c. See the article HEXAMETER.

Alexandrine verſes of twelve ſyllables were formerly called heroic verſes; but later writers uſe verſes of ten ſyllables.

HEROINE, a woman of an heroic ſpirit, or who makes the principal perſonage in an heroic poem. See HERO and POEM.

HERON, in ornithology, a bird of the ardea-kind, with a hanging creſt.

The common heron is a tall bird, meaſuring more than four feet from the point of the beak to the tip of the toes. Its head is covered with ſhort white feathers; only from the hinder part, there hangs a creſt of very long black feathers; the upper part of its body is of a duſky bluiſh grey, the under part white, and the thighs yellowiſh.

HERPES, in medicine, a bilious puſtule, which breaking out in different manners upon the ſkin, accordingly receives different denominations.

If they appear ſingle, as they frequently do in the face, the baſe is inflamed, and the top pointed; and having diſcharged a drop of matter, the redneſs and pain go off, and they dry away. There is another ſort more corroſive and of greater malignity, when a cluſter of puſtules riſe in a ring, accompanied with ſmart, and ſometimes with great itching; this ſpecies is termed ſerpigo, and vulgarly the tetter, or ring-worm.

Another kind of this diſeaſe appears in large cluſters upon the neck, breaſt, loins, &c. attended with a ſlight fever and inflammation. The heads are white and mattery, which are ſucceeded by a ſmall round ſcab reſembling millet ſeed, whence its name, and vulgarly called ſhingles. See the article ERYSIPELAS.

HERRING, in ichthyology, a ſpecies of clupea, with

the lower jaw longeſt, and without any black ſpots. It is from five to eight inches in length, and between one and two in breadth. However, its ſize is far from being certain; ſince it varies not only on account of age, but according to the ſeas and places where it is caught. The back is of a duſky bluiſh colour, and is more blue in ſpring than at other times; the ſides and the belly are of a ſilvery white; the fin on the back ſtands near the middle, and is of a whitiſh colour, and has nineteen rays; the pectoral fins are whitiſh, ſtand low, and have each eighteen rays; the ventral fins are very ſmall and white; the pinna ani is near the tail, and has eighteen rays; the tail is of a greyiſh colour, forked, and furniſhed with eighteen rays.

HERRING *Fiſhery*. Herrings are chiefly found in the North ſea. They are a fiſh of paſſage, and commonly go in ſhoals, being very fond of following fire or light, and in their paſſage they reſemble a kind of lightning. About the beginning of June, an incredible ſhoal of herrings, probably much larger than the land of Great-Britain and Ireland, come from the north on the ſurface of the ſea; their approach is known by the hovering of ſea fowl in expectation of prey, and by the ſmoothneſs of the water; but where they breed, or what particular place they come from, cannot be eaſily diſcovered. As this great ſhoal paſſes between the ſhores of Greenland and the north cape, it is probably confined, and as it reaches the extremities of Great-Britain, is neceſſarily divided into two parts. For we find one part of the herrings ſteering weſt, or ſouth-weſt, and leaving the iſlands of Shetland and Orkney to the left, paſs on towards Ireland, where being interrupted a ſecond time, ſome keeping the ſhore of Britain, paſs away ſouth down St. George's channel; while the other part, edging off to the ſouth-weſt, coaſt the weſtern ocean, till they reach the ſouth ſhore of Ireland, and then ſteering ſouth-weſt, join the reſt in St. George's channel. The other part of the firſt diviſion made in the north, parting a little to the eaſt and ſouth-eaſt, paſs by Shetland, and then make the point of Buchan-neſs, and the coaſt of Aberdeen, filling as they go, all the bays, firths, creeks, &c. with their innumerable multitudes. Hence they proceed forward, paſs by Dunbar, and rounding the high ſhores of St. Abbe's Head, and Berwick, are ſeen again off Scarborough; and even then not diminiſhed in bulk, till they come to Yarmouth roads, and from thence to the mouth of the Thames, after which, paſſing down the Britiſh Channel, they ſeem to be loſt in the Weſtern ocean.

The vaſt advantage of this fiſhery to our nation is very obvious, when we conſider, that though herrings are found upon the ſhores of North America, they are never ſeen there in ſuch quantities as with us, and that they are not to be met with in conſiderable numbers in any of the ſouthern kingdoms of Europe, as Spain, Portugal, or the ſouth parts of France on the ſide of the ocean, or in the Mediterranean, or on the coaſt of Africa. There are two ſeaſons for fiſhing herrings, the firſt from June to the end of Auguſt, and the ſecond in autumn, when the fogs become very favourable for this kind of fiſhing. The Dutch begin their herring-fiſhing on the 24th of June, and employ no leſs than two thouſand veſſels therein called buſſes, being between forty-five and ſixty tons burden, and carrying three or four ſmall cannon. They never ſtir out of port without a convoy, unleſs there be enough together to make about eighteen or twenty cannon among them, in which caſe they are allowed to go in company. Before they go out, they make a verbal agreement, which has the ſame force as if it were in writing. The regulations of the admiralty of Holland are partly followed by the French, and other nations, and partly improved and augmented with new ones, as, that no fiſher ſhall caſt his net within a hundred fathoms of another boat: that while the nets are caſt, a light ſhall be kept on the hind part of the veſſel: that when a boat is by any accident obliged to leave off fiſhing, the light ſhall be caſt into the ſea: that when the greater part of a fleet leaves off fiſhing, and caſts anchor, the reſt ſhall do the ſame, &c. By the late act of parliament in Great Britain, the regulations are, that every veſſel intitled to the bounty, muſt carry twelve Winchester buſhels of ſalt in new barrels, for every laſt of fiſh ſuch veſſel is capable of holding; and as many more new barrels as ſuch veſſels can carry; and two fleets of tanned nets, that is, a veſſel of ſeventy tons ſhall carry one fleet of fifty nets, each net to be thirty yards full upon its rope, and ſeven fathoms deep; and ſo in proportion for greater or ſmaller veſſels; and be provided with one other fleet of fifty like nets, on board a tender, or left on ſhore in a proper place for the uſe of the ſaid veſſel, &c.

There is nothing particular in the manner of fiſhing. The nets wherein the fiſh are drawn, ſhould regularly have their meſhes an inch ſquare to let all the leſſer fry go through.

Curing and preparing HERRING. The commerce of herring, both white or pickled, and red, is very conſiderable. The white Dutch herrings are the moſt eſteemed, being diſtinguiſhed into four ſorts, according to their ſizes; and the beſt are thoſe that are fat, fleſhy, firm, and white, ſalted the ſame day they are taken with good ſalt, and well barrelled. The Britiſh herrings are little inferior, if not equal to the Dutch; for in ſpite of all their endeavours to conceal the ſecret, their method of curing, laſting, or caſking the herrings, has been diſcovered, and is as follows. After they have hauled in their nets, which they drag in the ſterns of their veſſels backwards and forwards in traverſing the coaſt, they throw them upon the ſhip's deck, which is cleared of every thing for that purpoſe: the crew is ſeparated into ſundry diviſions, and each diviſion has a peculiar taſk: one part opens and guts the herrings, leaving the melts and roes; another cures and ſalts them, by lining or rubbing their inſide with ſalt; the next packs them, and between each row and diviſion they ſprinkle handfuls of ſalt; laſtly, the cooper puts the finiſhing hand to all, by heading the caſks very tight, and ſtowing them in the hold. It is cuſtomary with us to waſh the herrings in freſh water, and ſteep them twelve or fifteen hours, in a ſtrong brine, before we proceed to barrel them.

Red HERRINGS muſt lie twenty-four hours in the brine, inaſmuch as they are to take all their ſalt there, and when they are taken out, they are ſpitted, that is, ſtrung by the head on little wooden ſpits, and then hung in a chimney made for that purpoſe: after which, a fire of bruſh-wood which yields a deal of ſmoke, but no flame, being made under them, they remain there till ſufficiently ſmoked and dried, and are afterwards barrelled up for keeping.

HERSE, in fortification, is a lattice or portcullice, made in the form of a harrow, and ſtuck full of iron-ſpikes.

It is uſually hung by a rope, faſtened to a mouliner, which is cut in caſe of ſurprize, or when the firſt gate is broken with a petard, to the end that it may fall and ſtop up the paſſage of the gate, or other entrance of a fortreſs.

Theſe herſes are alſo often laid in the roads, with the points upwards, to incommode the march both of the horſe and infantry.

HERSILLON, in the military art, a ſort of beam, &c. between ten and twelve feet long, whoſe two ſides are full of ſpikes, to incommode both horſe and foot.

The word is a diminutive of the preceding.

HESPER, *Heſperus*, in aſtronomy, the evening ſtar, Venus being ſo called when ſhe ſets after the ſun.

The word is Greek, Εσπερος, the brother of Atlas, and father of the Heſperides.

HESPERIDES, in the ancient mythology, were the daughters of Heſperus, which were three in number, Ægle, Arethuſa, and Heſperethuſa. They are repreſented by the ancients as having the keeping of certain golden apples on the other ſide the ocean. The poets aſſign them a dragon to watch the fruit: this dragon Hercules ſlew, and and carried off the apples.

HESPERIS, dame violet, in botany, a genus of plants, the corolla of which conſiſts of four cruciform petals, of an oblong figure, of the length of the cup, a little reflex, and ending in ſmall ungues: the fruit is a long pod, plane, compreſſed, ſtriated, bilocular, bivalve, containing ſeveral oval, compreſſed ſeeds.

HETEROCLITE, among grammarians, one of the three variations in irregular nouns, and defined by Ruddiman

Ruddiman a noun that varies in declenſion; as *hoc vas, vaſis*; *hæc vaſa, vaſorum*.

Other grammarians take the word heteroclite in a larger ſenſe, applying it to all irregular nouns. See ANOMALOUS.

The heteroclite nouns properly ſo called, or according to the definition, are only three, viz. *vas*, *jugerum*, and *domus*.

HETERODOX, in polemical theology, any thing contrary to the faith and doctrines of a true church.

HETERODROMUS VECTIS, in mechanics, a lever, wherein the fulcrum, or point of ſuſpenſion, is placed between the power and the weight. See the article LEVER.

HETEROGENEOUS, or HETEROGENEAL, ſomething that conſiſts of parts of diſſimilar kinds, in oppoſition to homogeneous. See HOMOGENEOUS.

HETEROGENEOUS, in mechanics, ſuch bodies whoſe denſity is unequal in different parts of their bulk; or they are ſuch whoſe gravities in different parts are not proportionable to the bulks thereof: whereas bodies equally denſe or ſolid in every part, or whoſe gravity is proportionable to their bulk, are ſaid to be homogeneous.

HETEROGENEOUS LIGHT is, by Sir Iſaac Newton, ſaid to be that which conſiſts of rays of different degrees of refrangibility: thus the common light of the ſun or clouds is heterogeneous; being a mixture of all ſorts of rays.

HETEROGENEOUS NOUNS, one of the three variations in irregular nouns; or ſuch as are of one gender in the ſingular number, and of another in the plural, as *hoc cælum, hi cæli*. Heterogeneous, under which are comprehended mixed nouns, are ſix-fold. 1. Thoſe which are of the maſculine gender in the ſingular number, and neuter in the plural, as *hic tartarus, hæc tartara*. 2. Thoſe which are maſculine in the ſingular number, but maſculine and neuter in the plural, as *hic locus, hi loci, et hæc loca*. 3. Such as are feminine in the ſingular number, but neuter in the plural, as *hæc carabaſus, et hæc carabaſa*. 4. Such nouns as are neuter in the ſingular number, but maſculine in the plural, as *hoc cælum, hi cæli*. 5. Such as are neuter in the ſingular, but neuter and maſculine in the plural, as *hoc raſtrum; hi raſtri, et hæc raſtra*; and, 6. Such as are neuter in the ſingular, but feminine in the plural number, as *hoc epulum, hæ epulæ*.

HETEROGENEOUS NUMBERS, mixed numbers, conſiſting of integers and fractions. See INTEGER and FRACTION.

HETEROGENEOUS QUANTITIES are thoſe which are of ſuch different kinds, as that one of them taken any number of times, never equals or excels the other.

HETEROGENEOUS SURDS are ſuch as have different radical ſigns, as $\sqrt[3]{aa}$, $\sqrt[3]{bb}$, $\sqrt{9}$, $\sqrt{18}$, &c. See SURD.

HETEROSCII, in geography, commonly denotes thoſe inhabitants of the earth in the temperate zones, whoſe ſhadow at noon is always projected the ſame way, either northward or ſouthward.

The word is Greek, and compounded of ἕτερος, different, and σκια, a ſhadow.

Heteroſcii however, ſtrictly, denotes thoſe inhabitants which, during the whole year, have their noon-tide ſhadows projected different ways from each other. Thus the inhabitants of the northern temperate zone are heteroſcii with regard to thoſe of the ſouthern. The inhabitants of one part of the torrid zone are heteroſcii with regard to thoſe of the reſt, and to thoſe of one of the temperate zones, except at the ſolſtices; and even at that time, all of the torrid zone are heteroſcii with regard to thoſe of the temperate zones: but as the people of the torrid zone have their ſhadow now on this, and then on that ſide, they are called amphiſcii. See AMPHISCII.

HETEROUSIANS, a name compoſed of ἕτερος, other, and ουσια, ſubſtance; being given to a ſect of Arians, who did not believe that the Son of God was of a ſubſtance like to that of the Father, which was the opinion of another branch of the Arians, who were from thence called Hemoouſians; but that he was of another ſubſtance, different from that of the Father.

HEXACHORD, in ancient muſic, a concord called by the moderns a ſixth.

HEXAEDRON, *Hexahedron*, in geometry, one of the Platonic or five regular bodies, being a ſolid conſiſting of ſix equal ſides or faces, popularly called a cube.

The word is Greek, and derived from ἑξ, ſix, and ἑδρα, baſe. The ſquare of the ſide of a hexaedron is in a ſubtriple ratio to the ſquare of the diameter of the circumſcribed ſphere. Hence the ſide of the hexaedron is to the ſide of the ſphere it is inſcribed in, as 1 to $\sqrt{3}$, and conſequently incommenſurable thereto.

HEXAGON, in geometry, a figure of ſix ſides, and as many angles.

The word is Greek, and compounded of ἑξ, ſix, and γωνια, an angle.

If the ſides and angles be equal, it is called a regular hexagon. The ſide of a regular hexagon inſcribed in a circle is equal to the radius of that circle; hence a regular hexagon is inſcribed in a circle, by ſetting the radius off ſix times upon the periphery: As 1 to 1.672, ſo is the ſquare of the ſide of any regular hexagon to the area thereof nearly.

To deſcribe a hexagon on a given line AB (plate LXXIII. *fig.* 7.) draw an equilateral triangle ABC, and the vertex C will be the center of a circle, which will circumſcribe the hexagon required.

HEXAMETER, in the Greek and Latin poetry, a verſe conſiſting of ſix feet.

The word is Greek, and compounded of ἑξ, ſix, and μετρον, meaſure.

The firſt four feet of a hexameter may be either dactyls or ſpondees; but the laſt foot ſhould in ſtrictneſs be a ſpondee, and the laſt but one a dactyl, as in Homer and Virgil.

Hexameters are divided into heroic, which ſhould be grave and majeſtic; and into ſatyrical, which may be more negligent, as thoſe of Horace. Epic poems conſiſt of hexameters alone; elegies and epiſtles ordinarily conſiſt of hexameters and pentameters alternately.

The modern languages are not at all fit for this kind of verſe, whoſe cadence depends altogether on long and ſhort ſyllables.

HEXANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and ſix ſtamina, or male parts in each, which are in ſome plants all of the ſame length, and in others are alternately one ſhorter and another longer.

The word is derived from the Greek, ἑξ, ſix, and ανηρ, male.

The plants of this claſs are garlic, hyacinth, meadow ſaffron, &c.

HEXAPLA, in church-hiſtory, a work publiſhed by Origen, containing a part of the Old Teſtament in the original Hebrew, with ſeveral verſions of it in ſix columns; from whence it was called hexapla, or the ſixfold edition.

HEXASTYLE, in architecture, a building with ſix columns in front.

HIATUS properly ſignifies an opening, chaſm, or gap; but it is particularly applied to thoſe verſes where one word ends with a vowel, and the following word begins with one, and thereby occaſion the mouth to be more opened, and the ſound to be very harſh.

The term hiatus is alſo uſed in ſpeaking of manuſcripts, to denote their defects, or the parts that have been loſt or effaced. See MANUSCRIPT.

HICCUP, or HICCOUGH, *Singultus*, in phyſic, a ſpaſmodic, convulſive, interrupted, and uneaſy concuſſion of the diaphragm and ſome of the parts affixed to it, made in inſpiration, and accompanied with a ſonorous exploſion of the air through the mouth.

Hiccups are divided into two ſpecies; the former, when the immediate cauſe of the diſorder is lodged in the diaphragm itſelf; and the latter, when the cauſe reſides in the ſtomach, whoſe vellication is propagated to the diaphragm.

The weaker the nervous ſyſtem, the more readily any perſon is ſeized with this diſorder. Hence infants, children, and old people are more ſubject to the hiccup than others; ſo that they eaſily fall into that tranſitory ſpecies of the diſorder, which is produced by a refrigeration of the ſtomach, eating greedily, or drinking exceſſively of cold liquors, or laughter. But the more remote cauſes

which concur to promote a morbid hiccup, which requires the phyſician's aid, eaſily exert their influence on ſuch perſons, and are as follows:

This diſorder then is readily produced by a cold moiſture, eſpecially when the patient is hot.

Aliments either of a bad quality, or uſed in too large a quantity, produce an hiccup.

Whatever aliments are either too acrid of themſelves, or from various cauſes degenerate within the ſtomach into acrid and viſcid ſordes, capable of vellicating its coats, produce a more or leſs violent hiccup.

Acrid and corrupted humors, impregnated with many ſaline parts, and acting on the diaphragm, excite the quickeſt and generally fatal exagitations of it.

An acute hiccup is the concomitant of ſuch diſorders as have a quick and ſpeedy termination, of which the moſt conſiderable are inflammations of the more noble parts of the viſcera.

An hiccup generally accompanies continual, malignant, and exanthematous fevers, when various remote cauſes concur to its production.

To the acute hiccups of a dubious event, we muſt alſo refer thoſe which ſucceed inanition, or too large an excretion of the humours.

A chronical hiccup ſometimes riſes from a peccant ſtate of the blood and humours, and from the faults or bad conformation of the bony parts ſurrounding the breaſt.

Every hiccup does not require a cure; but a morbid hiccup calls for the aſſiſtance of the phyſician, as hath been already obſerved, who is principally to follow three intentions of cure; the firſt is to mitigate and allay the preternatural, ſpaſmodic, and convulſive motions; the ſecond is to remove the material cauſes; and the third is to reſtore the parts affected and weakened.

The firſt intention is anſwered by gentle antiſpaſmodic and anodyne ſubſtances, as amber, cinnamon, ſaffron, and caſtor. An ounce and a half of the oil of ſweet almonds, mixed with a few drops of the diſtilled oil of dill, is by ſome thought a ſpecific for the hiccup.

But the phyſician is chiefly to purſue the ſecond intention, which is to remove the material cauſes. The peccant matter is therefore to be duly concocted, and then to be eliminated either by vomit or ſtool; the former is anſwered by four or ſix grains of the powder of ſquills, mixed with three grains of purified nitre; and the latter by preparations of manna and rhubarb.

The celebrated Sydenham tells us that he has cured people in years of this diſorder, by giving them two drams of diaſcordium at a doſe, when the ſeeds of dill and other celebrated ſpecifics have proved ineffectual.

HIDE, the ſkin of beaſts, but particularly applied to thoſe of large cattle, as bullocks, cows, horſes, &c. See SKIN.

HIDE *of Land* was ſuch a quantity of land as might be plowed with one plough within the compaſs of a year, or ſo much as would maintain a family; ſome call it ſixty, ſome eighty, and ſome an hundred acres.

The diſtribution of this kingdom by hides of land is very ancient, mention being made of it in the laws of king Ina. Henry I. had three ſhillings for every hide of land, in order to raiſe a dowry for his daughter: this tax was called hidage.

HIDE-BOUND, among farriers, a diſtemper in horſes when the ſkin ſticks ſo faſt to the back and ribs, that the hand cannot ſeparate the one from the other without great difficulty; his body is at the ſame time lean, his back-bones ſtand up, his guts are for the moſt part deficient in moiſture, and his dung dry and more offenſive than common.

If a horſe become hide-bound by hard riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or ſome other diſeaſe, if that be cured which is the cauſe, the effect will ceaſe; but if he has no fever upon him, and he is hide-bound only from lowneſs of blood and ſpirits, give him boiled barley, white-water, or the like, and when his fleſh is raiſed, harden it with good oats, beans, and moderate exerciſe.

HIERACHIUM, hawkweed, in botany, a genus of plants, the compound flower of which is imbricated and uniform, conſiſting of a great number of equal hermaphrodite cotolluläe, which are linear, truncated, and quinquedentated: the ſtamina are five very ſhort capillary filaments: the ſeeds are ſolitary, obtuſely quadragonal, and winged with down.

HIERACITES, *Hieracitæ*, in church-hiſtory, Chriſtian heretics in the third century, ſo called from their leader Hierax, a philoſopher of Egypt; who taught that Melchiſedec was the Holy Ghoſt, denied the reſurrection, and condemned marriage: he likewiſe held, that no one could be ſaved who died before he arrived at years of diſcretion. The diſciples of Hierax taught that the word, or Son of God, was contained in the Father, as a little veſſel is contained in a great one; from whence they had the name Metangimoniſts, from the Greek word μεταγγιμοι, which ſignifies contained in a veſſel.

HIERARCHY, among divines, denotes the ſubordination of angels. See the article ANGEL.

Some of the rabbins reckon four, others ten, orders or ranks of angels; and give them different names, according to their different degrees of power and knowledge. Dionyſius the Areopagite, the jeſuit Celert, and many others, have gone ſo far as to ſettle a kind of ceremonial or rule for the precedency of angels, as ſeraphim, cherubim, thrones, dominions, principalities, &c.

HIERARCHY likewiſe denotes the ſubordination of the clergy, eccleſiaſtical polity, or the conſtitution and government of the Chriſtian church, conſidered as a ſociety.

HIEROGLYPHICS, in antiquity, myſtical characters, or ſymbols, in uſe among the Egyptians, and that as well in their writing as inſcriptions; being the figures of various animals, the parts of human bodies, and mechanical inſtruments.

But beſides the hieroglyphics in common uſe among the people, the prieſts had certain myſtical characters, in which they wrapped up and concealed their doctrines from the vulgar. It is ſaid, that theſe ſomething reſembled the Chineſe characters, and that they were the invention of Hermes. Sir John Marſham conjectures, that the uſe of theſe hieroglyphical figures of animals, introduced the ſtrange worſhip paid them by that nation; for as their figures were made choice of, according to the reſpective qualities of each animal, to expreſs the qualities and dignity of the perſons repreſented by them, who were generally their gods, princes, and great men, and being placed in their temples, as the images of their deities; hence they came to pay a ſuperſtitious veneration to the animals themſelves.

HIEROGRAMMATISTS, ἱερογραμματεῖς, i. e. holy regiſters, were an order of prieſts among the ancient Egyptians, who preſided over learning and religion.

They had the care of the hieroglyphics, and were the expoſitors of religious doctrines and opinions.

HIGH, *Altus*, a term of relation, importing one thing's being ſuperior or above another: thus we ſay, a high mountain, the high court of parliament, high relievo, &c.

HIGH, in muſic, is ſometimes uſed in the ſame ſenſe with loud, and ſometimes in the ſame ſenſe with acute.

HIGH-WATER, the ſtate of the tide when higheſt, or the time juſt before it begins to ebb. See the article TIDE.

HIGH-WAY, a free paſſage for the king's ſubjects, on which account it is called the king's high-way, though the freehold of the ſoil belong to the lord of the manor, or the owner of the land. Thoſe ways that lead from one town to another, and ſuch as are driſt or carr-ways, and are for all travellers in great roads, or that communicate with them, are high-ways only; and as to their reparation, are under the care of ſurveyors.

HIGHNESS, a title given to princes. Before king James I. the kings of England had no other title but that of highneſs; which was alſo the caſe of the kings of Spain before Charles V.

At preſent all the ſons of crowned heads are ſtiled royal highneſs, as the electors of Germany are electoral highneſs.

HIS TESTIBUS, a phraſe anciently added in the end of a deed, written in the ſame hand with the deed; upon which the witneſſes were called, the deed

read, and their names entered. See the article WITNESS.

His teſtibus, in ſubject deeds, continued till, and in, the reign of Henry VIII.

HILARIA, an ancient Roman feſtival, obſerved on the eighth of the calends of April, or the 25th day of March, in honour of the goddeſs Cybele. It was ſo called from the various expreſſions of joy and mirth on this occaſion.

HILARY-TERM, among lawyers. See TERM.

HILL, in the natural hiſtory of the earth. See MOUNTAIN.

Hills are of great uſe in a garden, as,

1. They ſerve as ſcreens to keep off the cold and nipping blaſts of the northern and eaſtern winds.

2. The long ridges and chains of lofty mountains, being generally found to run from eaſt to weſt, ſerve to ſtop the evagation of thoſe vapours towards the poles, without which they would all run from the hot countries, and leave them deſtitute of rain.

3. They condenſe thoſe vapours, like alembic heads, into clouds; and ſo, by a kind of external diſtillation, give origin to ſprings and rivers; and, by amaſſing, cooling, and conſtipating them, turn them into rain, and by that means render the fervid regions of the torrid zone habitable.

4. They ſerve for the production of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experiment and calculation, that hills, though they meaſure twice as much as the plain ground they ſtand upon, yet the produce of the one can be no more than the other; and therefore, in purchaſing land, the hills ought not to be bought for more than their ſuperficial meaſure, i. e. to pay no more for two acres upon the ſide of an hill, than for one upon the plain, if the ſoil be equally rich.

It is true, that thoſe lands that are hilly and mountainous, are very different, as to their valuable contents, from what are found in flat and plain ground, whether they be planted, ſown, or built upon; as for example:

Suppoſe an hill contains four equal ſides, which meet in a point at the top; yet the contents of theſe four ſides can produce no more grain, or bear no more trees, than the plain ground on which the hill ſtands, or than the baſe of it; and yet by the meaſure of the ſides there may be double the number of acres, rods, and poles, which they meaſure on the baſe or ground-plot.

For as long as all plants preſerve their upright method of growing, hilly ground can bear no more plants in number than the plain at the baſe.

Again, as to building on an hill, the two ſides of an hill will bear no more than the ſame number of houſes that can ſtand in the line at the baſe.

And as to rails, or park-paling over an hill, though the meaſure be near double over the hill to the line at the bottom, yet both may be incloſed by the ſame number of pales of the ſame breadth. *Miller's Gard. Dict.*

HIN, a Hebrew meaſure of capacity for things liquid, containing the ſixth part of an epha, or one gallon two pints, or two thouſand five hundred and thirty-three ſolid inches, Engliſh meaſure.

HIND, a female ſtag in the third year of its age.

HIND CALF, a male hart, or hind, in the firſt year. She fawns in April or May.

HIND, or HINE, a huſbandman's ſervant. Thus a perſon who overſees the reſt, is called the maſter hine.

HINGES, in building, thoſe iron joints, whereby doors, tables, &c. open, ſhut, or fold, &c. Of theſe there are various ſpecies.

HIP, dog-roſe, a ſpecies of wild briar, with ſingle pentapetalous flowers, of a whitiſh colour, mixed with various ſhades of red. It is one of the largeſt plants of the roſe kind; grows wild in hedges; and flowers, as the garden ſorts, in June.

The flowers of this ſpecies, of an agreeable but weak ſmell, and in taſte bitteriſh and roughiſh, are ſaid to have a greater degree of laxative virtue than thoſe of the damaſk roſe, together with a mild corroborating or reſtringent quality. The fruit, the only part of the dog-roſe made uſe of in medicine among us, is agreeably dulcoacid, and ſtands recommended as a cooling reſtringent, in bilious fluxes, ſharpneſs of urine, and hot indiſpoſitions of the ſtomach: the freſh pulp is made in the ſhops into a conſerve, by mixing three ounces of it with five of fine ſugar. The pulp ſhould be ſeparated with great care from the rough prickly matter which incloſes the ſeeds; a ſmall quantity of which, retained in the conſerve, is apt to occaſion an uneaſineſs at the ſtomach, pruritus about the anus, and ſometimes vomiting.

HIP-GOUT, *Sciatica*. See the articles GOUT and SCIATICA.

HIP-MOULD is by ſome uſed for the back of the hip, but others underſtand it to mean the prototype or pattern, commonly made of a thin piece of wainſcot, by which the back and ſides of the hip are ſet out.

HIP-ROOF, among carpenters, called alſo Italian roof, is a roof which has neither gable-head, ſhread-head, nor jerken-head, by which is meant ſuch heads as are both gable and hip at the ſame end; for it is a gable or upright as high as the collar-beam, and then there are two ſhort hips, which ſhut up with their tops to the tops of a pair of rafters, which country carpenters call ſinglars. A hip-roof has rafters as long, and with the angles of the foot, &c. at the ends of buildings, as it has at the ſides; and the feet of the rafters at the ends of ſuch buildings as have hip-roofs, ſtand on the ſame plane, viz. parallel with the horizon, and at the ſame height from the foundation, with rafters on the ſides of the roof.

HIPPEUS, in phyſiology, a kind of comet, ſo called from its reſemblance to a horſe. See the article COMET.

HIPPOCAMPUS, the ſea-horſe, in ichthyology, the ſquare-bodied ſyngnathus, with no fin at the tail. It is five inches long, and where thickeſt, about an inch in diameter; the head is long, ſlender, and compreſſed, forming a kind of ſnout; the body is of a quadrangular figure, but the diviſions are not equal, and in the thickeſt part it is hexangular or heptangular.

It is a very ſingular and rare fiſh; the tail of which uſually curls up in the drying, and its head being bent down, gives it a rude reſemblance to a horſe; whence the name.

HIPPOCENTAUR, in antiquity, a fabulous animal, half man half horſe.

What gave riſe to the fable of hippocentaurs, was this. The Theſſalians are ſaid to have been the firſt inventors of the art of breaking horſes; and being firſt ſeen on horſeback, they ſeemed to make but one body with the horſes; whence the origin of the fable.

HIPPOCRAS, an infuſion of aromatic powders in wine, which is afterwards edulcorated with ſugar and honey; being ſo called becauſe that, when the infuſion is finiſhed, it is ſtrained through Hippocrates's ſleeve.

It is prepared of various aromatics and other ingredients, according to the different intentions to be anſwered.

HIPPOCRATES's SLEEVE, a kind of filtre or ſtraining bag formed by joining the oppoſite angles of a ſquare piece of flannel in form of a pyramid, and uſed to ſtrain ſyrups, decoctions, &c. for clarification.

HIPPODROME, in antiquity, the courſe where horſe-races were performed.

HIPPOPOTAMUS, the river horſe, a genus of quadrupeds, of the order of the jumenta, the characters of which are theſe: the fore-teeth of the upper jaw are four, and placed in pairs; thoſe of the lower jaw are prominent, and the intermediate ones are protended forward: the canine teeth are ſingle, and obliquely truncated; the teats are only two, and placed near the groin.

The hippopotamus is a native of Africa, paſſing a great part of its time under water, in the rivers of the Nile and Niger; but comes on ſhore to ſleep and breed. It is a large unwieldy animal, as big as an ox.

HIRCUS, in anatomy, a part of the auricle or outer ear, being that eminence next the temples. See the article EAR.

HIRCUS, a goat, in aſtronomy, a ſtar of the firſt magnitude, the ſame with capella. See CAPELLA.

HIRCUS is alſo a name uſed by ſome writers for a comet encompaſſed, as it were, with a mane, ſeemingly rough and hairy.

HIRUDO, the leech, in zoology, a well known naked inſect, with a flatted but not jointed body, and broader at the end than elſewhere, and the ſkin ſoft and gloſſy.

The common leech grows to two or three inches in length, and is of a blackiſh colour, variegated with yellow.

HISPID LEAF, among botaniſts, one whoſe ſurface is covered with more thick and rigid hairs than the piloſe leaves are.

HISPID STALK, among botaniſts, a ſtalk roughly hairy.

HISSING LETTERS, among grammarians, are S, X, and Z, ſo called on account of their harſh ſound.

HISTORICAL, ſomething that relates to hiſtory: thus we ſay, hiſtorical truth, hiſtorical ſtyle, hiſtorical narration of facts, &c. See the article HISTORY.

HISTORIOGRAPHER, a profeſſed hiſtorian, or writer of hiſtory.

HISTORY, an account, properly ſpeaking, of paſt tranſactions, narrated with ſuch important circumſtances as are proper to be tranſmitted to poſterity, and that in a regular continued ſeries.

Hiſtory is, of all others, the moſt difficult province. In other ſubjects there is a greater latitude for the writer's imagination; but, in hiſtory, he is confined to the occurrences he relates; and theſe, as they are not alike entertaining, require force and judgment in the narration to make them all agreeable. The richeſt fields of hiſtory are ſcenes of action and commotion, where nations are agitated by wars abroad, or factions at home. The moſt delicate part of an hiſtorian, which requires the deepeſt penetration, and ſoundeſt judgment, are the councils of ſtates and princes, the ſprings of action, the characters of men, the intereſt of parties, their different views, &c. Hiſtory will not admit thoſe decorations other ſubjects are capable of: the paſſions are not to be moved with any thing but the truth of the narration. All the force and beauty muſt lie in the order and expreſſion. To relate every event with perſpicuity, in ſuch words as beſt expreſs the nature of the ſubject, is the chief commendation of an hiſtorian's ſtyle. The colours facts are painted in, the ſtrength and ſignificancy of the ſeveral actions, the regular confuſion of a battle, the diſtractions of a tumult ſo ſenſibly depicted, that in reading we ſeem to ſee them; this is the art and perfection of an hiſtorical ſtyle. An hiſtorian muſt not only write impartially, but nobly. He that ſpeaks to the whole world, and to all ages, that is the inſtructor of mankind, that pronounces the deſtiny of ſo many great men, and fixes their character with poſteritity, what ſtrength of genius can be ſufficient for ſo important an enterprize? He muſt be capable of forming great and noble conceptions of things, and giving ſuch an exalted turn to his narration, as may truly comport with the dignity of his ſubject.

During the firſt ages, we have little or no hiſtory of the tranſactions of mankind, but that of Moſes, whoſe account is chiefly confined to the riſe, religion, laws, and government of the Jews. It is preſumed he wrote the principal part of his hiſtory about the year of the world 2550, and had good opportunities of knowing the truth of his relations. He gives a regular account of the Jewiſh affairs, from the creation to the year 2550: from this period the ſacred hiſtory is carried on by different writers, and continued down in the books of Joſhua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra, and Nehemiah, to the year of the world 3581.

As to prophane hiſtory, till almoſt the time where the Scripture records end, we have little remains of it, but what are either broken and confuſed, or fabulous: for, from the creation to the flood, we have no credible account of things, but that of Moſes; and from the flood to the reign of Cyrus, the remains of antiquity are ſo broken and confuſed, that we have little prophane hiſtory of credit during this long and dark period. As to the Chaldean Hiſtory of Beroſus, and the Egyptian of Manetho, they were both wrote ſince Herodotus, and we have only ſome fragments of them preſerved by Joſephus, Euſebius, &c. As to Sanchoniathon, who has given us the Phœnician hiſtory, though he pretends to be much more ancient, yet his great antiquity has been juſtly queſtioned by Scaliger, and his very exiſtence by Mr. Dodwell.

The Greeks, as they have not been noted for their veracity in any reſpect, ſo their integrity in this particular has been always ſo queſtionable, that *Græcia mendax* has been ſtigmatized in hiſtory. We have no tolerable account from them before the Olympiads; the times before theſe were the fabulous ages; and when the hiſtorical commences, our accounts are not much better; for, not having had originally any public annals, and amongſt their ancient authors the poets having the firſt ſtroke, we may eaſily imagine what accounts are to be expected from thoſe, who are either to follow uncertain traditions, or the poets. Accordingly their firſt accounts were very looſe, and rather poems than hiſtories, which they have been charged with by the Romans, and particularly Quintilian compares the liberty they took to a poetic licenſe: but Joſephus tells them their accounts of things are all novel; that they have no author more ancient than Homer; that Hellanicus differs from Acuſilaus; he corrects Heſiod, and Hellanicus Ephorus; he again is corrected by Timæus, as he is by others, and Herodotus by all, who has been ſtyled the father of hiſtory, though he might with equal juſtice be called the parent of fable.

The hiſtorians from whom the Grecian and Roman hiſtory may be collected, are Thucydides, Diodorus Siculus, Lucian, Juſtin, Xenophon, Cteſias, Polybius, Dionyſius Halicarnaſſeus, Philo, Apion, Cornelius Nepos, Q. Curtius, Plutarch, Ælian, Arrian, Appian, Diogenes Laertius, Dio Caſſius, Herodian, Eunappus, Zoſimus, and Photius.

As to the Roman Hiſtory, it at firſt only conſiſted of ſimple notes drawn up by the pontifex maximus, who regularly ſet down every year whatever paſſed of conſiderable moment in the ſtate, either in war or peace; and this cuſtom, eſtabliſhed very early at Rome, ſubſiſted till the year A. U. C. 629, or 631. Theſe memoirs were called the great annals. Hiſtory now began to quit this antique garb, and to appear in public with more decency. The poets were the firſt who conceived a deſign of improving and adorning it. Nævius compoſed a poem on the firſt Punic war, and Ennius wrote the annals of Rome in heroic verſe. Hiſtory at length aſſumed a regular form, and appeared in proſe. Q. Fabius Victor is the moſt ancient of the Latin hiſtorians; he lived in the time of the ſecond Punic war. The hiſtorians whoſe writings are come down to us are Salluſt, Livy, Cæſar, Paterculus, Tacitus, Q. Curtius, Suetonius, Lucius Florus, Juſtin, Aurelius Victor, Ammianus Marcellinus, and Eutropius. Authors of the lives of the Roman emperors, from Adrian to Carinus, are Spartianus, Lampridius, Vulcatius, Capitolinus, Pollio, and Vopiſcus, who all lived in the reign of Dioclefian. If we have regard to only one condition of hiſtory, namely, its truth, we ſhall find that moſt of the above authors are faulty in that particular.

Le Moyne only allows four hiſtorians among the Romans, and not ſo many among the Greeks, and all of them ſhort of perfection; and as to the moderns, he is yet more ſcrupulous in admitting them into account.

There are ſome works in Engliſh very uſeful for the underſtanding of ancient hiſtory, as Hind's Hiſtory of Greece, Potter's Greek Antiquities, Lewis's Hebrew Antiquities, Kennet and Danet's Roman Antiquities, Prideaux and Shuckford's Connexions, Echard's Roman Hiſtory, Tranſlation of Joſephus, Rollin's Ancient Hiſtory, Univerſal Hiſtory, Bundy's Tranſlation of the Roman Hiſtory, Nicholſon's Hiſtorical Library, Kearne's *Diſſertatio Hiſtoricus*, and Rawlinſon's Method of Studying Hiſtory; the two laſt particularly will give the reader a general view of univerſal hiſtory, and direct to the beſt editions of almoſt all the hiſtorians extant.

As to the hiſtorical accounts of thoſe nations that grew out of the ruins of the Roman empire, which included the greateſt part of the known world, the beſt hiſtories in that way are Salmon's Modern Hiſtory, Sir Walter Raleigh's Hiſtory of the World, Mezeray's and Daniel's Hiſtory of France, Le Clerc's Hiſtory of the United Provinces, Mariana's Hiſtory of Spain, Meieus's Hiſtory of Flanders, Heuterus's Hiſtory of Burgundy, Bonfinius's Hiſtory of Hungary, Cromerius's Hiſtory of Poland, Aventinus's Hiſtory of Bavaria, Le Quien's Hiſtory of Portugal,

Vertot's Revolutions of Portugal and Sweden, &c. The Germans and Italians abound with particular memoirs of their different ſtates and governments, but have no complete body of hiſtory. The only hiſtorians that have given us a large and comprehenſive view of the Hiſtory of England, are Echard, Rapin, Hume, and Smollett.

Beſides theſe four, we have alſo the particular hiſtories of ſeveral prince's reigns, as Sir Francis Bacon's Hiſtory of Henry VII. Clarendon's Hiſtory of the Rebellion, Sir William Temple's Introduction to the Hiſtory of England. There is alſo Camden's Britannia, Tyrrel's Hiſtory of England, Buchanan's and Duff's Hiſtory of Scotland, Sir James Ware and Cox's Hiſtory of Ireland, &c.

Thuanus and biſhop Burnet, &c. have written the hiſtory of their own times.

The great diſadvantage our moſt celebrated hiſtorians ſeem to labour under, is too tedious an interruption by the inſertion of laws, ſtatutes, and records in the body of their narration, at leaſt in making too copious a recital of them; whereas they had better have been mentioned only in general, and thrown by themſelves into an appendix.

Hiſtory is diſtinguiſhed with regard to its matter and its form; with regard to its matter, it is either ſacred or natural, civil, perſonal, or ſingular.

Method of ſtudying HISTORY. Perſons who read hiſtory merely for amuſement, or having in view ſome particular branch of learning, attend only to certain branches of hiſtory, are not confined to that order and connection, which is abſolutely requiſite for obtaining a proper knowledge of hiſtory; the moſt regular, as well as ſucceſsful way of ſtudying which, is to begin with an epitome of univerſal hiſtory, and afterwards apply to the hiſtory of particular nations and commonwealths: for the ſtudy of particular hiſtories preſuppoſes, or to ſpeak more properly, is only extending the knowledge of particular parts of univerſal hiſtory. Unleſs this be our plan, we ſhall only fill the memory with ſome events, which may be done without applying to hiſtory, or pretending to the knowledge of it.

HISTORY, in painting, denotes a picture compoſed of divers figures, or perſons, repreſenting ſome tranſaction, either real or feigned. See PAINTING.

Natural HISTORY. See NATURAL.

HISTRIO, in the ancient drama, ſignified an actor or comedian, but more eſpecially a pantomime, who exhibited his part by geſtures and dancing. See the article DRAMA.

HITCH, among ſailors, a certain knot or nooſe caſt upon a rope to faſten it to a poſt, ſhip, wharf, &c.

HITHE, or HYTHE, in our old writers, denotes a port, wharf, or ſmall haven, to embark, or land wares at; as Queenhithe, &c.

HIVE, *Alveare*, in country affairs, a convenient receptacle for bees. See BEE.

HIVING *of Bees*, the placing a ſwarm of bees in a hive, in order to have the profit of their labours.

When the ſwarm of bees has left an old hive, and is placed in form of a cluſter hanging down from the branches of ſome ſhrub or looſe buſh, the hiving is extremely eaſy, and may be done in half an hour after the time of their being ſtill, and calm in the cluſter; or it may be let alone till an hour or two before ſun-ſet, provided that the ſun do not ſhine too vehemently upon the place where they are, for that would diſquiet them, and force them to riſe; and in that caſe they uſually take a long flight before they ſettle again, and are very often loſt; this however may at any time be prevented, by placing an artificial ſcreen before them, compoſed either of a coarſe cloth, or of a few branches of trees well covered with leaves.

Thoſe authors who ſpeak largely of the œconomy of bees, give the new queen a ſet of officers, whoſe buſineſs it is to ſettle the proper places of reſort; and they pretend that theſe bees go out of the hive a day or two before the ſwarm iſſues out, in order to fix upon a proper place. This however appears but a romantic conjecture; and we uſually find the bees buſied in ſearch of a place, while the whole ſwarm is in the air; nor is it much to their credit, that they chooſe ſuch places as they do; for they uſually fix in ſuch as they can by no means ſubſiſt in.

It is commonly the branch of ſome ſhrub or tree that they ſettle upon; and we always find that they mean this as their ſettled habitation; for, however ſoon after they are hived, the rudiments and beginning of combs are found on it. It is true, they always leave thoſe places, if left to themſelves, in five or ſix days; but this is not till they find them ſo inconvenient that they cannot keep them, either from their being too much ſcorched by the ſun, or expoſed to winds and rain. The quantity of wax and honey left in theſe places, when they have quitted them, abundantly proves however that they meant them for fixed abodes.

When they are placed in a hive, they very ſoon find themſelves much better lodged than in the place they had provided for themſelves, and they uſually ſtay in it, and begin to work the next morning.

It might appear a very difficult taſk to get ſo large a number of bees into a hive, but it is much leſs ſo than it appears to be. They will often take poſſeſſion of the hive of their own accord, when it is hung over them; but the ſhorteſt way is to hold the hive under the branch where they are, and then ſweep them down into it. This may be done with the branch of a tree with leaves on it, or with the hand armed with a ſtrong glove, and the face covered. But there are country fellows who will go without any ſort of defence, and with their naked hand ſweep them carefully off the bough into the hive, which they hold in the other hand underneath.

It is not to be expected that the whole ſwarm will be thus ſwept peaceably into the hive; many will fly away, and many cluſters will fall beſide the hive to the ground. All this however creates no difficulty, for, the hive being turned bottom upwards, and ſet on the ground near the tree, with its edges a little raiſed above the ſurface, thoſe bees which fell in cluſters to the ground, will ſoon ſcrawl to their companions in the hive, and ſoon after thoſe which flew off, will deſcend and follow their example. If it happen however that ſome bees will obſtinately keep to the place where they at firſt fixed themſelves, the branch is to be rubbed over with the juice of ſuch plants as theſe creatures hate the ſmell of; ſuch are elder, rue, and ſome others. And if this does not ſucceed, there muſt be linen rags burnt under them, the ſmoke of which will ſoon drive them off, and make them join their companions, who find themſelves more at eaſe in the hive.

As it is neceſſary to render the places diſagreeable to the bees from which they are to be taken into the hive, ſo many people think it very proper to prepare the hive for their reception, by ſcenting it with ſuch things as they love the ſmell of. To this purpoſe they rub the inſide of it with baum and bean flowers, and daub a little honey in ſome parts of it. This however does not ſeem neceſſary, thoſe hives having been found to ſucceed full as well, where it was not done, as thoſe where it was.

If it be about noon that the ſwarm is taken into the hive, it muſt not be removed from the place before evening; and in the mean time it muſt be ſheltered from the too violent heat of the ſun, by the ſhade of the trees; or, if that be not ſufficient, a ſort of ſcreen muſt be made for it, either of a coarſe cloth properly ſupported, or of branches of trees with their leaves on. In this manner it muſt remain till ſun-ſet, and then the hive muſt be gently lifted up, and carried to the place where it is to remain, and the next morning the bees will be ſeen as buſy at their work in it, as the old ſwarm in their hive.

It ſometimes happens that the ſwarm is not placed ſo favourably as in the inſtance before-mentioned; they often hang themſelves in a long cluſter from the young ſhoots, or ſmall branches of high trees; and in this caſe many different expedients are to be uſed to hive them, according to the circumſtances of their poſition. The common method is for one man to climb the tree with a long ſtaff in his hand, and another to mount a ladder placed againſt the tree, and hold the hive under the ſwarm, while the other ſweeps them into it with his ſtaff; and when the bough on which they hang is ſo far from the body of the tree, that this is impracticable by the ladder, the hive is to be fixed to the end of a long pole, and by that means ſuſpended under the ſwarm while they are

ſwept into it. When all this is impracticable, by reaſon of the great height of the branch on which the ſwarm hangs, a large cloth is to be ſpread on ſome of the lower branches, and the whole ſwarm ſwept down in a cluſter upon it: this is then to be thrown carefully to the ground, and another perſon is to be ready there, to whelm the hive over the greater part of the cluſter, and the reſt will uſually ſoon creep into it, and join them. If they are ſlow in doing this, they are to be driven in by burning linen rags about the places where they fly, the diſagreeable ſmell of which will ſend them towards the hive, where finding their companions not incommoded with it, they will naturally remain.

Another method of getting a ſwarm from a branch of a high tree, is to cut off the branch with a ſaw, as gently and with as little diſturbance to the bees as poſſible. In this caſe, when the branch is off, a man may carefully deſcend with it, and the bees will not quit their hold, but will be all carried where he pleaſes with it, and may by that means be very eaſily put into the hive.

Sometimes the bees which go out in a ſwarm, fix upon a hole in a wall, or a hollow trunk of a tree, for the aſſembling themſelves in.

This is a much better choice for them than the branch of a tree, but it is much worſe for the perſon who is to hive them, for they are very difficult to be got out of theſe places. The common way of the country people is to attack theſe ſwarms in the middle of a cold night, and they then enlarge the opening from without, and, placing the hive under it, ſcoop the bees out of their neſt with a ladle, and put them into the hive.

It uſually happens that there are more than one young female in the hive, at the time when the ſwarm goes out; and it is not uncommon for two of them to go out with the ſwarm. In this caſe the ſwarm conſtantly divides into two bodies, and on whatever branch it fixes, there are ſeen two cluſters of bees, one placed near the other. Each of theſe is a complete ſwarm and has its female, but one of them is often much more numerous than the other; and as the bees always love to live in large communities, the bees of the ſmaller cluſter become tired of their condition, and by degrees join the larger; ſo that this is ſeen to increaſe, and the other to decreaſe in ſize every moment, till at length there remains no more of the ſmaller ſwarm than a few faithful creatures, forming a ſort of guard about the female. In this caſe it is in vain for them to think of forming a community by themſelves; and they finally, with the female, join the other ſwarm; ſo that the new ſwarm has two females. *Reaumur's Hiſt. Inſ.*

HOACHE, in natural hiſtory, a kind of earth approaching to the nature of chalk, but harder, and feeling like ſope; whence ſome think that it is either the ſame with our ſope-rock of Cornwall, or very like it. The Chineſe diſſolve it in water, till the liquor is of the conſiſtence of cream, and then varniſh their china-ware with it.

HOARSENESS, *Raucedo*, a preternatural roughneſs of the voice. The part affected is the aſpera arteria, particularly the larynx. This is a ſort of catarrhous indiſpoſition ariſing from a too great acrimony, thinneſs, or ſaltneſs of the lymph. Spermaceti, decoct. rapar. and rob. paſſular. are approved remedies in this diſorder.

HOASE, among ſailors, a piece of canvas ſewed together at the ſides, and made into the form of a tube, to convey water from one place to another; this is more particularly uſed in the hold or lower-apartments of the ſhip to fill the caſks which are already ſecurely ſtowed.

HOD, a well known inſtrument uſed by labourers to carry bricks, mortar, &c. in, at the building, or repairing of houſes, &c.

HOE, in country affairs, a tool made like a cooper's addz, to cut up weeds in gardens, fields, &c. This tool is commonly called the hand-hoe: for other ſorts of hoes ſee the next article.

This inſtrument is of great uſe, and ſhould be more employed in hacking and clearing the ſeveral corners, cracks and patches of land, in ſpare times of the year, which would be of no ſmall advantage thereto.

HOEING, according to Tull, is the breaking or dividing the ſoil by tillage, while the corn, or other plants, are growing thereon. It differs from common tillage, which is always performed before the corn or plants are ſown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This ſort of tillage is performed various ways, and by means of different inſtruments. Land which, before the tillage, would have yielded little, tho' the more it is tilled before ſowing, the more plenty of corn it yields, yet, if tilled only before the ſowing, will always have ſome weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reaſon for an after tillage, ſuch as that by hoeing. But there is another conſideration that yet more requires it; this is, that as ſoon as the ploughman has done his buſineſs, by ploughing and hoeing the land, after ſowing, the ſoil, of its own accord, begins to undo it all again by tending towards its original texture and ſpecific gravity again; the altering of which was the only buſineſs of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles, or new ſuperficies, is the great buſineſs of the plough and harrow; but, as ſoon as their uſe is over, the earth begins to coaleſce again into its own form, the particles unite together, and the artificial pores in a great meaſure cloſe up. The ſeed is nouriſhed in a worſe ground than it was firſt put into, and the more the plant grows up, and requires a larger ſupply of food, the worſe the paſture becomes. While nouriſhment is thus denied the growing plants, they are at the ſame time choaked with weeds, which, being of a hardier nature than they, will grow with leſs ſupplies, and therefore thrive more vigorouſly, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in ſome degree, with the uſe of tillage and dung to crops of uſeful plants; but they have ſo ill managed the time of giving theſe aſſiſtances to nature, that there is no doubt but one third part of the nouriſhment raiſed by dung and tillage, if it were given to plants and corn at many proper ſeaſons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of ſowing.

Nature, by what ſhe does in the animal œconomy, ſeems to point out to us ſomething like the remedying this by hoeing; for when the teeth, as the plough, have tilled that ſoil or maſs which is earth-altered; and when the ſaliva and the juices of the ſtomach have ſerved to divide and attenuate it, as the ſalts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhauſted by the numerous mouths of the lacteals, ſituate in the inteſtines. This laſt operation of theſe juices ſeems analogous to the meliorating the ſoil by hoeing, after the plants are grown, and are becomin fit for uſe.

Tranſplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by tranſplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be uſed to them with advantage, to their utmoſt ſtanding, and make them vigorous all the while.

The roots of a plant are all neceſſarily broken off in tranſplanting, and it requires ſome time for it to ſtrike a whole ſet of new ones; and if the earth about it is not kept thoroughly moiſtened all this time, the new formed roots will not be able to ſhoot, and the plant will ſtarve in the midſt of plenty: but, on the contrary, in hoeing, the ſame advantage of a new paſture for the plant is obtained, by the breaking the particles of the earth, and at the ſame time no more of the roots are broken off than can eaſily be ſupplied, and the reſt remaining in their places, the plant continues growing without that ſtop or decay, which muſt happen on tranſplanting, and which it recovers only by degrees. It is obſerved, that ſome plants are the worſe for tranſplanting: lucerne and ſaintfoin are never ſo good after tranſplanting, as when they are left in their native places, at the ſame diſtances; and finochia, removed, is never ſo good and tender as when it is not.

This laſt plant receives ſuch a check from tranſplanting in its infancy, that it has afterwards a diſeaſe like the rickets, which cauſes knots and ſwellings in it, that ſpoil it as a delicacy. All the tap-rooted plants ſuffer by tranſplanting; for it is neceſſary in this to cut off the long-main root, which afterwards, however good the ſoil may be, never arrives at the length it otherwiſe would have had, and which was neceſſary for the ſucceſs of the plant.

One great benefit of hoeing is, that it keeps plants moiſt in dry weather, the advantage of which to their growth is eaſily ſeen. This good office it performs on a double account. Firſt, as they are better nouriſhed by hoeing, they require leſs moiſture, and conſequently carry off leſs; for thoſe plants which receive the greateſt increaſe, having moſt terreſtrial nouriſhment, carry off the leaſt water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats, being ſown on a piece of ground well divided by tillage and dung, will come up and grow well without rains, when the ſame grains ſown on another part of the ſame land, not thus dunged or tilled, will ſcarce come up at all without rains, or if they do, will wait wholly for the rains for their growth and increaſe.

The hoe alſo, particularly the horſe-hoe, for the other does not go deep enough, procures moiſture for the roots from the dews which fall moſt in dry weather; and theſe dews ſeem to be the moſt enriching of all moiſture, as it contains in it a fine black earth, which will ſubſide from it in ſtanding, and which ſeems fine enough to be the proper pabulum, or food for plants.

A demonſtration that the tilled earth receives an advantage from theſe dews, which the untilled does not, is this; dig a hole in any piece of land, of ſuch a depth as the plough uſually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moiſt, while all the reſt of the ground, at the ſame depth, is dry. Or, if a field be tilled in lands, and one ſhould be made fine by frequent deep ploughings, while another is left rough by inſufficient tillage, and the whole ſhould be then ploughed a-croſs in dry weather, which has continued long, every fine land will be turned up moiſt, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly ſoaked with rain, will continue wet longer than fine tilled land adding to it, yet, this water ſerves rather to chill than nouriſh the plants ſtanding in it, and to keep out the kindly benefits of the atmoſphere; it leaves the ground much harder alſo than before, when it is finally exhaled from it; and when, at length, the earth is then hardened, it can receive no benefit from any thing leſs than a large of rain, which ſeldom falls till the ſeaſon of vegetation is over.

A fine hoed ground is not ſo long ſoaked with rain, ſo the dews never ſuffer it to become perfectly dry. This differs from the flouriſhing ſtate of plants in hoed ground, while others near them, but in ground not hoed, are ſtarved for want of nouriſhment. The common opinion againſt this, but obſervation proves it to be true againſt the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather for fear of letting in the drought, as they call it; whereas this is the only method of keeping away the drought, and without either this, or watering, they muſt fail in theſe ſeaſons. *Tull's Horſe-Hoeing Huſbandry.*

HOG, *ſus*, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which are theſe: The fore teeth are four in number, and are converging: thoſe of the lower jaw are eight, and are patulous: The dog teeth of the upper jaw are two, and very ſhort; those of the under jaw are ſingle, and exerted: the crown of the head is carinated, and the hoof is divided. See the article SWINE.

Beſides the common hog, there are ſeveral other ſpecies, as, 1. The American hog, with the back briſtly behind, and with a naked tail. 2. The muſk-hog, with a cyſt, placed on the back, in which is ſecreted a perfumed juice: its tail is naked. The babyrouſſa, with two teeth ſtanding on the forehead.

Hog's dung is, by Mortimer, reckoned one of the richeſt manures we are acquainted with, and the next in value to that of ſheep's dung, and is found to be equal in virtue to twice the quantity of any other dung, except this. The ancients ſeem to have been diſpleaſed with it, on account of its breeding weeds; but this is only accuſing it of being too rich, for any dung will do this when laid too thick. It is an excellent manure for paſture-grounds, and excels all other kinds of dung for trees. The farmers who uſe this dung for their lands, generally take care to ſave it, by well paving the ſtyes, and encreaſe the quantity by throwing in bean-ſtalks, ſtubble, and many other things of a like nature; and by good management of this kind many farmers have procured fifty or ſixty loads of excellent manure a year, out of a ſmall ſtye. The very beſt way of uſing this dung, is to mix it with horſe dung; and for this reaſon it is beſt to have the ſtye near the ſtable, that the two cleanſings may be mixed in one heap, and uſed together.

They have in many parts of Staffordſhire a poor light, ſhallow land, on which they ſow a kind of white pea: the land is neither able to bear this, nor any thing elſe, to advantage for their reaping; but when the peas are ripe, they turn in as many hogs as the quantity of peas will fatten, ſuffering them to live at large, and remain there day and night; in conſequence of this, the land will produce good crops of hay for ſeveral years afterwards; or if too poor for that, it will at worſt raiſe graſs enough to make it a good paſture-ground.

HOGSHEAD, in commerce, a meaſure of capacity, containing ſixty-three gallons.

HOISING, in the ſea-language, the act of drawing up any weighty body by the help of a tackle or complication of pullies.

HOKE-DAY, the Tueſday after Eaſter-week; which was the day on which the Engliſh conquered and expelled the Danes: this was therefore kept as a day of rejoicing, and a duty, called Hoke-Tueſday-Money, was paid to the landlord, for giving his tenants and bondmen leave to celebrate it.

HOLD, in ſhip-building, all that part of a ſhip's inſide which reaches from end to end, from the lower-deck to the floor or bottom; and contains the cargo, proviſions, &c.

HOLD-FAST, a large piece of iron, in the ſhape of the letter S, fixed into a wall, to ſtrengthen it. Alſo a tool uſed by joiners, carvers, &c. which goes through their benches, to hold faſt ſuch work as cannot be finiſhed by its being held in the hand.

HOLIBUT, the name of a very large flat fiſh, reſembling the flounder, but longer in proportion to its breadth.

HOLLAND, one of the United Provinces: it is about one hundred miles long, from north to ſouth, and ſcarce thirty miles broad; but enjoys the greateſt trade of any province in the world, and in point of ſtrength and riches is equal to the other ſix United Provinces. It is ſituated one hundred miles eaſt of England, and is bounded on the north and weſt by the German ſea, and on the ſouth by the provinces of Zealand and Utrecht.

HOLLAND, in commerce, a fine and cloſe kind of linnen, ſo called from its being firſt manufactured in Holland. See the article LINNEN.

HOLLOW, in architecture, a concave moulding, about a quarter of a circle, called by ſome a caſement, and by others an abacus.

HOLLOW-SQUARE, in the military art, a body of foot drawn up, with an empty ſpace in the middle for colours, drums, and baggage.

HOLLOW-TOWER, according to Hanis, is a rounding made of the remainder of two briſures, to join the curtain to the orillon, where the ſmall ſhot are played, that they may not be ſo much expoſed to the view of the enemy.

HOLLY, in botany. See the article AQUIFOLIUM.

HOLLY *Hedges* are a very beautiful evergreen and ſtrong fence, but liable to periſh in hard winters. It has been ſuppoſed, that the ſeverity of the cold, in theſe ſeaſons, was the occaſion of this; but a cloſer obſervation has ſhewn, that the miſchief is owing to the field mice,

mice, which in very ſevere ſeaſons, when they can get nothing elſe, diſbark the roots of theſe ſhrubs.

The method of preſerving theſe hedges, in ſuch ſeaſons, is found to be by clearing away the weeds which are a harbour to theſe little animals, and placing traps and boxes in proper places, with a paſte made of butter and rats-bane, daubed over their inſides, and holes made in their ſides no bigger than what the mice or rats, if there be any there, can creep into; and thus the vermin are deſtroyed, and the miſchiefs which might attend rats-bane being expoſed, are prevented.

Knee HOLLY, a name given to butchers broom.

Sea HOLLY, a plant more uſually called eryorgium. See ERYORGIUM.

HOLOCAUST, a burnt-offering, or ſacrifice, wholly conſumed by fire; of this kind was the daily ſacrifice in the Jewiſh church. This was done by way of acknowledgement, that the perſon offering and all that belonged to him, were the effects of the divine bounty. The heathens, who alſo offered holocauſts, probably conſidered them in the ſame light: and the diſpoſing of ſacrifices this way was the general cuſtom, till Prometheus introduced the cuſtom of burning only a part, and retaining the remainder for his own table.

HOLOGRAPH, in the civil law, an inſtrument entirely in the hand-writing of the perſon who ſigns it.

The word is Greek, and compounded of ολος, whole, and γραφω, to write.

HOLOMETER, a mathematical inſtrument for taking all ſorts of meaſures, both on the earth and in the heavens; it is the ſame with the pantometer.

The word is Greek, and compounded of ολος, whole, and μετρεω, to meaſure.

HOLY-GHOST, one of the perſons of the holy Trinity. See GOD and TRINITY.

Order of the HOLY-GHOST, the principal military order in France, inſtituted by Henry III. in 1569. It conſiſts of an hundred knights, who are to make proof of their nobility for three deſcents. The king is the grand-maſter, or ſovereign, and as ſuch, takes an oath on his coronation-day, to maintain the dignity of the order.

The knights wear a golden-croſs, hung about their necks by a blue ſilk ribband, or collar. But before they receive the order of the Holy-Ghoſt, that of St. Michael is conferred as a neceſſary degree; and for this reaſon their arms are ſurrounded with a double collar.

HOLY-THURSDAY, the ſame with aſcenſion-day. See ASCENSION.

HOLY-DAYS, the ſame with feſtivals. See the article FESTIVALS.

HOLY-ROOD-DAY, a feſtival otherwiſe called the exaltation of the croſs. See the article CROSS.

HOMAGE, in law, is the ſubmiſſion, loyalty, and ſervice which a tenant promiſed to his lord, when he was firſt admitted to the land which he held of the lord in fee: alſo that owing to a king, or to any ſuperior.

HOMAGE-JURY, a jury in a court baron, conſiſting of tenants that do homage to the lord of the fee.

This jury makes enquiry into, and preſentments of, defaults and deaths of tenants, and of admittances and ſurrenders into the lord's court.

HOMESOKEN, a privilege enjoyed by every perſon, in his own houſe or home, which ought not to be invaded.

HOMICIDE, in common law, the killing a man.

The word is Latin, *homicidium*, and derived from *homo*, a man, and *cædo*, to ſlay.

It is divided into voluntary and caſual. Caſual is either merely caſual, or mixed; the former is when a perſon kills another by pure miſchance, being about his lawful occaſions: it is accounted mixed, when there is negligence or ſome unwarrantable circumſtance attending the action. Voluntary homicide, that which is deliberate; and is either with a precedent malice, or without: the former is a felonious killing, with malice prepenſe, any perſon in the realm, who is under his majeſty's protection.

HOMILY, in eccleſiaſtical writers, a ſermon, or diſcourſe, upon ſome point of religion, delivered in a plain manner, ſo as to be eaſily underſtood by the common people.

At the time of the Reformation there were ſeveral of theſe homilies made and printed, and ordered to be read in ſuch churches as were not provided with a ſufficiently learned miniſter, in order to prevent unſound doctrine being taught in remote country places.

In the primitive church, homily rather meant a conference or converſation by way of queſtion and anſwer, which made part of the office of a biſhop, till the fifth century, when the learned prieſts were allowed to preach, catechize, &c. in the ſame manner as the biſhops uſed to do.

There are ſtill extant ſeveral fine homilies, compoſed by the ancient fathers, particularly St. Chryſoſtom and St. Gregory.

HOMODROMUS VECTIS, that kind of lever, in which the weight is in the middle, between the power and the fulcrum, or the power in the middle between the weight and the fulcrum. See LEVER.

HOMOGENEOUS, or HOMOGENEAL, denotes ſuch ſubjects as conſiſt of parts of the ſame nature, in contradiſtinction to heterogeneous, where the parts are of different natures.

The word is Greek, ομογενης, and formed of ομος, like, and γενος, kind.

HOMOGENEAL LIGHT, that whoſe rays are all of the ſame colour, degree of refrangibility and reflexibility. See COLOUR.

HOMOGENEAL NUMBERS, ſuch as are of the ſame kind.

HOMOGENEAL SURDS, ſuch as have one common radical ſign, as $\sqrt{}^2 a \sqrt{}^2 b$, or $\sqrt{}^3 b^3$, or $\sqrt{}^3 b^2$. See the article SURDS.

HOMOGENEUM COMPARATIONIS, in algebra, the known quantity in an equation, the ſame with abſolute number. It is ſo called to diſtinguiſh it from the other terms, which, though homogeneous, are not the quantities to which things are here referred.

HOMOLOGOUS, in geometry, is applied to the correſpondent ſides and angles of ſimilar and equiangular figures, which are ſaid to be homologous, or in proportion to one another.

HOMOLOGOUS THINGS, in logic, thoſe which agree in name, but are of different natures.

HOMONYMOUS, an appellation given to words which have two different ſignifications, being the ſame with equivocal terms.

HONE, a fine kind of whetſtone, uſed for ſetting razors, pen-knives, and the like. See COS.

HONEY, *Mel*, a ſweet vegetable juice, collected by the bee from the flowers of different plants, and depoſited in the cells of the combs; from which it is extracted either by ſpontaneous percolation through a ſieve in a warm place, or by expreſſion. That which runs ſpontaneouſly is purer than the expreſſed; a quantity of waxy and other impurities being forced out along with it by the preſſure, eſpecially when the combs are previouſly heated. The beſt ſort of honey is of a thick conſiſtence, a whitiſh colour, an agreeable ſmell, and very pleaſant taſte: both the colour and flavour are ſaid to differ in every degree according to the plants which the bees collect from.

Honey expoſed to a gentle heat, as that of a water bath, becomes thin, and throws up to the ſurface its waxy impurities, together with the meal or flower ſometimes fraudulently mingled with it, which may thus be ſeparated by diſpumation, ſo as to leave the honey pure. On continuing the heat, there riſes a conſiderable quantity of aqueous fluid, impregnated with the fine flavour of the honey: the inſpiſſated reſiduum, like the honey itſelf, diſſolves both in water and in rectified ſpirit, and promotes the union of oily and reſinous ſubſtances with watery liquors. By treating the inſpiſſated maſs with mouſſe, as practiſed by the ſugar-bakers for purifying ſugar, its unctuous treacly matter, the unctuous parts of the honey may in like manner be ſeparated, and its pure ſweet matter obtained in the form of a ſolid, ſaline, white concrete.

This juice is an uſeful ſweet, for medicinal as well as domeſtic purpoſes; more aperient and detergent than

ſimpler ſweet prepared from the ſugar cane; particularly ſerviceable for promoting expectoration in diſorders of the breaſt, and as an ingredient in cooling and detergent gargariſms. For theſe, and other ſimilar intentions, it is ſometimes mixed with vinegar, in the proportion of a about two pounds to a pint, and the mixture boiled down to the conſiſtence of a ſyrup; ſometimes impregnated with the virtues of different vegetables, by boiling in like manner with their juices or infuſions, till the watery parts of the juice or infuſion have exhaled and left the active matter incorporated with the honey. The boiling of honey, though it diſſipates great part of its odorous matter, and thus proves in ſome caſes injurious to it, is in ſome caſes alſo of advantage: there are particular conſtitutions, with which honey remarkably diſagrees, and in which even very ſmall quantities occaſion gripes, purging, and great diſorder: by boiling, it loſes of that quality by which it produces theſe effects.

HONEY-COMB, a waxen ſtructure full of cells, framed by the bees to depoſit their honey, eggs, &c.

There is ſomething very wonderful in the conſtruction of the cells in the honey-comb. Each cell conſiſts of ſix plane ſides, which are all trapeziums, but equal to each other. The bottom of the cell is contrived with three rhombus's HKDI, DEFI, and FIGH, (pl. LXXIV. *fig.* 1.) ſo diſpoſed as to conſtitute a ſolid angle at I, under the three equal angles DIH, DIF, and HIF; each of which is double the maximum angle of 54° 44′=DIK=DKI. Hence it comes to paſs, that a leſs quantity of ſurface is ſufficient to contain a given quantity of honey, than if the bottom had been flat, in the proportion of 4658 to 5550, as has been found by calculation; that is, nearly $\frac{1}{3}$ of the whole, ſo far as the figure of the ends of the cells extend in each, which fifth part of wax and labour ſaved, amounts to a vaſt deal in the whole comb. And if theſe admirable inſects knew their advantage, they could not more nicely obſerve the rules of the modern geometry. Hence we may obſerve, that though the method of diſcovering the maxima and minima of quantities by fluxions is a part of knowledge which the mathematicians have but lately acquired, and which they eſteem the ſublimity of human ſcience, yet this very thing was imparted to theſe inſects at the firſt creation of things.

The celerity with which a ſwarm of bees received into a hive, where they find themſelves lodged to their minds, bring their works of the combs to perfection, is amazing. There are vaſt numbers at work all at once; and that they may not incommode one another, they do not work upon the firſt comb till it is finiſhed, but when the foundation of that is laid, they go to work upon another, ſo that there are often the beginnings of three or four ſtories made at once, and ſo many ſwarms allotted to the carrying on the work of each. It would be a deſirable thing to ſee the bees at work, in making theſe elegant and regular fabrics; but it is ſcarce poſſible to ſee any thing of this kind diſtinctly, even with the advantage of glaſs-hives; for, as Mr. Reaumur obſerves, no bee ever works ſingly upon this occaſion, but wherever the fabric is erecting, there are numbers together trying to aſſiſt each other, and their motions are ſo ſwift, and ſo hid by their ſtanding before one another, that very little is to be ſeen of them. New bees are every moment going to the place, and old ones going away; and very frequently thoſe which arrive late are diſpatched away immediately after they arrive: there are only ſome very ſhort moments in which the glaſs of the hives can give a view of the creatures regularly employed at their work; for the moment one ſees a bee at work in building, that moment we ſee one either fly off, or elſe another get before her, ſo as to hinder the view: however, it is plain that the bee uſes her teeth in modelling and faſhioning the wax.

HONEY-COMB, in gunnery, a flaw in the metal of a piece of ordnance, when it is ill caſt and ſpongeous.

HONOUR-POINT, in heraldry, is that next above the center of the eſcutcheon, dividing the upper part into two equal portions. See the article POINT.

HOOD, in falconry, a piece of leather, with which the head of a hawk, falcon, &c. is covered.

HOOF, *Ungula*, the horny ſubſtance that covers the feet of divers animals, as oxen, horſes, ſheep, &c.

A horſe's hoof ſhould be of a round, not longiſh figure; and its ſubſtance ſolid, tough, high, ſmooth, without any circles, ſomewhat ſhining, and of a dark colour; for that which is white is commonly brittle; in ſhort, it ought to be of the colour of the hoof of a deer, and the whole foot round, but a little larger below than above, upright, and ſomewhat hollow on the inſide, and ſo diſpoſed that he may tread more on the toe than the heel.

The hoof of a horſe is either perfect or imperfect: an imperfect hoof is one that wants any of the above qualities; and, 1. May be broad and ſpreading out at the ſides and quarters; ſuch a horſe has, for the moſt part, narrow heels, and will ſoon be flat-hoofed; he will neither carry a ſhoe long, nor travel far. 2. Others are rugged or brittle-hoofed, which is a ſign that it is too hot and dry. 3. Some are long, which cauſes the horſe to tread all upon his heels, and by that means to breed wind-galls. 4. There are ſome crooked hoofs, broad on the outſides and narrow within, by which means the horſe is ſplay-foot. 5. Others have flat hoofs, and not hollow within, which give riſe to the inconveniencies above ſpecified in the firſt ſort of imperfect hoofs; but if it be too hollow, it will dry too faſt, and make him hoof bound. 6. When the fruſh is broad, the heels will be weak and ſoft, and the horſe will never tread boldly on the ground. 7. Some have narrow heels; theſe are the tendereſt of all, and the horſe will grow hoof-bound.

Bony HOOF is a round bony ſwelling, growing on the very top of a horſe's hoof, which is always cauſed by ſome blow or bruiſe.

The method of cure is, firſt to digeſt the ſwelling, either with rotten litter, or hay boiled in ſtale urine, or with a plaſter of ſtale wine lees, and wheat flour boiled together, in order to ripen it, and bring it to ſuppuration, or to diſſolve the tumor. If it come to a head, lance it in the loweſt part of the ſoftneſs, with a thin hot iron, to let out the matter; then tent it with turpentine, deer's ſuet, and wax, equal quantities of which ſhould be boiled together; and laying a plaſter of the ſame ſalve over it, to keep in the tent till it be thoroughly well.

HOOF-BOUND, this diſorder is a ſhrinking of the hoof at the top and at the heel, which makes the ſkin ſtare above the hoof, and grow over it.

This diſorder may happen to a horſe, either by keeping him too dry in the ſtable, by ſtreight ſhoeing, or by ſome unnatural heat after foundering.

HOOF-BRITTLE, an infirmity in horſes, proceeding either naturally, from the ſire or dam; or accidentally, from a ſurfeit falling down into the feet; or from the horſe's being formerly foundered.

For the cure, take unwrought wax, turpentine, ſheep's ſuet, and hog's greaſe, of each four ounces; ſallad-oil, a quarter of a pint; and of dog's greaſe, half a pound: boil them all together, and with this mixture, anoint the hoof well for two or three days, eſpecially at the ſetting on of the hair, and ſtop them with cow-dung and dog's greaſe, melted together.

HOOF-SWELLED, a diſorder that ſometimes happens by a prick, or a young horſe's being over-ridden, or too hard wrought, and which, if not ſpeedily removed, will beget a wet ſpavin.

For the cure, take the ſtrongeſt aqua-fortis you can get, and firſt file or draw away the old hoof ſomewhat near, with a file or drawing-iron; then touch what is left of the hoof, three or four dreſſings or more, with the aqua-fortis; and anoint the foot with an ointment made of one pound of hog's-greaſe; patch-greaſe, three quarters of a pound; Venice-turpentine, five ounces; new wax, three ounces; and ſallad-oil, three ounces; all melted together over the fire; and by anointing the coffin of the foot quite up to the top, you will cauſe a new hoof to grow upon it.

HOOK-PINS are bolts made with a ſhoulder at one end, and uſed by carpenters in framing: theſe are drove through the mortices and tenants of the work, prepared for building or wharfing.

HOP, *Lupulus*, in natural hiſtory, a plant of the reptile kind, whoſe flower is a principal ingredient in beer and other malt-liquors.

For the cultivation of hops, a rich, deep, mellow, dry

ſoil, more inclining to ſand than clay, is in general the beſt; and in particular, a black garden mould is excellent. Stiff clays, ſpewy lands, ſuch as are apt to be overflown by floods, hard gravels, ſtony grounds, very ſandy ones, and ſuch as are not at leaſt a foot and an half deep, are altogether improper for hops.

The beſt ſituation for hop-grounds is ſuch as inclines to the ſouth, or lies open to it, ſo that they may have the benefit of the ſun during the greateſt part of the day. It muſt alſo be open, for the air to have a free paſſage and circulation between the plants; and it ſhould be ſo ſheltered to the eaſt, north, and weſt, that neither the froſty winds in the ſpring may cut off the young ſprouts, nor the more ſtormy ones in ſummer and autumn deſtroy the full-grown hops.

The ground and ſituation being choſen, the next buſineſs is to prepare it for the planting. In many parts of England, when the ground is broken up for this purpoſe, the plough goes firſt, and men follow it with the ſpades, with which they dig one ſpit deep in the furrows where the plough has paſſed, throw up the earth thus dug, and ſo continue to plough and dig till the whole is done. Either this tillage, if it be well performed, or the deep ploughings, croſs-ploughings, and harrowings, by which careful huſbandmen prepare their land for corn, will fit this for being ſown with turnip ſeeds in the end of July, or beginning of Auguſt, and if the turnips are hoed twice, ſo as to be left about eight inches aſunder, they will yield a good crop, the weeds will be deſtroyed, and the ground will be rendered looſe and fine. Another good ploughing after the turnips are taken off, will, with the enſuing winter mellowing, render it fit for being planted with hops in the ſpring.

The beſt time to begin the ploughing is in October, in order that the ſoil may be properly prepared to receive the benefits of the winter's froſts, rains, and ſnows; after which, in the beginning of ſpring, it ſhould be well and deeply ploughed again, and well harrowed; and after another ploughing in March, which will be of very great ſervice, it ſhould be harrowed fine; and laid as even as can be.
